Secondly, becauſe the fleſh of the heart is wouen with all kindes of fibres. If therefore thoſe ſeuerall fibres doe in other parts ſome draw, ſome contract, and ſome looſen, either they are ſuperfluous in the heart (which to ſay, is to blaſpheme Nature) or elſe they haue the ſame vſes in the heart that they haue in other partes. VVee ſayed it proceeded for a certaine end, becauſe this faculty neither worketh *voluntarily* as the Animall, nor according to the power of the Agent in reſpect of that which ſuffereth, but for meere neceſsity. The ſtomack, although it be not hungry, yet it concocteth ſo much meat as is put into it, if it can: but the heart is not moued but as neceſsity vrgeth, making a pulſe either ſwifter or ſlower, as the vſe of Nature is to haue a ſlow or quick pulſe.

QVEST. III. *Of the manner of the motion of the Heart, and whether it ſtrike the Breſt in the dilatation or in the contraction.*

THus much concerning the cauſe of the motion of the heart. It followeth now to ſpeake of the manner of his motion, which is better knowne by the eye then by diſcourſe of reaſon: wherefore it is vſual with Anatomiſts, for the better obſeruation of this motion, to open Dogs aliue, that they may more diſtinctly ſee the manner thereof. From this *Autopſia* and witneſſe of the eye The maner of the motion of the heart.

will

will we vnfold this myſtery.

The 2. motions of the heart. The double reſt how neceſſary.

There are two motions of the heart, *Dyaſtole* or dilatation, and *Syſtole* or contraction; betwixt each of theſe is a reſt or ceſſation, one following the diſtention, the other following the contraction. For it is not poſsible that two contrary motions ſhould immediately ſucceed one another: but in the poynt of the refluxion or returne from one contrary to another there muſt needes be a reſt, otherwiſe there could be no beginning nor end of one motion diſtinct from the beginning and end of another; and ſo the motions could not be contrary which had no diſtinct beginning nor end particular to either of them, becauſe there is no reſt from which the beginning of the motion ſhould ariſe, or into which the end of the motion ſhould determine: wherefore whatſoeuer hath any reflexion, hath alſo ſome reſt before the reflexion.

An inſtance in the tyde.

A manifeſt inſtance hereof wee haue in the Tyde, which when it hath flowed to his height, ſtandeth ſometime at a ſtay before it begin to Ebbe, which ſtay we call a high water when no motion of the tide can be perceiued. But what is done in theſe contrary motions?

Dyaſtole what.

In the *Dyaſtole* the heart draweth bloud by the gate of the hollow veine into his right ventricle, and ayre by the arteriall veine into the left.

Syſtole what.

In the *Syſtole* the heart driueth out vitall ſpirites into the great artery, or fumed and ſmoky vapours together, with a ſmall portion of the ſpirits, by the venall artery.

In the *Dyaſtole* the ends of the heart are corrugated & contracted, the Baſis being drawne to the *mucro* or poynt, and the poynt to the Baſis: ſo that the heart becommeth ſhorter in his longitude, but is ſo amplified to his ſides, that his figure commeth neere to the ſpherical, which is the figure of moſt capacity. Contrariwiſe, in the *Syſtole* the ends of the heart are diſtended, but the ſides fall and flag, as it were, and ſo the heart becommeth longer, but narrower.

The vſe of the fibres of the heart.

Both theſe motions are performed by the helpe of the fibres; for the right which paſſe directly from the Baſis to the poynte, contracting themſelues make the dilatation. The tranſuerſe or circular ſtraighting the ſides, doe make the contraction; the oblique ſerue for retention, and make that double reſt whereof we ſpake.

How the values are in the motions.

Againe, in the *Dyaſtole* all the values are extended, in which diſtention, the forked values make many chinkes or crannyes as it were, but the *ſemi-lunarie* values do cloſe vp the ends of their veſſelles. In the *Syſtole* all theſe membranes are contracted, and then the forked ſhutte thoſe chinks and crannyes which they made when they were dilated, and the *ſemilunarie* being corrugated or wrinkled, leaue ſuch diſtances or rifts by which the bloud freely paſſeth forth.

Greater vſe of expiration then of inſpiration.

Moreouer, the dilatation of the heart is before the contraction in time, for ayre is firſt drawn in before the ſmoky excrement is ſhut out: and againe, inſpiration muſt needs be firſt, becauſe expiration is laſt, for the life vaniſheth in expiration.

But whether is of greater neceſſity? VVe anſwere, that in hayle bodies they are of alike neceſsity. In Agues eſpecially rotten and putrid there is more neceſsity of expiration, as wee ſee in thoſe that dye, their *Syſtole* and expiration is greater, becauſe Nature is more diligent to exclude that which is hurtfull, then to drawe that which is profitable; now wee know that the ayre that is drawne is familiar to the heart, but the ſmoaky and ſooty excrement is an offence vnto it.

Whether the heart ſtriketh the breſt in the *Dyaſtole* or in the *Syſtole*.

Laſtly, it is queſtioned whether it ſtrike the breaſt (which wee feele with our hand about the left breſt) in the dilatation or in the contraction.

Galens authority.

Galen ſeemeth to differ herein from himſelfe: for in one place he ſaith, *Quando rurſum euacuatum fuerit Cor, & in naturalem figuram recurrerit, tunc proſilit pectori, et percuſsionem facit, et ita concidens pulſum perficit*: that is, Againe when the heart is emptied, and returneth to his naturall figure and poſition, then it leapeth againſt the breſt, and maketh that percuſsion, and ſo falling accompliſheth that pulſe.

Reaſon to the authority.

To this authority may bee added this reaſon: when the heart is dilated it becommeth ſhort, and againe long when it is contracted. VVherefore when it is diſtended it goeth from the breſt, and when it is contracted it flyeth to the breſt, and ſo ſtriketh it: beſide, almoſt all Anatomiſts ſay, that the fleſh of the heart is more ſolid in the *mucro* or point, then in the Baſis; that in the violent motions of the breſt it ſhould touch the bone, to which it is very neere, and ſo be hurt, & ſo vitiate his motion: the point therefore ſtriketh the breſt, but experience and waight of reaſon is on the contrary part.

The conſent of anatomiſts.

What the trueth is.

The reaſons to proue it.

The reaſons are theſe: If you lay one hand vpon the breſt, and another vpon the wreſt, you ſhal perceiue in either place at the ſame time the ſame ſtroke; and this both *Galen* hath obſerued in the 3. ch. of his 3. Book *de præſag. expulſ.* & we daily proue it true by diſſections of

of liuing creatures; but it is most certaine, that the stroke of the artery is in the ende of the dilatation, for the end of the contraction cannot be felt; therefore that stroke of the heart we feele, is the end of the dilatation, not of the contraction.

It may bee obiected, that when the arteries are distended, the heart is contracted, and when the heart is contracted, then are the arteries dilated; if therfore you place your hand vpon the wrest or the temples, and there finde the stroke of the artery, and with the other hand vpon the breast finde also the stroke there at the same time, it must follow necessarily, that the heart is then contracted when the arteries are dilated, but the vanity of this obiection shall appeare in the next exercise. For the heart and the arteries are distended at the same time and in the same motion. Obiection. Answere with reference.

Moreouer, if the heart when it is contracted should strike the breast with his mucre or poynt, the stroake should not be felt at the left breast but somewhat lower, for the point of the heart reacheth to that place of the chest into which the midriffe is inserted. The brest therefore is beaten not with the poynt of the heart, but with the left ventricle when it is distended, which is the originall of the arteries; for when the poynt is gathered to the Basis in the *Diastole*, the heart is made larger, and so striketh the breast at the left Pap; but when it is contracted, the heart becommeth longer & narrower, and so falleth back into the chest; and of this also is *Galens* opinion in his Anatomicall administrations, and in those golden Hymnes of his, of the vse of the parts. Let vs proceed to the other difficulties which concerne the motion of this heart and arteries.

QVEST. IIII. *By or from what power the Arteries are moued.*

THE motion of the Arteries *Hippocrates* first of all others called σφυγμὸν, that is, the Pulse, & although he left indistinct precepts about it, yet was it not vtterly vnknowne vnto him, as some nouices would beare the worlde in hand, which may be prooued by many places, if it were necessary to wrastle in that floore: but we list not insist in that, but proceed. That the forme of the motion of this pulse is all one with that of the heart; for it consisteth of a *Diastole* and a *Systole*, and a double rest. *Hippocrates* first found the pulse and so named it. The forme of the motion.

In the *Diastole* the Arteries draw and are filled, and in the *Systole* they expell. The rest is double, vnlesse Nature bee prouoked either by a violent obiect, or by some external cause; for then the arteries may be moued together with an insensible rest, as in the pulse called *dicrotus ad vibrans*: so a stone which is throwne vpward, if it meet with a falling Tower, descends againe without any rest, although *Aristotle* thinketh that no violence can tie to contrary motions without some rest. *Aristotle.*

The vse of this pulsation is double; one greater, another lesser. The greater is for the conseruation of the naturall heate as well of the heart as of other parts: for by contractions whatsoeuer is smoky the arteries auoyde, and so the naturall heate is kept from suffocation, by dilatation they draw outward ayre into the body, by which the dissolution of the same heate is inhibited. The vse of pulsation double.

The lesse vse is, that in the braine may be ingendered the Animal spirit, for by the pulsation the spirits of life are carried into the *plexus choroides*. There is therefore the same vse of the pulse that there is of respiration, sauing that what respiration doth to the heart, that the pulse of the arteries doth to other parts, which as they neede lesse heate then the heart, so are they not so soone offended: for if the heart bee depriued of respiration, presently the creature perisheth, but the part dyeth not as soone as it wanteth the pulse.

The nature of the motion of these arteries is very obscure, and many things must bee resolued of and known, before we can attayne to the vnderstanding of so deepe a mystery. First of all, whence are the arteries moued from themselues or from some other. *Prapagoras* thought the arteries did moue of their owne accord, and that they had the same pulsatiue vertue that the heart hath, in themselues, not by influence. But this *Galen* disproueth by an obseruation; for sayth he, if an artery be cut ouerthwart, that part onely will pulse which remayneth ioyned to the heart; but that which is separated from the heart, will not beate at all. The nature of their motion obscure. *Prapagoras.* *Galens* instance

Erasistratus was of minde, that the arteries were not mooued by any proper power of their owne, but by the constraint of the heart, and that constraint hee meaneth not of any faculty but onely of some matter. *Aristotle* thought they moued, because of the feruour or boyling of the bloud contayned in them, whome some haue followed, because they know *Erasistratus.* *Aristotle.* The reasons.

that

Neither heat, nor ſpirits, nor bloud, are the immediate cauſes.

that the ſpirits are thoſe which make ſtrife & offer violence; and again, becauſe the veines neere the hart do not moue, which they would do (ſay they) if they had in them ſuch bloud as the arteries haue: but we will proue that neither heate nor ſpirite, nor boyling bloud can be the immediate cauſe of this perpetuall motion. For the heate, it either hath a body or hath no body; if it had a body, then the arteries that are neerer to the heart would ſooneſt be dilated; if it be onely a naked quality, then will it firſt heate thoſe things that are neere hand, and after that which is farther off. For heate is not of the number of thoſe formes which may in a moment be diffuſed as light, but his contrary is cold, which firſt muſt be expelled out of the ſubiect before it ſelfe bee receiued: but the pulſe is in a moment diffuſed through all the arteries, it is not therefore only from heate.

Not heat.

Not bloud.

It is not of ſpumous bloud; for then it would follow that where the bloud is more plentifull and hotter, there the pulſe ſhould be not onely more vehement, but more frequent alſo; and ſo the pulſes of the great arteries ſhould bee quicker then the pulſes of the ſmall: but experience teacheth, that all the arteries both great and ſmall doe mooue alike vnleſſe there be ſome hinderance; they are not therefore moued by the bloud contayned in them.

An inſtance.

Furthermore, intercept an arterie with a tye, and the part below the tye, though it ſtrut with ſpirits and thinne bloud, yet will not beate, becauſe the continuity of the faculty with the heart is intercepted; but as ſoon as the tye is vnlooſed, the artery will inſtantly beate againe, but the heate nor the humour can in a moment or inſtant flow from the heart into the vtter arteries. Adde to this, that if the arteries ſhould beate becauſe of the bloud contayned in them, then in all large pulſes there ſhould alſo be vehemencie, which is nothing ſo: For ſayth *Galen* in his Booke *de vſu pulſuum*, and in the fourth *de cauſis pulſuum*, there is a pulſe which is ſmall yet vehement, and there is likewiſe a pulſe which is great but languid and faynt, which variety cannot come from the heat.

There may be great, yet a faint pulſe.

Aſclepiades his opinion.

Aſclepiades acknowledgeth a faculty in the motion of the arteries; but whereas this motion is in dilatation and conſtriction, hee affirmeth that the diſtention onely is from the faculty, and the contraction from nature; that is, from the predominant element and from the waight, becauſe when the creature is dead the arteries doe fall. So bladders if they be filled with any thing they are diſtended, but they fall of themſelues: and all round and hollow bodies are dilated by ſome facultie, but afterward doe fall with the waight of their owne parts. On the contrary, thoſe things that are contracted by any faculty, that faculty ceaſing, they are againe dilated. Therefore if the arteries bee dilated by a faculty, then are they contracted by their grauity, and ſo on the contrary: wherefore they need not a faculty for both.

Herophylus his opinion.

Herophylus quite contrary will haue the contraction to be performed by a faculty, but the dilatation (ſayth he) is nothing elſe but the returne of the arterie to his natural poſition: Becauſe ſayth he, the arteries of dead carcaſſes being caſt into hot water, when they haue gotten the meaſure of heate that they had in the liuing body, will be dilated, but neuer fall, becauſe there wanteth a faculty: but they are both deceiued.

How both were deceiued.

For if both the *Dyaſtole* and *Syſtole* came not from the faculty, but from the conſtitution of the artery, then the artery ſhould euer keepe the ſame magnitude, and the ſame vehemencie of pulſation; but we ſee that the pulſe is now greater, now leſſer, as the ſtrength is great or little; ſometimes the *Syſtole*, ſometimes the *Dyaſtole* is greater, as the vſe of either is increaſed. There want not ſome who ſtriue to proue that the motion of the arteries is from the brayne, ſtanding vpon one authoritie of *Galens*, where hee ſayth in the 2. Booke *de cauſis pulſuum*, When in a man the pulſe beginnes to be convulſiue, preſently he is taken with a convulſion, which ſeemeth to intimate, that there is one originall of the faculty of pulſation, and of that to which convulſion doeth belong. But *Galens* owne obſeruation bewrayeth the vanity of this opinion. For if the brayne be compreſſed, ſence and motion will periſh, but the arteries will ſtill beate. If the nerue which commeth from the brayn to the heart bee cut or intercepted, the creature becommeth dumbe, but the arteries beate ſtill.

That the motion of the arteries is not from the braine.

The true cauſe whereby the motion is moued.

Seeing therefore that the arteries neither moue by a power of their owne, nor from the Elementary forme, nor onely from heate, nor from a ſpirit or ſpumy bloud, it remayneth neceſſary that they ſhould be mooued by pulſatiue power of the heart. For if they ſhould be moued by any thing ſaue by a faculty, their motion ſhould be not continual but violent: neither would there bee any attraction of ayre in dilatation, but the boyling bloud would take vp all the roome.

This

This Faculty or power pulsatiue is in a moment carried, not through the Cauitie but along the coats of the Arteries; and that it is carried in a moment this is an argument that all the Arteries are mooued with the same motion, all together in the same time vvhen the heart is mooued. If it be obiected, that *Galen* (in the 1. *de different. pulsuum, & de 2 prima cognitione ex puls.* speaking of those that haue hot hearts, and cold Arteries in whom the parts of the Arterie that are neerer to the heart are dilated sooner then those that are more remote) is constrained to confesse, that the pulsatiue power is mooued through the arterie & slowly by degrees. I answer, that the faculty floweth in a moment vnlesse it be hindred. But it may be hindred sometimes by his owne fault, sometimes by the fault of the Instrument; by his owne when the heate is weake, by the instrument when the arteries are either cold or soft or obstructed. It remaineth therefore, that when al things are aright disposed it floweth in an instant, and not through the Cauitie, but along the coats of the Arteries. *Galen* in the last Chapter of the Booke *Quod sanguis Arterijs delineatur*, giueth an instance from experience. If you put a Quill or Reede into the Arterie, which will fill the whole cauity, yet will the Artery beate; but if his coats be pressed with a Tie, it will cease instantly. If it be obiected that the Arteries in an Infant beate before the heart, and therefore the pulse is from the spirit, not from the heart: I aunswere, that the Infants Arteries do mooue by a vertue that proceedeth from the heart of the Mother: for the Arteries of the infant are continuall with those of the Mother, and receiueth as well life & the pulsatiue Faculty from her, as the Liuer and all the other parts do nourishment.

Which waie the Faculty is led.

What may hinder the motion of the heart.

An instance for experiẽce

Obiection. Solution.

QVEST. V. *Whether the Arteries are dilated, when the Heart is dilated, or on the contrary then contracted.*

THere ariseth now a more obscure, thornie, and scrupulous question, then the former, and that is, whether the Arteries and the heart are mooued with the same motion. For the explication whereof, we must first resolue that the Arteries are filled when they are dilated, and emptied when they are contracted, that they draw when they are dilated, and expell when they are constringed. The reason is manifest; For the vessels must needs draw with that motion whereby they are made most fit to receiue; but the vessells by how much they are more enlarged, by so much are they more capeable: now they are enlarged by dilatation; therefore, when they are dilated they draw and are filled: so that *Archigines* is no way to be hearkned vnto, who was of opinion that in the *Systole* the arteries do draw and are filled, and in the *Diastole* do expell and are emptied; whose argument for this was, because in inspiration the lippes are streightned, and the Nosthrils contracted: but whether this *Diastole* of the Arteries be at once and together with the dilatation of the heart, that is indeede a great controuersie. *Erasistratus* was the first that thought their motions contrary, that is, that when the heart is dilated, the Arteries are contracted; and when the heart is contracted, the Arteries are dilated.

A difficult question.

The Arteries are filled in their dilatatiõ

Archigines.

The first opinion.

Erasistratus.

Amongst the new writers, these haue sided with him: *Fernelius*, *Columbus*, *Cardane*, & *Scaliger*: and truely his opinion may be confirmed by authorities and reasons. *Galen* in his Booke *De Puls. ad Tyrenes* saith, that the Vitall Faculty dooth mooue diuers bodies at the same time with diuers motions, which can be vnderstood of nothing else but the motions of the heart and of the arteries. *Auicen Fen.* 1. *cap.* 4. *doctrin.* 6. affirmeth, that the vitall Faculty doth together dilate and constringe. The reasons beside these authorities are: In the *Diastole* the heart draweth blood by the hollow veine into his right Ventricle, and aer by the venall artery into the left. Therefore at that time the heart is filled, and the vessels are emptied. Contrariwise, in the *Systole* the heart expelleth the Vitall spirit into the arteries; therefore at that time the heart is emptied and the arteries are filled; but when the arteries are filled they are distended, and when they are emptied they fall: wherefore when the heart is distended, the arteries are contracted, and when it is contracted they are distended. Beside, there is the same proportion betweene the arteries and the heart, which there is betweene the heart and the deafe eare: but it is most certaine, which our eie-sight teacheth vs, that the motion of the heart, and of the eares of the heart are diuers; for when the heart is dilated, then those eares doe fall; and when the heart is contracted, then they are distended and filled: wherefore the heart and the arteries are mooued with a diuers motion.

Authorities.

Reasons.

The first

The second.

Thirdly, as attractions and expulsations are in other parts, so it is likely they are in the heart;

The third.

heart; but when the ſtomack driueth out the Chylus, the meſſentery veines do draw it, and therefore when the heart drieth out blood and the vitall ſpirit, then the arteries draw it; and ſo their motions are contrary.

The fourth. Fourthly, when the heart is dilated then becommeth it ſhorter, and draweth vnto it ſelfe the arteries that are continual with it and therefore maketh them narrower, but when the heart is contracted the arteries are dilated and become longer.

The fiſt. Laſtly, if one hand be placed vpon the breſt & another vpon the wreſt, the ſame ſtroke will at the ſame time be perceiued; but the ſtroke and percuſſion of the breſt is done by the contraction of the heart, for when it is contracted it commeth to the breſt and ſtriketh it: but when it is diſtended it becommeth ſhorter and recedeth from the Cheſt. Now the ſtroke of the Artery is not from the contraction, but from the dilatation. Wherefore the heart and the Arteries are moued with a diuers motion. But notwithſtanding all theſe reaſons, yet are we perſwaded with *Galen* in his booke *de vſu pulſ. & 3. de præſag. expulſ. & 6. de vſu partium*, that the heart and the Arteries are moued with the ſame motion. And this we are taught firſt by experience, then by ſtrong & inuincible force of argument.

The truth it ſelfe proued by

Experience. The experience is inſtanced by *Galen*, which euery man may make tryall of in himſelfe. If one hand be laide vpon the breſt and another vpon the wreſt, the ſame ſtroke will be perceiued at the ſame time; and beſide in diſſections of liuing creatures we haue often obſerued the very ſame. But beſide, theſe reaſons doe euince it. We haue already proued that the arteries are not moued by the impulſion of the bloud, not by the boyling or heate of it, but by a faculty and that not of the Arteries but yſſuing from the heart; therefore they are contracted by the faculty which contracteth the heart and diſtended by the ſame force and power by which it is diſtended. But if they were moued with diuers motions, it would follow that the dilating faculty muſt flow from the heart in the ſame moment wherein it is contracted, which no Philoſopher will dare to admit.

Reaſon. Firſt. Beſide, that motion is the ſame which hath the ſame efficient and finall cauſes: but the pulſatiue power is the ſame which moueth the heart and the Arteries; and the end alſo is the ſame, to wit, nutrition, temperation or qualification, and expurgation.

Second.

Third. Thirdly, the motion of the part and of the whole is all one; and a part of that being moued which is continuall with the whole, the whole is moued: as is ſeene in the ſtrings of Inſtruments: but the Arteries and heart are continuall together; wherefore if they bee moued by the heart as is moſt euident, then will it follow neceſſarily that they ſhall both be moued together by the ſame motion.

An inſtance.

Fourth. Fourthly, vnleſſe the heart and the Arteries were together diſtended and together contracted, the hart ſhould not be refrigerated in his dilatations, becauſe the Arteries being contracted there would follow an excluſion of the ſmoky excrments into the left ventricle, and ſo the hart and the artery ſhould mutually ſtriue, & their motion be in vaine.

Fiſt. Fiftly, it would follow that in the contraction the heart ſhould draw ayre from the dilated and diſtended arteries. For ſometimes the vſe of reſpiration being taken away, as in paſsions of the mother; the hart doth not draw ayre from the Lungs and the venall artery, becauſe then no ayre is drawne in by the mouth and the noſtrils, yet the hart moueth and the arteries beate. Now it is moued for the generation of vitall ſpirits, but this generation is not without the admiſtion of ayre: it draweth therfore ayre from the arteries not contracted becauſe then are the excrements expelled, but from the arteries diſtended. But if when the arteries are diſtended the heart be contracted, then the contracted heart ſhall draw from the diſtended arteries, and ſo ſhall the motions of the heart become contrary.

Sixt. Sixtly, this faculty is incorporeall, communicating it ſelfe in a moment: wherefore at what time the hart beginneth to dilate, it diſtendeth all the arteries, and ſo on the contrary.

Seuenth. Finally, the pulſes which are in anger, ſorrow and other paſsions doe ſufficiently ſhew that the heart and arteries are moued with the ſame motion. For, if when the hart is dilated the arteries ſhould be contracted, then in anger the pulſes ſhould bee ſmall, in griefe great; becauſe in anger the heart is ſomewhat contracted and therefore the arteries ſhould be but a little dilated. Contrariwiſe, in griefe the arteries ſhould be very much dilated becauſe the heart is ſtrongly contracted: but how falſe this is, common experience will witneſſe. Let vs therefore ſettle our ſelues in *Galens* opinion and determine, That the arteries are dilated and contracted when the heart is dilated and contracted.

What deceiued the former learned men. The ſtructure of the veſſelles of the heart, deceiued thoſe learned men which hold the con-

contrary opinion, together with the obscure maner of the hearts motion. For there being in the Basis of the heart foure notable vessels: the hollow veine, the arteriall veine, the venall artery, and the great artery: they imagined that the heart in his *Dyastole* did draw somthing from these foure vesselles, and in his *Systole* driue something into them all; and that therefore in the *Dyastole* of the heart they were all emptied that the heart might bee filled, and in the *Systole* of the heart they were all filled because the heart is emptied.

Beside, they seeme to haue been ignorant of the Efficient cause of the motion of the heart and the arteries. For they would haue the heart and the arteries to bee dilated because they are filled with ayre or bloud. But the trueth is, that the arteries are not dilated because they are filled; but because they are dilated therefore are they filled: onely the power & pulsatiue faculty which floweth from the heart distendeth the arteries, not the bloud contayned in them. For whether they be distended or contracted they remayne alwayes full of bloud: but if you shall thinke that they are distended because they are filled, then will it follow that at the same time they cannot be all distended; for how can that corporeall bloud bee carried in a moment from the heart to the arteries of the foote? I will giue you for illustration of this matter an elegant example. The Smithes bellowes because they are dilated are therefore filled with ayre; and the chest because it is distended by the animall faculty is presently filled; but purses bagges and the hogges bladder with which boyes often play themselues, are distended because they are filled.

What the trueth is.

The arteries in both motions are full of bloud.

A fit example

But we must carefully marke, that whereas there are foure vesseiles of the heart, onely the arteries is filled because it is dilated: the other three are distended because they are filled, and doe fall because they are emptyed; because onely the arteries haue the motion of *Systole* and *Dyastole* from the faculty of the heart, the other vesselles are immouable. And this is the reason why when the heart is contracted the left eare is dilated, because the eare is a kinde of store-house of ayre and bloud which suddenly rush into it; from the which when the heart draweth bloud or ayre, it is of necessity that it should contract it selfe.

The former distinction concerneth only the arteries.

Why the left eare is dilated when the hart is contracted.

These things being determined, it will bee easie to make satisfaction to whatsoeuer is obiected on the contrary part. The authorities of *Galen* and *Auicen* are not contrary to our determination, for they call the heart and the arteries diuers moouable bodies, which at the same time are mooued with diuers motions; for they are dilated and contracted at once and together by the same vitall faculty. And I imagine that *Galen* and *Auicen* spake this against the antients, who sayde that onely the dilatation was from the faculty, but the contraction from the Elementary forme and from the waight of their bodies. The reasons are thus to bee answered. The arteries are not distended because they are filled but are filled because they are distended; neither doe the arteries fall altogether when they are contracted but retayne still their cauity; and the plenty of the matter is more which issueth from them then that which is receiued into them: the arteries therefore are not dilated by the influence of the matter which goeth out of the heart.

Satisfaction to the authorities alledged.

The reasons answered.

The first.

The second argument is of no moment: for there is not the same reason of the heart and the eares thereof; for the eares expell nothing, but the arteries expell more at that time then they receiue; beside, the eares are dilated because they are filled, but the heart & arteries are therefore filled because they are dilated: and this did *Hippocrates* silently insinuate where he sayth, The heart is mooued by his whole Nature, that is, by his proper faculty: but the eares doe priuatly swell and fall againe; that is, as they are filled or emptied of ayre and bloud.

The second.

Hippocrates de Corde expounded.

To the third reason we thus make satisfaction; in other parts the attractiue and expelling vertues are in-bred, but contraction and dilatation the arteries haue by influence.

The third.

The fourth reason instanceth but in a light contraction, which is into length not into bredth.

The fourth.

Last of all, the last reason is against experience, for we haue before proued that the brest is beaten in the dilatation, the left ventricle being largely displayed.

The last.

QVEST. VI. *Of the generation of the vitall spirit, and by what wayes the bloud goeth out of the right into the left ventricle of the Heart.*

Of the vitall spirit.

WEE haue hitherto prooued that the motion of the Heart and the Arteries is one and that a perpetuall motion, consisting of a *Systole* a *Dyastole* and a double rest, arising from a naturall pulsatiue faculty of the Soule residing in the heart, there assisted by the structure of the fibres and thence deduced by influence or irradiation into all the arteries at one instant, not through the cauity but along their coates. Now becausse all this curious and maister-peece is wrought by Nature, onely for the generation of vitall spirits; it is more then requisite that we vnderstand what this spirit is, & how generated. We will not trouble you with many things hereabout, but those we will insist vpon shall not be triuiall and ordinary but hewen out of the deepe quarries, vnueyled from amongst the most secret mysteries of Nature. That there is a vitall spirit in perfect creatures no man euer denyed. *Hippocrates* in his Booke *de Generat.* & *de principijs* first put vs in minde of it, *Galen* hath a thousand times inculcated the same.

All physitians agree that there is a vitall spirit.

The prince of the Arabian tribe *Auicen* hath set his seale vnto it; and all the multitude of Greek and Arabian Physicians haue added their suffrages. And amongst the later writers, though some haue doubted concerning the Naturall and the Animall spirites, yet all with a ioynt consent allow of the vitall. There is therefore a vitall spirit which is primarily seated in the Left-caue or denne of the heart as it were in a shoppe or work-house; and from hence it is diffused by the arteries as by conduits or pipes into the whole body. This spirit cherisheth the in-bred heat of euery part, quickens it when it becommeth drowsie, bringeth it forth when it lyes hid, and being spent or wasted restoreth it againe.

The office of this spirit.

This spirit whilest it shineth in his brightnes and spredeth it selfe through all the Theater of the body as the Sunne ouer the earth, it blesseth all partes with ioy and iolitie and dies them with a Rosie colour; but on the contrary when it is retracted intercepted or extinguished, all things become horred wanne and pale and finally doe vtterly perish. So wonderfull and almost so heauenly are the powers of the heat and spirit, that the diuine *Senior Hippocrates* applying himselfe to the rude capacity of the people (as *Galen* witnesseth, hee sticketh not often to doe) calleth it the Soule, that is, the chiefe instrument of the Soule.

Hippocrates calleth the spirit the soule.

The Soule of a man (sayth hee) is seated in the left ventricle and is nourished not by meates or drinkes from the lower belly, but by a most pure and bright substance out of the separation of the bloud; as if he should say, it is creamed as it were off from the bloud, and by the heat of the heart rarified into an ætherial consistence. For the Soule it selfe being a denison of heauen (τῦ γὰρ ἐγένος ἐσμέν, for wee are also of his generation) how could it be tyed to this house of clay vnlesse it were by the mediation of some middle Nature, participating as neere as mortality will suffer of the puritie of the Soule and yet hauing his originall from the body, that the Soule might haue a nimble and agile instrument to follow her sudden designes.

Paul. The spirit is the *medium* betweene the soule and the body.

By the Soule therefore in this place, *Hippocrates* meaneth the vitall spirite, which is nourished with pure and attenuated bloud, that is, Restored; for therein lyeth a mystery: that the nourishment of the spirit is not, in all things, like the nourishment of the partes, but rather is an illumination, vnition and establishment of them, as wee shall heare afterward.

The vses of the vitall spirit within & without the heart.

The vses of this vitall spirite are according to his nature deuine also, both within and without the heart. In the heart to bee the principall instrument of the functions of the heart; without the heart his vse is double: one to bee the subiect of the heat of the heart which wee call *Calor influens* the influent heate, which it may receiue as the ayre doeth the light and so exhibite it to the whole body; and the other to bee the matter of the Animall spirit.

Calor influens.

His matter double.

This vitall spirit hath a double matter aery and sanguine, for it is made as *Galen* saith in his seuenth Booke *de placitis Hipp. & Platonis*) of aer and blood mingled together. That it is made of aer *Hippocrates* taught in *Epidemijs* when he saith; Such as is the aer such are the spirits; a foggie and cloudy aer engendreth a grosse and duskish spirit: and againe *Hippocrates*; The Southwinds dull the hearing, are misty and breed a dissolution of the spirites.

Ayre.

This

This aery substance alone cānot contein within the body the vital heat; It is necessarie therfore that there should be an admistion of thin and subtle blood which should restraine the impetuous force of the aire. And both these matters before they come vnto the left ventricle of the heart stand in neede of preparation. The aire drawne in by the mouth and the nose is prepared in the Lungs his vessels and his whole soft rare and spongie substance, & by a long delay doth acquire a qualitie familiar to the in-bred spirite. This aire thus prepared, is conueyed by the venall Artery into the left ventricle. And this is the preparation of the aer, these the passages by which it is conducted to the heart.

Bloud.

How & wher the aer is prepared.

Concerning the preparation of the blood, in what place it is made and accomplished and by what waies it is deriued into the left Ventricle, the Anatomists do striue with implacable contention. I haue read and turned ouer many of the Monuments both of the Ancients and also of later Writers and I finde foure opinions euerie one repugnant to another.

How the blood is prepared.

4. Opinions.

The first and the most ancient is that of *Galen*. He thinketh, that the blood is carried through the Hollow veine which with an open mouth gapeth into the right ventricle of the Heart as into a Cisterne, and is there boyled attenuated and subacted, and then a part of it is sent by the arteriall veine into the Lungs & distributed into thē for their norishment, the remainder is carried through the middle partition, which like a wall seuereth the two Ventricles asunder, into the left, where it is by the in-bred vertue of the heart mingled with the aer and doth there acquire the forme of a vitall spirit, assisted partlie by the inbred spirit of the heart, partly by an exceeding heate & flame whereby it is wrought as in a Furnace into a more pure Elementary forme. This opinion of *Galen* which of all the rest is most true, some of later times haue condemned. For they do not thinke it possible that in so short a time so great a quantity of blood as is sufficient for the generation of vitall spirits for the vse of the whole body can sweate thorough the wall of the heart into the left ventricle, there being no apparant and sensible passages, and the wall also beeing very thicke and solid.

The first and trueſt of *Galē*.

Obiections.

Moreouer they obiect, that if it should be so, then the labour of the heart were vaine and idle; for why shold not the blood and aire being thus attenuated repasse again out of the left into the right, seeing the same way is open for them, the same passages & no values or gates to hinder it? But these Obiections are of lesse weight then that they shold weaken the authority of so great an author of our Art: and *Galen* himselfe foresaw (in the 15. cha. of his 3. Booke *De Facultatibus Naturalibus*) that there would be some which would make these childish Obiections. Wherefore in another place he thus elegantly explaineth him selfe. Out of the right Ventricle that which is the thinnest is drawne through the pores or passages of the partition, whose vtmost ends can hardly be perceyued, because after death all such yea all other passages that are not distended by the matter conteined in them, doe fall together. But that it is this way transmitted hence it is manifest, because Nature neuer endeoureth any thing rashly or in vaine; but there are certaine dens in the fence or partition, deep bosomes very many which grow narrower to their outlet, by which the blood may freely and with a large streame yssue out of one ventricle into another. But the cause why this blood doth not returne againe out of the left into the right side, may be well referred to the peculiar force and vertue of the heart.

Galens minde explained by himself.

The left Ventricle drawes this bloode and retaineth it by an inbred propriety and for a while enioyeth it, and then thrusteth it foorth into the Tunnels of the arteries. So the blood which either hath sweate through the coates of the veines, or is powred foorth at their mouths into the substance of each part, returneth not into the veines againe because it is reteyned and receyued into the substance of the part. The truth of this opinion, albeit it be most cleare of it selfe; yet it will bee better manifested vnto vs after wee haue taken knowledge of other mens conceites and discussed them to the full.

The second opinion therefore is that of *Columbus*. That the bloode indeede is attenuated and prepared in the right Ventricle of the heart, but is carried into the left ventricle by other passages and not through the pores of the *Fence* or partition. And what neede we seeke for so small and secret pores, when it hath an open channell, the arteriall veine, which (sayth he) carryeth all the bloud out of the right ventricle into the Lungs, where a part of it is distributed for their nourishment, the rest is returned into the venall artery, and from it together with the ayre into the left ventricle; and this opinion of his he strengthneth with two reasons. The arteriall veine (sayth he) is greater then was necessary for the nourish-

The second opinion of *Columbus*.

ment of the Lungs, it is therefore like that it was deſtinated alſo for the conueiance of the bloud for the generation of the vitall ſpirits. His other reaſon is this: there is alwayes in the venall artery thinne and arteriall bloud; this bloud is receiued not from the left ventricle, for the three-forked Membranes wil not ſuffer it; therfore frō the veine of the Lungs.

The anſwere to *Columbus* his First reaſon.

Theſe things are very probable and cloked with the vaile of truth, yet not to be admitted for currant. For whereas he ſaith the veine of the Lungs is larger then their ſmall body ſtands in need of, we vtterly deny it. For the rare lax and ſpongy ſubſtance of the Lungs is eaſily diſsipated, it is alſo continually moued, and by reaſon of the neighbourhood of the heart is eaſily inflamed; whence comes a huge expence of the threefold nouriſhment; but where there are great goings out, there alſo had need be great commings in: now the bloud could not come plentifully in but by a wide veſſell, therefore the veſſell of the Lungs was of neceſsity very ample and large. Beſides ſaith *Galen*, Nature made this veſſell large,

Lib. 6. de vſu part. cap. 10.

that how much was abated in the nouriſhment of the Lungs by the veſſels thickneſſe, ſo much might be recompenced in his amplitude and largenes.

To the ſecōd.

To the ſecond reaſon we may anſwere thus: The bloud that is found in the venall artery is a portion of the vitall ſprits and arteriall bloud which the heart poured foorth into the ſubſtance of the Lungs: for all life being from the heart and the vitall ſpirit, and no deriuations of veſſels from the great arterie vnto the Lungs; it is likely yea neceſſary that vitall ſpirits ſhould bee conueyed to the Lungs by the venall artery, neither is there any reaſon they ſhould obiect the oppoſition of the thre-forked Membranes; for there are but two in the orifice of this veſſell, becauſe it behoued not that it ſhould bee perfectly cloſed vp.

An obiection. Anſwere.

Happly they may obiect the contrary motions and the mixture of ſmoky vapor with the ſpirits, but they attribute very little to the wonderfull prouidence of Nature and are ignorant what the diuers appetites and attractions of particular parts can do. The veines of the meſſentery do together and at once diſtribute Chylus and bloud: Milke paſſeth ſometimes out of the breſts all along the trunke of the hollow veine yet is not mingled with the bloud, but paſſeth out by vrine pure and ſincere; and as we ſhall by and by proue, the matter and quitture of thoſe we call *Empyici* is purged by the left ventricle of the heart and ſo through the arteries into the kidnies and the bladder, yet is not the vitall ſpirit ſtained with this filthineſſe if all things be in good order with the patient: and ſo much for *Columbus*.

Pure milke auoyded by vrine.

The third opinion of *Botallus*.

The third opinion is that of *Iohn Botallus*, the french Kings Phyſition, who boaſteth that he found a paſſage open which no man euer knew, out of the right deafe eare into the left, by which he imagineth that the bloud prepared in the right ventricle paſſeth into the left. This he ſaith is very euident in Calues and other young creatures, but in man & creatures that are growne, it is not ſo open.

Confuted.

This opinion of *Botallus* hauing no reaſons to eſtabliſh it, ouerthroweth it ſelfe; for if Nature made this paſſage for this vſe, to transfuſe the bloud from the right ventricle vnto the left; then ſhould it be manifeſt in all creatures in all times of their life, yea the creature growing large and the naturall heat daily increaſing the paſſage alſo ſhould grow more manifeſt as whereof there is euery day greater vſe. But *Botallus* confeſſeth it is not found in Oxen nor in creatures of any growth.

Beſide, this paſſage is in the orifice of the hollow veine, how therefore ſhould the attenuated bloud flow backe from the right ventricle vnto the veine, ſeeing there are three values open without and ſhut within, which doe admit the bloud indeed into the right ventricle but will not ſuffer it to flow backe into the hollow veine? This good honeſt man was ignorant of the vſe of his paſſage, which *Galen* acurately deſcribeth firſt of al men in his golden bookes of the vſe of the parts.

Botallus ignorant of the vſe of the paſſage he thinkes hee found.

My ſelfe haue ſeene this paſſage very often with the other arteriall pipe, but they ſerue onely for the Infant before it be borne, becauſe his life and nouriſhment is much vnlike to that it is afterwards, and therefore after the birth the paſſage is altogether ſhut; & the pipe ſo dryed vp that a man would deny that euer any ſuch thing was; the vſe of this paſſage & pipe we haue at large deſcribed aboue, and thether do we tranſmit the Reader that is not ſatisfied concerning them.

The fourth opinion of *Vlmus*.

The laſt opinion of the preparation of the bloud, is that of *Vlmus* a *Phyſition of Poyto*, who ſet out a very eligant booke of the ſpleene. He is of opinion that the arteriall bloud is concocted, attenuated and prepared in the ſpleene, and thence conueied into the great artery and ſo to the left ventricle of the heart, where, by an admirable and myſticall worke of Nature it is mixed with the ayre already prepared by the Lungs. I muſt needs confeſſe

that the opinion of *Vlmus* pleaſed me wondrous well, both for the nouelty of the conceite, as for that he handled the matter with great ſubtilty of argument, and deepe diſcourſe; but becauſe he leaneth vpon vnſound foundations to eſtabliſh a new doctrine, which do ſhadow the brightnes of the Art of Anatomy, it wil not be amiſſe to recal the principal points of it to the touch-ſtone in this place. A ſubtile diſputation.

Firſt of all, hee thinketh that the bloud cannot paſſe out of the right ventricle into the left by the fence or partition, becauſe (ſayth hee) if this way were not ſufficient in a tender Infant in whome the veſſelles are more laxe and the ſubſtance of the wall more rare and thinne, and wherein there is leſſe diſsipation or waſt of ſpirit; then ſurely it will much leſſe ſuffice in an older man: but this way is not ſufficient in the Infant, ſo that nature prouided another; to wit, two arteries, which are carried from the Nauel to his crural arteries. Therefore in a growne man it is neceſſary there ſhould be other more open paſſages.

An argument truely moſt ſubtile, but moſt falſe and ſtuffed with error: For in the Infant, the bloud doeth not ſweate through from the right ventricle to the left, becauſe there is no generation of vitall ſpirits in the ventricles of the heart; but the Infant draweth the mothers ſpirite by the vmbilicall arteries, which is diffuſed into all the ſtreames of the great artery. The Lungs are not nouriſhed with pure and thin bloud but with thicke, carried vnto them by the hollow veine; wherefore from that hollow vein to the venal arterie there is a cleare paſſage, and a conſpicuous pipe from the great artery to the arteriall veine, by whoſe interpoſition the veſſels of the heart in the Infant are vnited. *Anſwere to Vlmus.*

The opinion therefore of *Vlmus* is falſe, becauſe in the Infant there is no ſhop of the ſpirits, neither doth the orifice of the hollow veine powre out bloud into the right ventricle of the heart; for that, as *Galen* ſayth in the 15. Chapter of his 6. Booke, *de vſu partium*, the Lungs in an Infant are redde, denſe and immouable, and are nouriſhed with thick and groſſe bloud.

Secondly, the membranes placed in the orifice of the great artery (which hee calleth not well *three-forked*, for the values of the hollow veine and the venall artery one are three forked, the reſt are *ſemicirculer*) he doth not imagine are made to that end that they ſhould prohibit bloud for going out of the great artery into the hart; becauſe while the Infant was in the wombe, they hindered not the arteriall bloud from entring into the left ventricle of the heart. But here *Vlmus* offendeth at the ſtone at which he ſtumbled before, for nothing floweth into the ventricles of the Infants heart by his foure orifices. Not bloud by the hollow veine, for what need is there of his attenuation, when the Infants Lungs are nouriſhed with thick bloud? Not ayre by the venall artery, for the Infant breatheth not in the womb. Not arteriall bloud by the *Aorta* or great artery, for this labor were vaine, becauſe in a moment it ſhould bee thruſt backe into the ſame *Aorta* againe: adde to this that there ſhould haue beene no neede of that arteriall canale or pipe going from the great artery to the arteriall veine, vnknowne to thee *Vlmus* as I ſee, and almoſt to all Anatomiſts. Nothing goeth into the Infants heart out of any of the veſſels.

Thirdly, whileſt *Vlmus* aſſenteth to *Botallus*, and faſhioneth to himſelfe a peculiar vſe of that hole or paſſage, he walloweth in the ſame puddle with him and deſerueth the ſame reproofe *Botallus* had. In confuting of *Columbus* he is moſt ſubtile, at length he bringeth to the birth his witty conceite which he trauelled with, and after many ſharpe throws and pinches is deliuered of it. To wit, that in the ſpleene the arteriall bloud is prepared, becauſe the ſpleene is made as it were of a woofe and web of veines and arteries inexplicably wouen together: that when it is ſo prepared it is ſucked away by the arteries and carried into the trunk of the great artery, and ſo into the left ventricle of the heart: but there be indeed many obſtacles which will hinder this ready paſſage if wee will but ſtay a while and follow the ſtreame a little. *Vlmus* opinio.

Firſt of all, in the orifice of the great artery there are three membranes ſhut without againſt it, ſo that by them the arteriall bloud cannot paſſe: This our very eies teach vs, and beſide our great *Dictator*, in his Booke *de Corde*, hath in direct wordes deliuered the ſame. *Vlmus* I know alſo will deny this vſe of the values, and yet I know alſo hee will not ſay that Nature formed them in vaine. I ſay then, that if they doe not altogether interclude or hinder the egreſſe and regreſſe of the bloud; yet as he himſelfe is conſtrayned to confeſſe, they break and ſtay the aboundant and violent influence of the ſame; which if they doe, then cannot the whole matter of the vitall ſpirits bee brought from the ſpleene by the great artery vnto the left ventricle of the heart; becauſe ſeeing the generation of the ſpirits muſt bee ſudden and aboundant, their matter alſo had neede to bee miniſtred with a full How it cannot be true.

ſtreame, and not drop or ſipe by degrees into the heart. Furthermore, in the ſtructure of the heart there is one point of Natures excellent worke-manſhip, that draweth by one veſſell, and expelleth by another. It draweth blood by the Hollow-veine, the ſame it expelleth by the Arteriall veine; it draweth aire hy the venall artery which it mingleth with the blood, and expelleth the vitall ſpirit into the great artery; but if by the great arterie it ſhould draw the matter of the ſpirites, and almoſt in the ſame moment ſhoulde expell the ſpirit into the ſame great artery againe, there would be a mixture of thoſe iuices, and in the arteries would there alſo be perpetually two contrary motions, one of the bloode, aſcending from the ſpleene to the heart, another of the arteriall bloode deſcending from the heart to the ſpleene, which as we admit may be ſometimes in criticall euacuations & in notable Maiſter-priſes of Nature, ſo we deny it to be perpetuall, but the generation of ſpirits is perpetuall.

Obiection. *Vlmus* will obiect, that the venall Arterie leadeth aire vnto the heart, and ſhutteth alſo out into the Lungs ſmokie vapours, together with ſome portion of bloode: but we will anſwere that there is not the like reaſon of aire and of blood. Aire by reaſon of his ſubtilitie and fineneſſe can paſſe through the blood and the coats, which blood cannot do.

Anſwere.

An argument Moreouer, if the Arteriall blood be prepared in the Spleene, and not in the right ventricle of the heart as *Galen* thought, why doth the Hollow veine open into the heart with ſo wide a mouth? Was it onely for nouriſhment of the Lungs? No verily, for the orifice of the Hollow veine is much larger then the orifice of the arteriall veine, as *Galen* ſaith (in his 3. booke and 15. chapter *De facultate Natural.*) was it for the nouriſhment of the heart? Nothing leſſe. For the heart hath a peculiar veine, called the Crowne veine by which it is nouriſhed; therefore that patent orifice of the Hollow veine at the right ventricle of the heart, was ordained to caſt in the ſeede of the ſpirites into the wombe of the heart, where they are forced and ſent out into the little world of the bodye. Finally, from hence I gather, that the Spleene was not ordained for the preparation of the Vitall ſpirites, becauſe the Spleene is very ſubiect to obſtructions, not by reaſon of his veſſels which are very ample and large, nor by reaſon of his *Parenchyma* or fleſh which is rare and ſpongie, and therefore by reaſon of the fœculent and muddie humour conteined in it: but how ſhall it ſerue for the expurgation of the droſſe and the bloode and for the preparation alſo of the ſame blood. Wee therefore conclude, that the bloode is prepared in the right Ventricle of the Heart and thence is deriued into the left by the holes and nooks of the partition wall.

Why the ſplene cannot prepare the blood for the heart.

The concluſiō

QVEST. VII. *Whether the Matter and Quitture of thoſe that are called* Empyici *may be purged by the left Ventricle of the Heart and the Arteries, and how it is purged by the Vrine, by the Seidge and by Apoſtemation.*

Who be *Empyici*. THis Queſtion hath wrung the wittes of many Schollers a long time, notwithſtanding according to the meane modele of our wit, we will heere, if it may be vntie that knot. Wee call thoſe *Empyici* with *Hippocrates*, who haue an impoſtume (as we call it) or a bladder broken in the ſide or the Lungs, the matter of which is powred out into the cauity of the Cheſt, & there is kept and floweth vp and downe, ſo that with the impurity of it the Lungs are as it were laid in ſteepe.

This quitture may be purged 4. wayes. This purulent matter, according to the doctrine of *Hippocrates* may be purged 4. waies, Vpward by the mouth, by the Vrine, by the Seidge and by Apoſtemation. The vpward excretion is by a proper motion of the Cheſt, caſting that which is noiſome with a ſtrong contention out at the mouth. This is familiar to Nature, and the way which we alwayes deſire Nature ſhould take, for it is by places naturally commodious, & witneſſeth a ſtrong force and power of all the Faculties. And this is the proper *Criſis* of the *Empyici*, of thoſe that haue pluriſies and inflamations of the Lunges: and this is the beſt and the ſafeſt way. But if Nature be inſufficient to mooue this way, either by reaſon of the thickneſſe of the matter that yeeldeth not to the concuſsion of the Cheſt, or becauſe of the Muſcles. Then Nature is ſo wiſe and prouident that ſhe openeth another paſſage, findeth out ſome other way by which ſhe may eaſe her ſelfe both of the diſeaſe, and of the cauſe of it. Therefore, oftentimes ſhe purgeth this purulent matter by the Vrine, ſometimes by Apoſtemation, ſometimes but rarely ſhe emptieth it by the ſeidge.

The eaſieſt way.

The other 3. wayes.

By Vrine.

An inſtance. That it paſſeth away by the Vrine is prooued by daily experience, and euen now while I am writing theſe things, Nature hath found this very way in an olde Gentleman a Lawyer, who hauing had a Pleuriſie, and no meanes of blood letting or almoſt any other o

any moment, is beholding to Nature, who daily in great and notable abundance venteth this noisome humor by the Vrine. But beside experience, it may also be confirmed by the authority of very many as well of ancients as of later writers. *Hippocrates* and *Galen* are very plentifull witnesses of it: we will onely quote the places in them, and thither referre the Readers for his better satisfaction. *Hippocrates lib. 1. Epidem. sectione secunda*, twice in that section. *Lib. 3. Epidem. sect. 3. Galen lib. 6. de locis affectis. Cap. 4. Comment. ad Aphoris. 75. sec. 4.* We may add to these if it were needfull, *Auicen*, *Paulus*, *Mesues*, and many others.

By Seidge. Thirdly, this matter is purged by the Seidge, but *Hippocrates* saith, *It is very daungerous, yea mortall.* *Galen* in his Booke *de Coacis*, *It is no wonder* (saith he) *that Quitture or purulent matter should flow downe from the parts aboue the Midriffe into the belly, that is, into the guts.*

By Apostemation Fourthly, this matter is purged by Apostemation (Physitians call that *per abcessum*) either of the lower or vpper parts. *Hippocrates* saieth in *Porrhet*, *From a Peripneumonia or inflamation of the Lungs Apostumations do breede vnder the eares, or in the lower parts, and do there suppurate, and those men are deliuered from the disease.* And againe *in Coacis*, *Those Apostemations that descend vnto the Thighes in such as are troubled with the Peripneumonia, are all of them profitable.*

Which way is best. Thus many wayes therefore are numbred by *Hippocrates*, by which the purulent matter of the Chest is by Nature euacuated, first by the mouth, secondly by the kidnies, thirdly by the gut and lastly by Apostemation or abcesse. The first is safest, and therfore chiefely to be desired, next that which is by the Vrine, for it bringeth least labour or trauel to the frame of Nature, that is, to the due disposition of the bodie: onely it is troublesome, because it is painefull, as being accompanied with a Strangurie, yet not that continuall, but catching as it were and by turnes. That which is by the guts is the worst of all, for it breaketh or dissolueth the Faculties of the stomack, as well of Appetite as of Concoction, and of the guts also with his noysome stenche, and beside by this acrimony and ill-quality of the matter, causeth an incureable bloody Flix. But that euacuation which is by apostemation is profitable, if so be it fall into the lower parts, both because it is far remoued from the first diseased part, and also because that kinde of excretion is as the Physitians sayes, ἄξιος τῆς σωτηρίας, a conuenient kind of euacuation, and proportionable both to nature & to the disease. For a lawfull Apostemation ought neither to be ἡμίφορος nor ἀνάφορος, that is, neyther ought part of the matter flow to the place of Apostemation, but all; nor al take way vpward but downward, onely for to ascend is against the nature of the humor, and argueth alwaies a gadding quality therein.

The way of apostumation when good

By the womb. *Ariteus* in his booke *de Morbis Chronicis* addeth, that in women sometimes this purulent matter of the Chest commeth away by the womb. Thus we haue declared all the manners of Natures worke in the euacuation of noisome humors out of the cauity of the Chest, but by what wayes and passages Nature deriueth them as it belongeth to a higher contemplation. so will it be harder to know, and when it is knowne more profitable. The vpward expurgatiō by the sharp artery or wezon is manifest enough, for when the Chest is dilated the Lungs are blowne vp, & like a spunge sucketh vp the matter wherein they lie soked as it were in suds, & when the Chest is contracted the Lungs fall down and so thrust out the purulent matter togither with the smoaky excrements of the heart into the sharpe arteries, and they by continuity of passage into the wezon, and so it passeth to the mouth, and by coughing is excluded.

How the matter of the *Empyici* is purged

How it commeth vnto the Kidneyes. But by what waies it goeth to the kidnies & so to the bladder is greatly controuerted. *Erasistratus* would haue it go by the right ventricle of the hart, & so into the hollow vein, & thence by the emulgent into the kidnies. *It is sucked* (saith he) *first by the rare & spongie flesh of the lungs, then by the arterial vein, which is appointed for the norishment of the Lunges, & thence is deriued into the right ventricle of the heart; out of it into the hollow veine, from thence into the emulgents, thence into the vreters, & so into the bladder.*

Erasistratus his opinion. But this opinion of *Erasistratus* cannot be true, because nothing passeth out of the arterial vein into the right ventricle by reason of the membranes which are shut outward, & nothing goeth out of the heart by the hollow vein because of the three-forked membranes which shut inward.

Confuted. *Mesues* was of opinion, that this expurgation of purulent matter is by the veines, somtimes to the concauous part of the Liuer, & so by the seidge away, sometimes to the gibbous or conuex and so by the kidnies.

Mesues opinio *Fallopius* that oculate Anatomist, thinkes he found a neerer and more ready way, & for it describeth a small branch which runneth from the *Non-paril*, or *vena sine pari*, along by the ribs, and so piereeth the midriffe, & ioyneth it selfe with the fatty veine called *Adiposa* and the emulgent. This excretion of the *pus* or matter by the veines I do not altogither gainsay, yet I think it to bee a very vncouth way because their mouths opē not into the chest, neither are the veins stirred with any

any motion whereby they might ſucke ſo thicke and fœculent a matter, and that it ſhould ſweate through their coates is a very difficult matter and hard to be beleeued. Some there are which dreame of certaine ſecret *meatus* or pores for this expurgation, becauſe when men are aliue all paſſages yea euen ſubſtances are open, and the body perſpicable both within and without.

Strange paſſages which nature findeth.

True it is, that the body is ſo open; for we know (as ſaith *Hippocrates* in his 2. Booke *de Epidemijs*, and the 55. Aphoriſ. ſect. 7.) *That nature maketh way for Apoſtumations, euen through the bones*; the dropſie water paſſeth out of the capacity of the *abdomen* into the guts and ſometimes into the wayes of the vrine, the vrine is tranſcolated through the fleſh of the kidneis, the ſeed through the ſubſtance of the teſticles, the flegmatick humors of the ioynts ſometimes are drawne into the guts, ſometimes in a ſlimy ſpittle they are auoided out of the mouth by vnctions of quick-ſiluer. All theſe things I ſay we admit, but why ſhould we ſeek ſuch inſenſible paſſages for this expurgation of purulent matter, when ther be many very patent and eaſie to be perceiued? But what are they? Let vs heare *Galen* chalking them out vnto vs, in his 4. chap. and 6. Book *de locis affect. is. This queſtion* (ſaith he) *doth not a little trouble Eraſiſtratus followers, who thinke that there is nothing contained in the arteries but onely ſpirits; but to vs it is of no difficulty, becauſe we vnderſtand that the venall artery of the Lungs can leade ſo much of the purulent matter of an impoſtumation as it receiueth into the left ventricle of the heart, to be thence conueyed into the kidneyes by the great Artery.* His meaning therefore is, that the ſubſtance of the Lungs doth ſucke vp the *pus* or matter and deliuer it vnto the venall artery, that, vnto the left ventricle of the heart, the heart vnto the trunke of the great artery, and that, vnto the kidneyes and ſo to the bladder by the vreters. And before *Galens* time *Diocles* acknowledged the ſame way of expurgation.

Anſwere to the obiections

What the paſſages are.

Obiections.

But let vs heare now the exclamations of ſome new Writers againſt *Galen*. How may it be (ſay they) that ſo noyſome purulent and mattery a humour can be purged through the left ventricle of the heart, the ſhop and worke-houſe of the vitall ſpirits, and through the arteries the ſtore-houſes of the ſame ſpirits, without great danger vnto the patient? Shal not the ſpirits which of their owne nature are moſt pure, be infected and tainted in that medley? For if but a malignant vapor or poyſonous ayre do breathe from a bone, or any veſſel vp vnto the heart, ſtraight we are ouertaken with a fainting or ſwounding. Why therfore ſhall not an vnſauory and noyſome quitture or *pus* gotten into the very heart it ſelfe do at leaſt ſo much? But we know nature to be ſo wiſe and prouident that ſhee vſeth not to moue her excretions but by wayes that are ſafe and of auaile: now who will call the heart and the arteries places ſafe or conducible to lead away ſuch fœculencies? Theſe and ſuch like obiections they make who do not allow of the paſſages aſsigned by *Galen*. But they do not remember that it is one thing for a thing to be done critically, and another thing to be done ſymptomatically; one thing to be done by force & contention of Nature, another by the force and contumacy of the malady; one thing to be done by a faculty, another thing by a diſeaſe: and finally, one thing by a ſtrong and vigorous, another thing by a weake and feeble faculty.

Anſwere to them.

If this transfuſion of the purulent matter be criticall and the ſpirits ſtrong, then is this paſſage by the heart without any damage to the patient; for nature retaineth and preſerueth the ſpirits and auoydeth onely that which is hurtfull. But if the ſtrength be feeble, then doth the patient dye in the very expurgation; and if you cut him vp when hee is dead, you ſhall finde the left ventricle of the heart ful of purulent matter; which deceiueth many vnskilfull people, who cry out that his heart was apoſtumated.

A miſtaking of an apoſtumation of the heart.

Finally, beſide the authority of *Galen*, in his Commentary *In Coacas prænotiones*, and Anatomicall demonſtration, I will adde for confirmation of this poynt two Hiſtories. The firſt *Hollerius* reporteth where hee treateth of the heate of the vrine. A certeine woman (ſayth he) with intolerable torment did make a purulent water, after the fourth month ſhe dyed and was opened: there were found in her heart two ſtones, with many ſmall Apoſtumations, the Kidneyes and all the wayes of the vrine being ſound. Wherefore this purulent matter was purged by the great artery.

Two Hiſtories *Hollerius*.

Laurentius.

Of the other Hiſtory *Laurentius*, one of our truſty guides in this trauell, is a witneſſe. An honeſt Citizen of *Mompelier* in *France* was ſicke or indiſpoſed with a hypochondriake melancholy for 3. yeares, and the diſeaſe was ſharpe: at length an acute Ague ouertooke him and he dyed, but a whole month before his death twice in a day lightly hee was troubled with a light ſwounding or fainting with ſome little heate of his vrine, and an incredible

dible deſire of making water, but after he had auoyded a thin, red and ſtinking vrine, hee came preſently againe to himſelfe.

After he was dead and opened, we found the whole cauity almoſt of his cheſt filled with that thinne, red and abhominably ſented humour, and the like wee found alſo the left ventricle of his heart to be full of, which, ſayth *Laurentius*, when I ſaw and wondred at, preſently the place in *Galen* before quoted came into my minde, and in the preſence of ſome maiſters in Chirurgery and many young ſtudients in phiſicke, I opened, that the cauſe of his frequent defections and vnconſtant ſtrangury was to bee referred to the tranſfuſion of the virulent matter through the left ventricle of the heart and the arteries; which my opinion they all applauded; becauſe the humour contayned in the cheſt and the vrine that hee auoyded in his defections or ſwounds were both of a colour, ſubſtance and ſauour. And thus much to redeeme *Galen* from the vniuſt imputation layd vppon him by ſome, otherwiſe not vnlearned, but in this not ſo conſiderate as I thinke they ought to haue been.

QVEST. VIII. *Of the Temperament, nouriſhment, Subſtance and Fleſh of the Heart.*

CONcerning the Temperament of the heart, the Phyſicians are at great ſtrife among themſelues. *Auerrhoes* was of opinion, that the heart of his owne nature was cold, becauſe his greateſt part conſiſteth of ſuch things as are naturally cold, as immooouable fibres, foure great veſſelles which are ſpermaticall parts and without bloud and cold; and that it is hot by accident onely, by reaſon of the hot bloud and ſpirits contained in it and his perpetuall motion. Of the temperament of the heart.

This opinion of *Auerrohes* his followers ſtrengthen with theſe reaſons. Firſt, becauſe the fleſh of the heart is thight and ſolide, and nouriſhed with ſolide, thicke and cold bloud. Secondly, becauſe at the Baſis of the heart which is his nobleſt part, there groweth a great quantity of fat, whoſe efficient cauſe (ſaith *Galen*) is cold. Laſtly, becauſe it is the ſtore-houſe of bloud; now bloud (ſaith *Hippocrates* in his Booke *de Corde*,) *is naturally cold, for aſſone as it is out of the veines it caketh.* But to the firſt argument we anſwere, that the fibres and the veſſels are not the chiefe parts of the heart, but the fleſh: and therefore *Ariſtotle* and *Galen* call it a fleſhy *viſcus* or bowell. To the ſecond, that the fat groweth not in the ventricles, nor about the fleſh of the heart, but onely about his Membrane which in reſpect of his fleſh is but a cold part: beſide Natures finall cauſe; that was to keepe the heart from torrifying, ouercame all the reſt, which thing in nature is not vnuſuall. To the third we anſwere, that there are two ſorts of blood, one venall and another arteriall; the veniall indeed is leſſe hot but the arteriall bloud is exceeding hot. Now the hart is the ſhop or worke-houſe of arteriall not of venall bloud. *Auerrhoes* that the heart is cold. The 1. reaſon. The ſecond. The third. Anſwere to the firſt. To the ſecond To the third.

We conclude therefore that the heart is not onely hot, but of all the bowels the hotteſt, which we are able to prooue by authorities, reaſons, and experience. *Hippocrates de principijs* ſaith, *There is much heate in the heart, as being of all members the hotteſt*. *Galen* in the laſt chapter of his firſt booke *de temperamentis*. *The bloud receiueth his heate from the heart, for that of a' the bowels is by nature the hotteſt*. The reaſon is, The hart is the fountaine of heat & of the Nectar of life: it ingendereth the arteriall blood, the venall it attenuateth for the Lungs; heere the vitall ſpirits the hotteſt of all others are made. Finally, heere is the hearth & the fire wherby the natural heate of al the parts is refreſhed. Experience alſo. For if you put your finger into the hart of a beaſt ſuddenly opened, the heat of it wil euen burn as *Galen* ſaith in his firſt booke *de ſemine*, and experience proueth. Againe, the fleſh of the heart is the moſt ſolid of all fleſh, becauſe it is ingendered of moſt hot bloud, made denſe and thicke by the parching power of an exceeding great heate. But ſome will ſay that the ſpirits are hotter then the heart: I anſwere, it is true that in the ſpirits there is a greater heat, but in the heart there is more heate, more ſharpe and which heateth more, becauſe of the denſity of his ſubſtance; ſo fire in ſtraw or ſtubble though it be a flame burneth but lightly, for you may draw your hand through it without any great offence; but hot glowing yron although it haue not the ſame degree of heate that the flame hath, yet it burneth more ſtrongly and cannot be touched without danger. But it may be demanded, if the ſpirits be hotter then the heart and are bred in the heart, whence haue they that greater heat? I anſwere, The heart conſiſteth of three parts as it were or ſubſtances; a ſpirituall, a moyſt and a ſolid. The ſpirits are ingendered of the ſpirituall and hotteſt part of the heart, and are hotter indeed then the whole heart, but not hotter then that part that ingendereth the ſpirits. That the hart is hot. Authorities. Reaſons. Experience. How the ſpirits are hotter then the heart by which they are made. Compariſon. Whence the ſpirits haue their heate that is hotter then the hart is. Three ſubſtances of the heart.

rits. That this may be, *Galen* giueth an inſtance in milke: milke in his whole ſubſtance is either cold or temperate, but his fatty and buttery part is hotter then the whole body of the milke; ſo the heart is hot in his whole ſubſtance, but the ſpirituall part of the heart is hotter then the whole heart, and from that part haue the ſpirits their intenſe heat: & thus much of the actiue qualities of the heart. Now for the paſsiue there is as great diſſention. *Auicen de Temperamentis*, and *Galen* in his ſecond Booke *de Temper. Cap.* 3. and 12. and in his 3. Booke *de Aliment. facultatibus* ſay it is dry, and his fleſh hard and ſolid; now it is a ſure rule *That whatſoeuer is hard to feele too in a liuing body, that alſo is dry.* On the other ſide *Auerrhoes* will haue it moyſt, becauſe life conſiſteth in heate and moyſture, but the heart is the beginning of life and the ſhop of moyſture. *Galen* in the laſt Chapter of his firſt Booke *de Temperamentis*, calleth it a Bloudy Bowel, therefore moyſt; and in the ſame Chapter, *It is a little leſſe dry then the skinne*, therefore moyſter then the skinne. I anſwere, it is true that the heart is moyſter to feele too then the skinne. But *Galen* when hee ſayeth it is drie, compareth it not to the skinne but to the other parts, for ſo his words are. *The fleſh of the heart is ſo much dryer then the fleſh of the ſpleen or kidneyes, as it is harder*: And ſo much of the Temperament of the heart.

Whether the hart be moyſt or dry.

An axiome.

Reſolution.

How the hart is nouriſhed.

Concerning his nouriſhment, *Galen* in his firſt Booke *de vſu partium*, and the 7. *de Adminiſt. Anatomicis*, ſayeth it is nouriſhed with venall and thicke bloud; many of the later writers ſay it is nouriſhed with the thin bloud contayned in his ventricles. On *Galens* ſide, that is on the trueths, are theſe reaſons. It is a Catholicke principle, *Euery thing is preſerued and refreſhed with his like.* The fleſh of the heart is hard, thicke and ſolid, ſuch therfore muſt be his nouriſhment: beſide there is a notable veine called *Coronaria* or the Crowne veine, which compaſſeth a round the Baſis of the heart and ſendeth foorth branches into all his ſubſtance; but Nature vſeth not to doe any thing raſhly or in vaine, it ſerueth therefore for his nouriſhment: beſide occular inſpection prooueth it which no reaſon can conuince.

An axiome.

An argument from ocular inſpection.

The braunches of the coronarie veine are more and more conſpicuous on the left ſide of the heart then on the right, becauſe the thicker part wanteth the more nouriſhment. But the aduerſaries ſay that the outward part is onely nouriſhed with this veine, the inward with the bloud contayned in the ventricles: for ſay they, this veine is too little to nouriſh the whole heart being a very hot member and in perpetuall motion; beſide the veine looſeth it ſelfe in the *ſuperficies* of the heart and paſſeth not into the ventricles. But for the narrownes of the veine I cannot perceiue it is ſo ſmall as they talke of it; and for this motion it is true, yet there are many things that temper it, on the outſide it is couered almoſt with fat and compaſſed with a watery humour, and within it hath aboundant moyſture whereby though it be not nouriſhed yet is it watered and kept from drying and flaming; as boyling hot water keeps a veſſell on the fire from burning. And whereas they ſay the branches of the coronary veine paſſe not into the ventricles; I anſwere, that neither are the veſſelles diſperſed into the inner ſubſtance of the muſcles and the bones. *Hippocrates* ſayeth *That fleſh draweth from the next veſſels.* If you would faine reconcile the newe writers to *Galen*, you may ſay. That haply the inward parts of the heart are nouriſhed with the bloud contayned in the ventricles but not yet attenuated, for why ſhould the inward parts be nouriſhed with rarified bloud and the outward with craſſe and thicke; ſeeing the nature of the inward fleſh and outward is all one? and ſo much of the nouriſhment of the heart.

Arguments for the other ſide.

Anſwered.

A reconciliation.

Of the ſubſtance of the heart.

Whether it be a muſcle.

Nowe for the ſubſtance and fleſh of it, ſome ſay it is muſculous, but that we haue anſwered before in the deſcription; briefly thus. *Hippocrates* in his Booke *de Corde* calleth it a ſtrong muſcle: againe it is moued by a locall motion and ſo are none of the other bowels, as the Liuer, the Spleene, the Kidneyes, &c. but all muſcles are ſo moued. Moreouer, the fleſh of the bowels is ſimple and ſimilar, but the fleſh of the heart not ſo but wouen with threds and fibres like that of the muſcles, therefore it is a muſcle. *Galen* on the contrary will haue it no muſcle, for that muſcles haue ſimple fibres but the heart manifold, the muſcles haue but one and that a ſimple motion, for they bow or ſtreatch forth, lift vp or pull downe; but the heart hath diuers yea contrary motions: and this is a very powerfull argument which yet ſome ſeeke to ouerthow: becauſe ſay they there be many muſcles which haue diuers kinds of fibres, and alſo diuers yea and contrary motions; as the *Pectorall* muſcle which hath diuers fibres: and moueth the arme not vpward and downward onely but forward; alſo and the muſcle called *Trapeſius* which moueth the ſhoulder blade not only vpward and downward but backward alſo; and therefore the variety of his fibres and the diuerſity of his mo-

Tharit is.

That it is not.

Anſwere of ſome to *Galens* argument.

tions

tions do not exempt him from the number of muſcles.

Anſwere for *Galen*

I anſwere for *Galen*. Thoſe two Muſcles aboue named haue indeed diuers motions but not from the ſame part; but from diuers parts of the muſcles; for they haue diuers originals or beginnings. The *Trapeſius* ariſeth from the *back-part* or nowle of the head & from the rack-bones of the backe; by the former part it moueth vpward, and downeward by the latter. The *pectorall* alſo hath diuers beginnings, for it ariſeth from the *Throte* and from the whole breaſt-bone; wherefore theſe muſcles doe not pull downe with the ſame part wherewith they lift vp, but the heart is dilated and contracted in the ſame part; there is not therefore a like reaſon of their motions. The like may be ſaid of their fibres; for the fibres of thoſe aboue-named muſcles though they be of more kinds thē one yet are they diſtinct; the fibres of the heart are wouen together and confounded that no art or induſtry wil part them. The fibres of the muſcles are diuers in their diuers parts, but thoſe of the heart are all in euery ſmall part of the heart.

Auicen for *Galen* one weake argument.

Another ſtronger.

Moreouer, the taſte of the heart and of the muſcles is not one ſaith *Galen* in the 8. chapter of his 7. booke *de Adminiſtrat Anatom.*, *Auicen* ſaith the muſcles are weary the heart neuer: yet this ſeemeth to be no ſound reaſon, becauſe the midriffe which is a very ſtrong muſcle mooueth perpetually: but *Auicen* hath another reaſon for *Galens* opinion of more force which is this. The heart is no muſcle becauſe his motion is not voluntary, for we can neither forſlow nor haſten, neither ſtay nor ſtirre vp his motion as we may the motion of the midriffe and of all the other muſcles. We conclude therefore with *Galen* that the heart is no muſcle, but either an affuſion of bloud which *Eraſiſtratus* called *parenchyma*; or ſome peculiar fleſh. How *Hippocrates* is to be vnderſtood wee haue ſaid before, to wit, abuſiuely; it is muſculous becauſe it is red & fibrous, but not a muſcle. But it will be obiected it is moued with locall motions, therefore it is a muſcle.

The concluſion with *Galen*.

Anſwere to *Hippocrates* authority.

To the firſt reaſon.

I anſwere, that by the ſame reaſon ſhould the wombe be a muſcle, for we haue ſhewed how that is moued euen locally ſometimes, as when it cloſeth in conception, or is dilated in the birth: and the guts haue a locall motion called *motus periſtalticus* which no man will ſay is a voluntary motion or that therefore they are muſcles.

To the ſecond.

To the other argument we ſay, that the fleſh of the heart though it bee fibrous yet it is ſimple, becauſe the fibres are of the ſame ſubſtance with the fleſh of it as the fibres of the ſtomacke, the wombe and the guts; but the fibres of the muſcles are particles of Nerues and Tendons much vnlike their fleſh: and this indeed is *Galens* anſwere in his 2. booke *de temperamentis*; yet we affirme that the fibres of the heart are ſtronger and harder then the reſt of his fleſh, which maketh it ſtronge and better able to indure his perpetuall labour.

Why the fleſh of the hart is fibrous

But why is the fleſh of the heart more fibrous then that of the Liuer or kidneyes. *Galen* anſweres, *The fibres of the heart are made for neceſſary vſes of traction retention and expulſion, by the right it draweth in the Diaſtole or dilatation, by the oblique it retaineth, and by the tranſuerſe it expelleth in the* Syſtole *or Contraction.*

QVEST. IX. *Whether the heart will beare an apoſtumation, ſolution of continuity or any grieuous diſeaſe.*

Authorities that the heart will not beare a diſeaſe. *Hippocrates.* *Ariſtotle.* *Aphrod. ſeus.* *Paulus Aegineta.* *Pliny.*

THE laſt quæſtion concerning the heart ſhalbe whether it will beare any notable diſeaſe or no. *Hippocrates* ſaith, (in his booke *de morbis.*) *The heart is ſo ſolid and denſe that it is not offended with any humour*, and therefore it cannot be tainted with any diſeaſe. *Ariſtotle. The heart can beare no heauy or greeuous diſeaſe becauſe it is the originall of life. Aphrodiſæus. In the heart can no diſeaſe conſiſt, for the patient will dye before the diſeaſe appeare. Paulus. Any diſeaſe of the heart bringeth death head-long vpon a man. Pliny. Onely this of all the bowels is not wearied with diſeaſes, neyther indureth it the greeuous puniſhments of this life; and if it chance to bee offended preſent death inſueth.* Yet how repugnant this is to experience many Hiſtories doe beare witneſſe. *Galen* (in his 2. Booke *de placitis*) reporteth that a ſacrificed Beaſt did walke after his heart was out, and in his 7. Booke *de Adminiſtra. Anatom.* he maketh mention of one *Marullus* the ſonne of a maker of Enterludes, who liued after his heart was laide bare euen from the purſſe or *pericardium*, and (in his 4. booke *de locis affectis*) if a man be wounded in the heart and the wound pierce not into the ventricles but ſtay in the fleſh, he may liue a day and a night. *Beneuenius* writeth that he hath ſeene many Apoſtemations in the heart. We told you a ſtory euen now out of *Hollerius* of a woman who had two ſtones and many Apoſtemations found in her heart.

Manifold Hiſtories prouing the contrary.

Matthias

Mathias Cornax Physitian to the Emperor *Maximilian* saith, that he dissected a Bookseller, and found his heart more then halfe rotted away. *Thomas a Veiga* writeth, that there was a red Deere found, in whose heart was sticking an olde peece of an Arrow wherewith he had beene long before wounded in hunting. But you shall reconcile these together, if you say the heart will beare all afflictions, but not long; or that it is subiect to all kinds of diseases, but will beare none greeuous. For example, the heart will suffer all kindes of distemper, but if any distemper be immoderate or notable the party presently dies, so sayeth *Galen* in his fift Booke *de locis affectis*, *Death followes the immoderate distemper of the Heart*, When *Galen* saith, in the fifte Chapter of his first Booke *De Locis Affectis*. That the heart will beare no Apostemations, hee vnderstandeth such an Apostemation as comes by the permutation of an inflamation. For the Creature will die before the inflamation will suppurate or grow to quitture. Say that the Apostemations found by *Beniuenius*, *Hollerius* and *Mathew Cornace* were Flegmaticke; or say, that rare things do not belong to Art; or with *Auerrhoes*; as in Nature so in diseases wee oftentimes finde Monsters. That a creature can walke and cry when his heart is out I beleeue well so long as the spirits last in his body which it receiued from the heart, when they faile hee presently dieth.

How these are to be reconciled.

Galen interpreted.

Answeres to the examples

Andreas Laurentius maketh mention of a strange accident which happened in the Court of *France*. *Guichardine* a Noble Knight and Ambassador for the Duke of *Florence* beeing in good health and walking with other Noble-men, and talking not seriously but at random, presently fell stone dead neuer breathing and his pulse neuer mooving. Manie tolde the King, some saide he was dead, some that hee was but falne into an Apoplexie or a Falling sickenesse and that there was hope of his recouery; The King (saith *Laurentius*) commanded me to take care of him; when I came, I found the man starke dead, and auouched that the fault was not in his braine but in his heart. The next day his bodye was opened, and we found his heart so swelled that it tooke vp almost all his Chest; when wee opened the Ventricles, there yssued out three or foure pound of blood, and the orifice of the great Veine was broken, and all the forked Membranes torne, but the Orifice of the great Artery was so dilated that a man might haue thrust in his arme So that I imagine, that all the Flood-gates being loosened, so great a quantity of bloode yssued into the Ventricles that there was no roome for the dilatation or contraction, whereupon hee fell suddenlie dead; yet is it a great wonder how without any outward cause of a stroke, or fall, or vociferation, or anger, so great a vessell should be broken. It may be he was poisoned, for the Italians they say are wondrous cunning in that Art, & in the Contention of Nature that dilaceration hapned.

A strange story of a *Florentine* Ambassador in the Court of France.

QVEST. X. *Of the nature of Respiration, and what are the Causes of it.*

AND thus much of the proper motion of the Heart, what causes it hath, what manner motion it is, what power or faculty mooueth the Arteries, when and as the heart is mooued; or after and otherwise: Howe and where the vitall spirites are generated and their immediate matter prepared, what is the temperament of the heart, how it is nourished, what his structure is & how many the parts are of his substance with their vse and functions: Finally, howe able to beare and endure affectes and diseases. The resolution of which questions, though they do not properly pertaine vnto Anatomy all of them, yet do they so depend one vpon another as it seemeth necessary that he that would know one should also know all; notwithstanding in our treating of them we haue verie often restrained our Discourse and conteyned it within such limites as are not farre distant from Dissection it selfe.

A briefe enumeration of the difficulties about the motion of the heart.

Of Spiration.

It remaineth now, that we shou'd a little stand vpon another motion in our bodies and the Instrument thereof which Nature hath ordained to be seruiceable to this motion of the heart, and that is Spiration or breathing. For the Heart being exceeding hot and therfore a part of great expence needed a continuall supply of nourishment for the spirites, and of ventilation for himselfe. For *Hippocrates* saith in his Booke *De Natura pueri*, *Calidũ omne frigido moderato Nutritur & fouetur*? That which is hot is nourished and cherished by that which is moderately colde: which sentence *Galen* in his Book *de vsu Respirationis* thus elegantly expoundeth; Euen as (saith he) a flame shut vp in a straite roome and not ventilated with the aer burnes dimmer and dimmer till it be extinguished, so our naturall heate if it want cold to temper it growes faint and wasteth away to vtter confusion. For it is like a flame mooued both waies, vpward downward, inward and outward; vpper and outward, because

Why necessary.

becauſe it is light as being of a fiery and aery nature; downward and inward in reſpect of his nouriſhment; either of theſe motions if they he hindred, the heate either decayeth or is extinguiſhed; it decayeth for want of nouriſhment becauſe it cannot be mooued downward and inward: It is ſtrangled and extinguiſhed when it cannot be mooued vpward and outward and ſo refrigerated.

Wherefore, the ſpiration or breathing of colde is verie neceſſary for the preſeruation of naturall heate; but what ſhall this cold be? Surely either aer or water: aer is more neceſſary in perfect and bloody creatures, firſt becauſe it ſooner followeth the diſtention of the breſt and ſo the dilatation of the Lunges, and filleth all that is dilated to keepe out vacuity; ſecondly it cooleth ſooner, as better diſtributing his partes into euery ſecret corner of the heart: finally, it is better expirated or breathed out then water; though it be not more eaſily drawne in. Aer then is the beſt cooler for the heart, and that muſt be brought vnto it by breathing: now this ſpiration or breathing is double, inſenſible and ſenſible; Inſenſible ſpiration *Hippocrates* and *Galen* cal properly διαπνοὴν, and the Latins *Perſpiration* & *Tranſpiration*. The other and ſenſible breathing is called ἀναπνοὴ, that is, *Reſpiration*. Tranſpiration is by the ſecret pores of the skin, Reſpiration by the mouth and the noſe. Thoſe creatures whoſe heate is weake and faint do liue onely by Reſpiration, ſo all that are without blood or which we cal *Inſecta* of certaine diuiſions they haue about their necks or bellies; ſo the infant in the womb tranſpireth onely but doth not reſpire; and many women in fits of the Mother (the naturall heate of their hearts being diſſolued by a poiſonous breth ariſing from putrified ſeede) do liue a while in trances onely by Tranſpiration. But thoſe creatures whoſe heate is neerer to the nature of flame, by tranſpiration onely cannot bee tempered. Wherefore ſuch heate needeth a farther helpe to waſte more aer vnto it, and that is done onely by reſpiration.

Whether aer or water is fitteſt to cool the heats.

Tranſpiration & Reſpiratiõ.

Fittes of the Mother.

This Reſpiration therefore hath two parts, Inſpiration and Expiration; Inſpiration is the drawing in of the aer, Expiration the breathing it out. Inſpiration is like the *Dyaſtole* of the heart, Expiration like the *Syſtole*.

The partes of Reſpiration.

This Reſpiration whether it be Naturall or Animal hath troubled the heads of Schollers a great while, and would alſo now trouble ours if we ſhold muſter together all the Reaſons which are brought on both ſides; yet becauſe the queſtion is worthy the deciſion wee will breefely as we can reſolue it with your patience. The argoments to prooue it not to bee Animall or voluntary are. Firſt becauſe voluntary actions are from election: but men aſleepe (when yet there is reſpiration) haue no election, no will, becauſe ſleepe is a reſt or ceſſation of all Animall actions. Hence it is that *Galen* calleth the *Caros* a ſleepie diſeaſe *Priuationem Animalitatis*, a priuation of al the animal Faculties; yet in that diſeaſe the Reſpiration is free: as likewiſe in the Apoplexie which is a reſolution or palſie of the whole body. Now where is no ſenſe remaining, can there then remaine any voluntary motion? yet we ſee Reſpiration remaineth.

Whether Naturall or Animal.

Not Animall.

The Reaſons.

Againe, to be voluntary and perpetual are contraries; for voluntarie actions do al breed wearineſſe, but Reſpiration breeds not wearineſſe in the motion, but if the motion be any whit checked or ſtayed, that ſtay or checke breeds wearineſſe: Finally when the Reſpiration is vitiated we apply remedies vnto the region of the heart not vnto the braine, which is the originall of voluntary motion. On the contrary, the great argument to prooue it to be voluntary is, that we can breath when we will, and when we will we can ſtay our breath: ſo as many haue thus voluntarily ended their dayes, I meane by ſtaying their owne breath. *Galen* in his ſecond Booke de *Motu Muſculorum* telleth of a Barbarian ſeruant, who beeing throughly angred purpoſed to lay violent hands vpon himſelfe, hee threw himſelfe therefore vpon the ground, and held his breath a long time remaining vnmooued, at length turning himſelfe a little he breathed out his life.

That it is Animall.

Hiſtories.

C. Licinius Macer a Pretorian Citizen of Rome, being accuſed for oppreſsion by exactions, whilſt the Iudges were giuing ſentence ſhut vp his owne mouth, and couering it with his Handkerchiefe reteyned his breath till he fell downe dead.

Coma the brother of one *Maximus* a Captaine of Out-lawes, when hee was asked concerning the ſtrength and enterpriſes of the Fugitiues, gathered his ſtrength together, couered his head, and falling vpon his knees held his breath till he dyed euen in the handes of thoſe that guarded him and before the face of the Iudges.

Cato Vticenſis, when his ſonne had taken away his ſword, he perſwaded his Seruants to giue it him againe, ſaying he would keepe it for his defence, not to murther himſelfe with.

For sayeth hee, *If I listed to die, I could easily hold my breath to serue that turne*: Besides *Hippocrates* sayth in his third Section of the second Booke *Epidemion*, that the cure of continuall yawning which Physitions cal *oscitation*, is long breathing: & *Aristophanes* in *Plato* his *Symposio*, being troubled with a hiccock, intreated *Eriximachus* the Physition to tell out his tale for him, *That wil I saith he, & in the meane time hold your breath some good while & your hiccock wil cease, and then you shall take my turne as I haue taken yours.* We may then reteyne our breath when and how long we will and therfore it is a voluntary action. For the instruments whereby wee breath are all Animall, as the *intercostall* muscles, the midriffe which is also a muscle, and the nerues. Finally, if the braine bee offended as in a phrensie, then is the Respiration offended.

How to cure yawnings & the hiccock.

Wee see here two opposite opinions, both which wee cannot maintaine vnlesse they will either of them remit somewhat and yeeld a little either to other, and then it will not be hard to reconcile them after this manner. Some actions are purely and simply Naturall, as Concoction, Nutrition &c. Some partly voluntary, as speech and walking. Some mixt, that is partly Naturall partly Animall, as the auoyding of water and excrements, as *Galen* sayth in the fourth Chapter of his 6. Booke *de locis affect*; and in the sixt Chapter of his second Booke *de motu musculorum* he likeneth Respiration to these. Respiration therefore is a mixt action, partly Natural and that in respect of the final cause and of necessity, partly Animall in respect of the instruments of it, the muscles.

A reconciliation of 2. aduerse opinions.

Respiration a mixt action.

2. instances.

Those that are strangled do not breath because they cannot Animally; the nerues and muscles being intercepted with the rope. *Hysterical* woemen that are troubled with the *mother* do not breath, because they cannot Naturally: for there is no vse of respiration, nor no necessity vrging it although the instruments bee at liberty; and Nature hath here very wisely ordayned that although this action were absolutely necessary and so naturall for the preseruation of life; yet there should also be in it some commaund of the will, because it is often very profitable to stay the breath and often to thrust it out with extraordinarie violence.

Why it was necessary that respiration should be partly voluntary.

If wee be to giue very diligent eare to any thing, if to passe through any vnsauoury or noysome places, if we fall or be throwne into the water, it is very necessary that we should bee able to conteyne our breath: on the contrary, to blow vp any thing, to winde a horne or sound a trūpet, to blow the fire or such like; it is very profitable that we should be able to breath with extraordinary violence. Now in a word we will satisfie the arguments on both sides; and to the first in the first place.

They say that men Respire when they sleep, but in sleepe there is no vse of election or will. I answere there is a double will, as *Scaliger* sayeth, *One from election proper to men and men awake, the other from instinct and this is in men a sleepe and in bruite beasts.* The motion of respiration when we sleepe is by instinct, neither are all the Animall faculties idle in sleepe, or extinguished in those diseases before named; but in sleep they are *remitted* as *Galen* sayth not *intermitted*; for euen the muscles haue a motion which we call *Tonicum motum A rigid motion*, especially the two sphincter muscles, and in the diseases they are depraued.

Wil is double

Motus Tonicus

The reason why we are not wearied with continuall respiration, is because there is continual vse and necessity of it, although it cannot be denied that euen respiration being constrayned wearieth the creature much.

On the contrary, they that affirme this respiration to bee meerely voluntary, alleadge that we are able to stay it when we will and to moue it when wee will; to which I answere. That is properly and absolutely a voluntary action which may bee stayed at our pleasure when it is doing, and againe done when it is stayed; but respiration is no such action: for if the Respiration be altogether stayed, as in those whose histories are aboue mentioned, then is the creatures life extinguished and the respiration cannot againe bee mooued. And for the two other arguments that respiration is by Animall instruments, & that in a phrensie which is a disease of the brayne, the respiration is vitiated. I answere, that they proue indeed that in respiration there is somewhat voluntary, but they doe not proue that there is nothing naturall. We therefore do determine that Respiration is a mixt action, and to it do concurre both principles ioyned together the Brayn and the Heart, the Animall and the Naturall faculties.

The determination.

To conclude this Chapter and discourse of Respiration: The pulse and respiration we see are two distinct motions, yet so neare of kinne as men doe not ordinarily obserue the diffe-

differences betweene them: wee will therefore in a word tell you wherein they differ and wherein they agree.

They agree in that that they both ſerue one faculty that is the Vitall; for they were both ordained onely for the heart which is the ſeate of the vitall faculty. Moreouer, they haue both one finall cauſe a threefould neceſsity; of nutrition, temperation and expurgation: nouriſhment of the ſpirits, tempering of the heate and purging of ſmoky vapours. Thirdly, they agree in the condition of their motions, for both of them conſiſt of a *Syſtole* and a *Diaſtole*, and a double *reſt* betweene them: but in theſe things they differ. That the pulſe is a Naturall motion, continuall not interrupted, and without all power of the will. Reſpiration is free, and ceaſeth ſome whiles at our pleaſure; the efficient cauſe of the pulſe is only Nature, of Reſpiration Nature and the Soule together; the inſtruments of the pulſe are the heart and the arteries, of Reſpiration the muſcles: the pulſe is from the heart, Reſpiration not from the heart but for the heart. Finally, the heart beateth fiue times for one motion of Reſpiration.

Whether is more noble and neceſſary the pulſe or reſpiration.

Laſtly, whether is the pulſe or Reſpiration more neceſſary or more noble? More noble ſurely is the pulſe, becauſe his inſtrument the heart is more noble, his effect the vitall ſpirit is more noble then the ayre; and the end is better then that which ſerueth for the end: but Reſpiration was made for the preſeruation of the pulſe: but nowe for their neceſsity there needeth a diſtinction. There is one pulſe of the heart and another of the arteries; the pulſe of the heart is more neceſſary for life then Reſpirution, but the particular pulſation of the arteries is leſſe neceſſary then Reſpiration; for though the arteries bee bound or intercepted the creature dyeth not preſently, but if the Reſpiration be ſtopped hee is preſently extinguiſhed.

QVEST. XI. *Of the Temperament and motion of the Lungs.*

Of what temper the lungs are.

That they are cold.

Reaſons.

ONcerning the Temperament of the Lungs, there is queſtion among the Maſters of our Art. Some hold them in the actiue qualities to bee cold, others to be hot. Thoſe that would haue them cold giue theſe reaſons for their aſſertion.

Firſt, becauſe their whole frame and ſtructure conſiſteth of ſpermaticall that is cold parts: theſe are, the griſtly artery, the arteriall veine, and the venall artery.

Secondly, becauſe they are made to refrigerate the heart, wherefore they are called the *Fanne of the heart.*

Thirdly, becauſe they are ſubiect to colde diſeaſes, as obſtructions, ſhortnes of winde, difficulty of breathing, and knottines called *Tubercula.*

Fourthly, becauſe they abound with flegmaticke and cold humors, which is diſcerned by that we cough vp.

Authority.

Laſtly, they alleadge an authoritie and a reaſon out of *Hippocrates*, the authority, for that he ſayth, *The Lungs are of their owne nature cold, and are farther cooled by inſpiration.* *Hippocrates* ground out of which they draw this argument is where hee ſayeth in his Booke *de Alimentis*, *The Lungs do draw a nouriſhment contrary to their body, whereas al other parts draw that which is like to them.* From whence they reaſon thus. The Lungs draw vnto themſelues blood attenuated in the right ventricle of the heart and are therewith nouriſhed. That bloud being very hot, their ſubſtance (if *Hippocrates* ſayd true, who is ſayde neuer to haue deceiued any man, nor neuer to haue beene deceiued himſelfe) muſt needes bee cold. But theſe arguments may thus bee anſwered.

A reaſon drawne from *Hippocrates.*

Anſwere to the argumens.

To the firſt, the veſſels are not the ſubſtance of the Lungs but the fleſh; which is made of a hot and frothy bloud.

To the ſecond, that they refrigerate and coole the heart not by their owne Temperament, but becauſe they drawe and containe outward ayre, which is alwaies colder then the heart though it be neuer ſo ſoultry hot.

To the 3. that their veſſels becauſe they are many and diuerſly implicated are ſubiect to obſtructiõs, but their fleſh which is their true ſubſtãce is ſubiect to inflamations & hot affects.

Whence the phlegme commeth that we cough vp.

How it becommeth white.

To the fourth, that the aboundance of flegme which we cough vp, is not generated by the natiue temper of the Lungs but falleth continually from the head which is the receptacle of cold excrements into the Lungs, ſo ſaith *Hippocrates*, *Many Catarrhes or Rheumes fall into the vpper venter*, that is the Cheſt. The lower part alſo as the ſtomack and the *hypochondria* do ſend vp plentiful vapors which the Lungs with this continuall motion do mixe with the foreſaid humor & thence commeth the whitnes. And as for *Hippocrates* authority

it may bee answered that hee compareth the temper of the Lungs with the temper of the heart and then indeed they are cold, as also the aer of a hot-house is cold in respect of the heart.

Hippocrates expounded & retorted.

In the other place we say that *Hippocrates* speaketh of the aer inspirated or breathed in, not of bloud; and so that place proueth that the Lungs are hot rather then cold, because they draw aer which is cold and contrary to their body which is hot. But the truth is, that the contrariety he speaketh of in that place is rather a contrariety of motion; as if hee should say, other parts draw a nourishment like vnto themselues frō an inward store-house which is the Liuer into the very vtmost parts of the body; but contrariwise the Lungs draw the nourishment of the spirits, that is, the aer by the outward parts, that is, the nose and the mouth into the inward, that is, the heart. Although I am not ignorant that *Galen* interpreteth those words otherwise which shall not be necessary to make mention of in this place.

That the lungs are hot. 3. arguments.

It seemeth therefore that the Lungs are not cold; which yet will better appeare if wee can proue them to be hot. Three arguments we will be contented with; one from their substance, another from their nourishment, and a third from their vse. Their substance is fleshy soft & spongy, made as it were of the froth that ariseth of the hot bloud in the boyling; therefore not cold. Againe, they are nourished with thin bloud heated and attenuated in the right ventricle of the heart, which seemeth to haue beene made especially for the Lungs sake. Lastly, their vse is to prepare aer for the generation of the vitall, that is, the hottest spirit; they must therefore be hot. Thus Physitions reason on either side. I will onely heere put a doubt, reseruing the determination to another place.

A notable doubt put.

The Rheume falleth out of the head, part into the Lungs and part into the stomacke; Nature in both places worketh vpon it. The stomacke boyleth it againe, attenuateth it if it be thick, and of some part of it maketh good bloud; the rest it auoydeth into the guttes where another vse is made of it; and if the heate of the stomacke be languide and weake so that it cannot sufficiently mitigate it, we then helpe Nature.

Why the Rheume must be thickened before it bee coughed vp. Whence dry coughes cōe.

The Lungs quite contrary do thicken that part which falleth into them and that necessarily, for else it could neuer he auoyded; for it must be a solid body that the aer must lift vp before it in our coughing, because there is no passage for it downward appointed by Nature; and therefore it is, that thinne and subtle Rheume maketh a dry cough because the aer is not able to intercept it, but it trickleth downe the sides of the weazon still prouoking vs to cough, but in vaine because it hath not a compacted body which the aer might intercept till by time it be ripened, that is, grow thicke and then it is brought vp; or if of it selfe it do not thicken we thicken it by Art. Wee may therefore iustly wonder at this contrary worke of Nature; surely coldnesse in the Lungs can not thicken it, it being so neere to the fountaine of heate nor the ayer which is the moistest of al Elements cannot dry it: besides that, the Lungs are of themselues very moist as we shall prooue by and by. Againe, if heate in the Lungs do thicken it, why should it not thicken it also in the stomacke; but we see that cold stomacks doe onely make thicke and viscid flegme.

A mystery of Nature.

Truely heereunder lyeth a great mystery worthy of another place to be discussed in, to which therefore we will referre it and proceede to the second qualities of the Lungs, and enquire whether they be moist or dry. It may seeme they are dry, because their passages doe alwayes remaine open and neuer fall together, which is an argument of their hardnes and drynesse. Againe, *Galen* saith (in his 4. booke *de vsu partium*) they are nourished with chollericke bloud, but chollericke bloud is dry. Lastly, *Hippocrates* saith the Lungs are the seate of drought; for he appointeth two places of drought, the stomack & the Lungs. Concerning which, is that notable edict of *Hippocrates* (in *Epidemijs.*) The way to appease and satisfie thirst is to drinke cold water and to breathe in cold aer. These arguments we will first answere before we determine the contrary.

That the lungs are dry Arguments

Answered

To the first we answere, that if the opennes of their passages argue their drinesse, then should the braine also be dry whose ventricles are alwayes open and do not fall together in the strongest concussions or motions of the head, as in sneezing and fits of the *Epilepsie* or falling sickenesse. As therefore the braine is harder in the ends of the ventricles thereof (in which respect Anatomists cal that part the Callous body as we shall heare heereafter): So the Lunge where it compasseth the vessell is somewhat harder: or say rather, that the thinnesse and hardnesse of the branches of the Sharpe and Rough Artery do hold it out & keep the passages in a kinde of distention.

To

To the second we answere, that *Galen* by bilious or Cholericke blood meaneth thin and attenuated blood laboured in the right ventricle of the heart, which no man will say is drie but rather abundantly moist, as being mingled with aer the moistest as we saide of all Elements. To the last we answere, that the Lungs indeede if they be torrified are the seate of drought, becausse they dry vp the moisture of the heart and the partes adioyning; but if they be naturally disposed they are no cause of drought. It remaineth therefore that the Lungs are not dry, and then they must needs be moist; which yet further to proone wee want not arguments beyond all exception. First, because they are soft; for as hardnesse is a sure note of drinesse so is softnesse of moisture, but the substance of the Lungs is soft and lax, of which the very touch is a sufficient witnesse. Besides *Galens* authority is plainely for it, where he saith in his 4. Booke *de vsu partium*, *The flesh of the Spleene is soft indeed & laxe, but nothing to the substance of the Lungs which is the softest, the looseſt and the lightest.*

Galen expounded.

Arguments to proue the Lungs moyst.

Auicen interposeth saying, *That the flesh of the Lungs is not soft of his owne nature but by accident or euent*, because they lie steeped & drunken as it were in the moisture which falleth from the head, therefore he saith they are *not soft but maddid*; which if it were so, then wold they be drier in those bodies that haue dry braines, and moreouer would in all other bodies become drier, as the moisture which falleth from the head is exhausted and dried vp, both which are contrary to all experience. We therefore conclude that the Lungs are naturally moist, and by so much moister then the liuer by how much they are softer. And thus much of the temperament of the Lungs, now followeth their motion. Concerning which I find three opinions; one of *Aristotles*, another of *Auerrhoes*, the third of *Galen* and the Physitians. *Aristotle* in the 6. chap. of his third booke *De Part. animalium* thinketh, that they haue the original of their motion from the heart on this manner.

Auicens conceite.

Confuted.

The determination. 3. Opinions. Aristotles.

The heate of the heart being encreased, with a kinde of violence lifteth vp the Lungs & then aer entreth for the auoiding of vacuity and emptinesse that infest enemy of nature; the colder aer setleth the boyling of the heate, as we see cold water beeing powred to boyling water setleth it; as therefore in the diffusion of the heate the Lungs are dilated, so the heat residing or setling they are contracted and the aer expressed or driuen out. *Auerrhoes* ioyneth so far with *Aristotle* that he thinketh the heate to be the author of Respiration, but he saith that the Lungs follow not the motion of the Chest, but are mooued by a proper and peculiar power of their owne, because else there should be a violent motion which shoulde be perpetuall, that which is vtterly against the rules of nature. True it is (saith he) that there is a wonderfull consent betweene the Chest and the Lungs, which is the cause that one of them cannot moone or rest but when the other mooueth or resteth, yet neither of them is cause or originall of the others motion. The third opinion is of *Galen* and the Physitians to which also we encline, who thinke the Lunges are not mooued by an inbred or proper power of their owne, for where are their Fibres and the strength of Filaments or strings for that purpose? Neither by the faculty of Pulsation which ariseth from the heart by which the arteries are mooued, & that because the motion of the Lungs somtimes doth intermit, sometimes is quicker and slower as we list: neither by the animall faculty because there be no Muscles: but we conceiue that the Lungs are mooued by an accidentary motion, as following the motion of the Chest to auoid vacuity. For when the Chest is distended the Lungs are filled with aer and enlarged, and when that is contracted they are emptied and fall. *Galen* establisheth this his opinion with this reason, because there is no disposition of the body found wherein the Lungs are mooued when the Chest remaineth immooueable: which thing Experience also confirmeth. For if the Chest be opened so as the aer may get in by the wound, the Lungs become immooueable; because the aer being gotten into the void and empty space taketh away the necessity of the motion of the Lungs which is to auoid vacuity as we haue saide: but if the Chest be sound, it is of necessity that it beeing distended the Lungs also should be dilated for auoyding of that vacuity. And whereas *Auerrhoes* obiecteth that there is no violent motion perpetual, and yet the motion of the lungs should be violent if it should follow the motion of the Chest. I answer, that the inference is very absurd, for euery motion is not violent which is mooued after anothers motion, for by that reason the bones also should be mooued with a violent motion. But why are not the Lungs wearied with their perpetuall motion? I aunswere, because they are almost insensible.

Auerrhoes.

Galens.

The Lunges not mooued by any proper power of their owne.

Not by the faculty of Pulsation.

Not by the Animal faculty.

But by accident or Consequence.

Galens reason.

Experience.

Answere to Auerrhoes.

Why the Lunges are neuer wearie.

QVEST. XII. *What kinde of motion the Cough is, and whether any part of the drinke fall into the Lungs.*

What parts are cauſes of coughing.

THat the Cough proceedeth from the affection of almoſt all the partes of the Cheſt, as the *Pleura*, the *Mediaſtinum*, the Lungs with their veſſels, the midriffe, and ſometimes of the *Intercoſtall* muſcles alſo, it is more then manifeſt; For in both the kindes of Pleuriſies, the true and the baſtard, the *Peripneumonia* or inflamation of the Lungs; the *Aſthma* or difficulty of breathing, the vlcer of the Lungs called *Pthoe*, the Dropſie wherein the Midriffe is preſſed vpward: in all theſe I ſay the Patient is troubled with a continuall Cough. But now to what faculty wee ſhould referre this coughing that is a great controuerſie. It may be thought it is Animall and voluntary, becauſe the Cough is nothing elſe but a ſtrong effliation or breathing forth. Now this effliation is done by the helpe of all the muſcles which contract the cheſt.

That the cough is frō the Animal faculty.

Galen alſo in his ſecond Booke *de cauſis ſymptomatum* ſpeaking of ſneezing coughing and vomiting, concludeth that vomiting is a ſymptome of the naturall faculty and coughing of the Animall. Others there be which thinke it to bee an action of the naturall faculty, becauſe it is a concuſsiue motion and is done by the endeuour of Nature, to exclude that which is offenſiue vnto her; now all Concuſsiue motions are Naturall. For all the partes of the body of their owne naturall conſtitution haue euery one their owne ξυσμὸς ſ. *Concuſſions* when they are ſhaken for the auoyding of any thing which offends them: ſuch is the concuſsion of the brain in ſternutation or ſneezing; of the ſtomacke in the hiccock, of the bladder in auoyding the ſtone, of the whole habite of the body and the fleſhy membrane in a rigor or ſhaking fit, and finally of the cheſt in coughing. Moreouer ſometimes we cough againſt our will, neither can we alwaies when we will forbeare it. Both theſe opinions may be reconciled, if as we ſaide earſt in reſpiration, ſo here in coughing, that it is a mixt action of an Animall and a Naturall.

That it is frō the Natural faculty.

The reconciliatiō of theſe two opinions.

The motion is Animall becauſe it is done by the helpe of muſcles, but the cauſe mooving the motion is Naturall; for a cough is not raiſed without the endeuor of the expelling faculty. But another queſtion may be asked here, whether the cough be a diſeaſe or an ordinary worke of Nature. *Galen* in his ſecond Booke *de ſymptomatum cauſis*, and in his fift *de locis affectis* ſeemeth to determine diuerſly; ſometimes that it is a worke of Nature, and ſometimes againe as in his Booke of *Trembling and Palpitation* that is againſt Nature: but we may well reconcile *Galen* with himſelfe if wee ſay, that in reſpect of the faculty whereby we cough it is a Naturall affection; for the beginning of the motion is from nature, that is from the expelling faculty; but in reſpect of the cauſe which mooueth the faculty as the rheume, the bearing vp of the midriffe or ſuch like, it is againſt Nature and a very diſeaſe; but ouer this cauſe the Naturall faculty hath a kind of power or command which it ſheweth in laboring thus to auoide it.

Whether to cough be a diſeaſe or no.

Galen reconciled to himſelfe.

To conclude both this Chapter and all our diſcourſe of the vitall parts, it is a queſtion whether the drinke we drinke goe into the Lungs or no. *Hippocrates* ſayeth in his Booke *de Corde* ſome part of it goeth that way, becauſe if you giue a Swine a drinke coloured with vermiliō or any ſuch like thing & preſently cut the throat, you ſhal perceiue the wezon colored with the drink, which is a certaine argument & demonſtratiue; alſo in the ſame place hee thinketh that the water which is found in the *heart purſe* is a portion of our drinke: againe Phyſitians in the fretting or exulceration of the weazon, and diſeaſes of the cheſt do appoynt the Patient to lie long vpon his backe and leaſurely to lick down their medicines, that ſo ſome of them may fall downe into the Lungs.

Whether the drink go into the Lungs.

Another demonſtration may be that the arteries haue more whey or vrine in them then the veines; whence ſhould this whay come? but that a part of the drinke and more liquid nouriſhment doth ſlip downe by the weazon into the Lungs and ſo into the arteries, and from them by the emulgent arteries into the kidneyes to bee auoided by the bladder: for I ſee no reaſon why the emulgent arteries ſhould haue beene made ſo large, vnleſſe it were for the expulſion of this excrement. *Ariſtotle* amongſt al the Philoſophers is againſt this, *Hippocrates* in his fourth Booke *de morbis* laboureth might and maine againſt it, yeelding diuers reaſons why it cannot bee: but wee muſt vnderſtand that *Hippocrates* laboureth to proue that all the drinke goeth not into the Lungs, hee confeſſeth that ſome ſlippeth by. And thus *Galen* in his eight Booke *de placitis Hippoc. & Platonis* reconcileth *Hippocrates* to himſelfe; namely, that ſome of the drinke falleth inſenſibly downe along the weazon, the reſt

Why the emulgent arteries are ſo large.

reſt paſſeth ouer the *Epiglottis* into the ſtomack: but if neuer ſo little a crum of ſolid meate get into the weazon, it bringeth danger of ſuffocation. So *Anacreon* the Poet was ſuffocated with a Grape-ſtone. And *Fabius* the Senator is ſaid to haue beene ſtrangled with a haire which got into his weazon in ſupping of a draught of Milke. *Alexander Benidictus* writeth that a mother at *Bruſſels* thruſt a pill downe her childes throate with her finger, vpon which it preſently dyed.

Examples of ſuch as haue beene choked with crums or ſuch like.

And thus much ſhall be ſufficient to haue beene ſaide concerning the vitall parts belonging to the middle Region called the Cheſt, with all the Controuerſies and ſubtleties of Nature therto appertaining. It followeth now that we ſhould aſcend vnto the Throne of the ſoule, the Tower of the body, which is the Head.

Concluſion of the diſcourſe of the vitall parts.

The End of the Sixt Booke and the Controuerſies thereunto belonging.

THE SEVENTH BOOKE,

Of the Third and vpper-most Venter called the HEAD, wherein are described the *Animall Organes.*

The Præface,

Wherein is conteyned the Summe of the first Eight Bookes.

AS a Traueller that desireth to make profit of his paine, when he hath passed one Citie before hee enter into another will recount with himselfe his principall obseruations, especially when the recognition of the former may stand him in steade for his better vnderstanding in that to which hee bendeth his course: so I thinke it not amisse hauing passed through so great variety of partes in the two former Regions of the body of Man, before I enter into the Third, to cal vnto your remembrance (not al the particulars before rehearsed, for that would be irkesome to vs both Gentle Reader) but the Principall, as wel to refresh thy memory, as also to make a more easie passage vnto that which followeth.

MAN who is the subiect of our whole Discourse, consisteth of a Soule and a Body. The Soule is the Lady and Mistris, the Soueraigne and Commander. The Body is a most perfect Organ or Instrument of the reasonable Soule, consisting as *Hippocrates* well saith (though obscurely) *of Fire and Water.*

Why the body is made of many organs.

For the Soule, albeit when shee is free from the prison of the Bodye can see without an Eye, heare without an Eare and by her owne simple act discourse without the help of spirits; yet so long as she is immured within these wals of clay shee cannot contemplate the speculations of Externall things without an Externall *medium*; and therefore Nature (by which I vnderstand the wisedome of the eternall Creator) framed the body of many Organicall parts whereby and wherein the Soule might exercise her Diuine administrations, produce and exhibit the powers and efficacies of her manifold Faculties. For the Body in deede is but a dead trunke till the Soule arriue into it, and quickneth it vnto the performance of perfect actions of life.

But because the Soule is of all Formes the most excellent as being created immediately partaker of immortality, Nature in emulation of the diuine *Numen* hath striuen to make her habitation also immortall, which although the destiny of the matter did gainesay, yet she hath brought to so admirable a perfection that it is worthily called Θαῦμα θαυμάτων, *the wonder of Wonders, the Myracle of Nature, and a Little world.*

why the spirit was created.

WHereas therefore there was no proportion or correspondencie betweene mortality and immortality, betweene the Soule and the Body; Nature with wonderfull skil, out of the principall part of the seede did extract and separate a spirit which lay lurking in the *power* of the Matter, a spirit I say of a Middle nature betweene Heauen and Earth, by whose mediation as by a strong band the diuinity of the soule might be married to the humanitie of

of the body. This instrument of Nature we call Fire, which moueth and illustrateth the whole packe of the members, and moderateth all and singular actions of life, of which also it is the next and most immediate cause.

But because the nature of Fire is such that it hath in it much forme and but a little matter, neither can diffuse the beames of his light vnlesse it be receiued into some substance wherein his power may be vnited; therfore it was necessary there should be another Principle not so subtle, wherein this ætheriall body might expatiate and disport it selfe according to the diuersity of his functions and that without danger of expence. Such a Principle is the mutuall confluence of the seeds of both parents, out of whose slimy matter the *Plasticall* or formatiue faculty of the wombe stirred vp by the vigor of heate diduceth and distinguisheth the confounded *power* of the parts into their proper actions, not without a discerning Iudgement and naturall kinde of discourse. This masse of seed irrigated with the *power* of the whole body according to *Hippocrates* I call *Water*; not onely because this Element doth delineate nourish and make fruitefull, but also because the future siccitie and hardnesse of the spermaticall parts stood in neede of a moist and viscid matter whereby those things which otherwise could hardly be sammed together might receiue their conglutination, that so of many dissimilar particles, one continued frame might arise. The second principle.

This farme thus coagmentated and distinguished for the seruice of the soule, we haue in the beginning of this work compared to the whole world or vniuerse, and that not without good ground. For as of the world there are three parts, the Sublunary which is the baselt, the Cœlestiall wherin there are many glorious bodies, & the highest Heauen which is the proper seate of the Diety. So in the body of man there are three Regions. The lower Belly which was framed for the nourishment of the *Individuum* & propagation of mankinde. The middle Region of the Chest, wherein the Heart of man the sunne of this *Microcosme* perpetually moueth and poureth out of his bosome as out of a springing fountain the diuine Nectar of life into the whole body, and the vpper Region or the Head wherein the soule hath her Residence of estate, guarded by the Sences and assisted by the Intellectuall faculties at whose disposition all the inferior parts are imployed. How the body is like the world.

In the lower Region Nature hath placed two parts more excellent then the rest, wherof one endeuoureth & attendeth the conseruation of the *Individuum*, the other of the Species or kinde. The first is the Liuer which some haue said is the first of all the bowels, both in respect of his originall & of his nature. It is seated in the right *Hypocondrium* vnder the midriffe. The figure of it (if you except his fissure) is conuexall, but vnderneath vnequall and hollow, aboue smooth and gibbous. In a man this bowell is proportionably greater then in any other creature, and greatest of all in such as are giuen to their bellies. The proper *parenchyma* or flesh of this Liuer, which is most like to congealed and adust bloud, by a proper & inbred power giueth the forme, temper and colour of bloud to the Chylus confected in the stomacke, deriued into the guts, prepared in the meseraick veines and branches of the gate-veine by which also it is transported to the hollow part of the Liuer, there as we saide wrought and perfected, and so conueyed by the same rootes of the gate-veine, and thence exonerated into that which is called the *Caua* or hollow veine; by whose trunks and boughes it floweth into the whole body. The temperament of this Liuer is hot and moist; for the moderation of which heate and conseruation of the spirits therein contained it receiueth certaine small Arteries which attaine but onely vnto the cauity thereof. It is inuested round with a thinne coate wherein two small Nerues belonging to the sixt coniugation of the braine are diuersly dispersed. The lower Region. The Liuer.

We say moreouer; that this same Liuer is the shop or work-house of the venall bloud and the originall of the veines; in whose thrummed rootes the more aery portion of the Aliment is conuerted by the in-bred and naturall faculty of the Liuer into a vaporous bloud, which becommeth a naturall, thicke and cloudy spirit, the first of all the rest and their proper nourishment: which spirit is the vehicle of the naturall faculty, and serueth beside to helpe to transport the thicker part of the bloud through the veines into the whole bodye; where it needeth but a little ayer and therefore is refreshed and preserued only by Transpiration made by the Anastomoses or inoculations of the Arteries with the veines in their extremities or determinations. This Naturall faculty (we before mentioned) is diuided into three faculties, the Generatiue, the Alteratiue and the Increasing faculty. Of the Generatiue we shall speake by and by. The action of the Alteratiue faculty is Nutrition which hath many handmaides attending her, Attraction, Expulsion, Retention, and Concoction. The Naturall faculty.

on. The action of the Increasing Faculty we call Accretion, that is, when the whole body encreaseth in all his dimensions. Finally, wee say that Concupiscence as it is a distinct Faculty from Reason and Rage, ruleth and beareth sway in the Liuer as in her proper Tribunall, and is distinguished into *Libidinem & Cupediam*, *Lust* and *Longing*.

The partes of Generation.

But because in all her workes Nature euer intendeth immortality, which by reason of the importunate quarrell and contention of contraries she could not attaine in the *individuum* or particular, she deuised a cunning stratagem to delude the necessity of Destiny, & by an appetite vnto the propagation of the kinde, hath sowed the seedes of eternity in the nature of Man. For the accomplishing of which propagation shee hath ordained conuenient instruments in both sexes, which are for the most part alike, but that the instruments of the Male are outward, those of the Fœmale for want of Naturall heate to driue them foorth are deteyned within. The Chiefe of these are the Testicles, two Glandulous bodies of an ouall Figure which in men hang out of the *Abdomen* and are inuested with four Coats, whereof two are common, the *Scrotum* or Cod a thin and rugous skinne, and the *Darton* which hath his originall from the fleshy Panicle. The other two are Proper, the former is called *Erytroides*, and the latter *Epididymis*. The temperament of these Testicles is hot and moyst, and they haue a very great consent with the vpper parts especially with the Middle Region, as also hath the wombe. The manner of the Operation of the Testicles is thus.

The Testicles

The matter of the seede, together with the spirites carrying in them the forme and impression of all the particular parts and their formatiue Faculty, falleth from the whole body and is receiued by the Spermaticall Vesselles, in whose Labyrinths by an irradiation from the Testicles it is whitened. After it is so præpared it is conueighed to the *Epididymis* thorough whose insensible passages it sweateth into the spongie and friable substance of the Testicles themselues; where hauing atteined the forme and perfection of seede it is deliuered ouer by the eiaculatory or rather the Leading-vessels to the *Parastatæ*, and from them transcolated to the *Prostatæ*, which reserue the seed being now turgid and full of spirits for the necessary vses of Nature. Hence it followeth that that power which is called σπερματοποιικὴ, that is, the *seede-making* Faculty, or the Faculty of generation, is from the Testicles immediately, by which Faculty the parts being stirred vp do poure out of themselues the matter of the seede when *Venus* dooth so require. This Faculty is the author in men of Virility and in women of Muliebrity and breedeth in all creatures that ἐμψὺ by which the heate being blowne vp is the cause τῆς ὀργῆς, so that the bloode being heated and attenuated distendeth the Veines, and the bodie or bulke of that part groweth turgid and impatient of his place, which the Grecians call ὀργᾶν. And thus much of the Lower Region.

The Middle Region.

In the Middle Region there are many parts of great woorth, but the excellencie of the Heart dimmeth the light of the rest, which all are to it but seruants and attendants.

The Heart.

The Heart therefore is called καρδία ἀπὸ τῆ καδαίνεσθαι, which signifieth *to beate* because it is perpetually mooued from the ingate to the outgate of life.

This is a Pyramidal Bowell whose *Basis* is in the middle of the Chest, the *mucro* or point reacheth toward the left side. The magnitude but small that the motion might be more free and nimble, the flesh very fast and exceeding hot intertexed or wouen with all three kinds of Fibres, and nourished with bloode which it receiueth from two branches of the Coronary Veine.

On the out-side it hath a great quantity of fat and swimmeth in a watерish Lye which is conteyned in the *Pericardium* wherewith as with a purse the Heart is encompassed.

On the inside it is distinguished by an intermediate *partition* into two Ventricles. The right is lesse noble then the left and framed mostwhat for the vse of the Lungs. It receiueth a great quantity of blood from the yawning mouth of the Hollow-vein, and after it is prepared, returneth the same blood againe through the Arteriall veine into all the corners of the Lunges. This right ventricle hath annexed to it the greater eare and sixe Values are inserted into the Orifices of his vessels. The left Ventricle which is also the most noble hath a thicker wall then the right, because it is the shop of thin blood and vitall spirites. Out of this Ventricle do two vessels issue, the first called the Venall artery which receyueth the ayer prepared by the Lungs and for retribution returneth vnto them vitall blood and spirits; at which artery the left deafe eare is scituated, and in whose orifice there stande two Values bending from without inward. The other vessell of the left Ventricle is the *Aorta*

or

or great Artery which distributeth vnto the whole body vitall blood and spirits. For according as the opinion of some is, it draweth the better part of the Chylus by the Meseraicke Arteries into the bosome of the left ventricle for the generation of arteriall blood, and at his mouth do grow three Values opening inward. We say further that the Heart is the habitation of the vitall Faculty, which by the helpe of Pulsation and Respiration begetteth Vital spirits of Ayer and Blood mixed in the left ventricle. And this Faculty although it be vitall yet is it not the *life* it selfe, and differeth from the Faculty of Pulsation both in the functions and in the extent and latitude of the subiect. The Faculty of Pulsation is Naturall to the heart, as proceeding and depending vpon the Vitall Faculty. For it is not mooued προαιρετικῶς or voluntarily as is the Animall Faculty, but onely obeyeth the command of the necessity of Nature. The Vitall faculty.

From the foresaide Faculty of Pulsation do proceede two motions, the *Diastole* & the *Systole*, betweene which there is a double Rest. These motions in the Heart and Arteries are the same and at the same time, but so, that the cause of the motion is supplied from the Heart vnto the Arteries as from a principle both mooued and mooving.

Finally, to come vnto that which we are now in hand withall. In the vpper Region wee meete with the Braine compassed with the strong battlements of the scull, adorned with the Face as with a beautifull Frontispice wherein the Soule inhabiteth, not onely in essence and power as it is in the rest of the body; but in her magnificense and throne of state. This Braine is the most noble part of the whole body and framed with such curiositie, so many Labyrinthes and Meanders are therein, that euen a good wit may easily bee at losse when it is trained away with so diuers sents in an argument so boundlesse and vaste. Notwithstanding we will as briefely and succinctly as we can giue you a viewe of the Fabricke and Nature thereof, referring the Reader for better satisfaction to the ensuing discourse, wherein we hope to giue euen him that is curious some contentment. The vpper Region.

The substance therefore of the Braine is medullous or marrowy, but a proper marrow not like that of other parts; framed out of the purest part of the seed and the spirites. It is moouable and that with a naturall motion which is double, one proper to it self, another comming from without. It is full of sence, but that sence is operatiue or actiue not passiue. For the behoofe of this braine was the head framed, nor the head alone but also the whole body, it selfe being ordained for the generation of animall spirits and for the exhibiting of the functions of the inward senses and the principall faculties: in this brain we are to consider first his parts then his faculties. The Braine.

The Braine therefore occupieth the whole cauity of the skull, and by the *dura mater* or hard membrane is diuided into a forepart and a backpart. The forepart which by reason of the magnitude retaineth the name of the whole and is properly called the Braine, is againe deuided by a body or duplicated membrane resembling a mowers sythe, into a right side & a left, both which sides are againe continued by the interposition or mediation of a callous body. This callous body descending a litle downward apeareth to be excauated or hollowd into two large ventricles much resembling the forme of a mans eare, through which cauities a thrumbe of crisped vessels called *Plexus Choroides* doth run, wherein the Animal spirits receiue their preparation; and out of these Ventricles doe yssue two swelling Pappes which are commonly called the Organes of smelling and do determine at the spongy bone aboue the top of the nose.

These two venticles are disseuered by a fine and thin body called *speculum lucidum*, or the *bright Glasse*, vnto which adioyneth the Arch of the braine called *Corpus cameratum* which is supported by three finials or Columnes which like *Atlas* do sustaine the weight of the braine, so that the thirde ventricle which lieth vnder them is not obliterated. This middle ventricle which is a common cauity of the two vpper, occupieth the very center of the braine and runneth out with a double passage. The first descendeth to the Basis of the braine where the originall of the Nerues is most manifest, and the extremity thereof endeth in a portion of the *Pia mater* or thinne membrane very like vnto a Tunnel, through which Tunnell the flegmaticke excrement of the braine is transcolated into the pituitary glandule thereunder disposed, and so thorough the holes of the wedge-bone distilleth into the Pallate of the mouth.

The other passage of the thirde Ventricle which is larger then the former is directed vnto the fourth Ventricle where the Glandule or Kernell called κονάριον is seated, at each side of which do adioyne the *Buttockes* of the Braine, and vnder them the *Testicles* appeare, which

which ſeuer the paſſage of the Animall ſpirit out of this into the fourth ventricle. Finally, the fourth ventricle ſucceedeth, which is the leaſt and moſt ſolid of all the reſt, and wherein ſay ſome, the Animall ſpirit receiueth his vtmoſt perfection, and therefore it is made in the Cerebellum that is, the backe-ward or after-braine, which for this very reaſon was framed of a harder conſiſtence then the former. And ſo much of the parts of the braine.

The Animall Faculty.

Now for the faculties; we determine that the Braine is the Pallace of the Rationall Soule, which ſoule vſing for her inſtrument the temper & confirmation of the braine, according to the diuerſity of her functions bringeth forth mixt actions by the mediation of the animall ſpirit. Theſe very actions, produced according to the variety of the temperament and *medium*, into diuers acts of Ratiocination Imagination and Memory as the ſoule is beſt pleaſed to worke, we call Faculties; which are ſeated and eſtabliſhed together & promiſcuouſly in one and the ſame place.

Againe, we ſay that this braine as it is the beginning of the inward, ſo is it alſo of the outward ſenſes, from which each of them receiuing their proper veſſels or paſſages together with their Faculty do ſuffer the incurſions of Species or Images reſorting vnto them according to the diuerſity of the Organe. The eye receiueth the viſible formes, the eare the audible, the noſe ſuch as caſt an odour from them; and ſo of the reſt. All theſe indiuiduall formes receiued by the ſences, are by them reſigned vp in token of fœalty to the Common ſenſe or priuy-chamber of the ſoule from whence they receiued their faculties: and then out of thoſe formes the ſoule gathering phantaſmes or notions doth eyther lay them vp in the Memory, or worke vpon them by diſcourſe of Reaſon. Finally, we attribute to the braine the faculties of ſenſe or motion, which faculties together with the animall ſpirit differing in forme and kinde from the vitall, and prepared concocted and perfected in his ventricles and ſubſtance, he doth continually and without intermiſsion tranſmit through the ſame Nerues into the whole body to ſupply the expence of the foreſaide ſpirits, which is made either by action or by paſsion.

And thus haue wee runne through not onely the two lower Regions to refreſh our memories, but alſo the vpper, wherein the Reader may haue ſuch a taſte of that which followeth, as may haply make him fauour it the better when he commeth thereto. And ſo wee proceede to our buſineſſe.

CHAP. I.

Of the Names, ſcituation, forme and parts of the head.

HAuing hitherto as exactly as we could and with great leaſure made our progreſſe through the two lower Regions Naturall and Vitall, it is now time we ſhould aſcend into the third venter, the ſeate & very reſidence of the ſoule, the ſacred Pallace or Tower of Pallas, & there ſuruay her royall Court, her guard of outward Sences, her Councellors of ſtate and all their æquipage.

This Region therefore is by the *Græcians* called κεφαλὴ κάρτον & κεφάλη, *Appians* Interpreter holds it was called κεφαλή, of a word which ſignifieth to grow dry, becauſe being of a bony ſubſtance it muſt needs be dry. *Apollidorus* deriues it from the word καλύπτω to hide or couer, becauſe it is the couering of the braine. Others becauſe there κεῖται τὰ φάη the lights are placed. Others ἀπὸ τῦ κεκυφῶσθαι, from the Cauity or hollownes of it. The *Latines* call it *Caput*, becauſe from hence the ſences do *Capere initium* take their beginning.

The names of the head.

There is a double acception of the word *Caput* among Phyſitions, one ſtrickt & preſſe, another large and ample. In the ſtrict ſignification it is vſed by *Celſus* out of *Hippocrates* booke of the wounds of the head and thus diſcribed. The Head is the Manſion and skonce of the braine, whoſe skull is made of two Tables, between which is a marroweye ſubſtance called *Diploïs*, inuironed with Caruncles and ſmall veines, ouer which is ſpread the membrane called *Pericranion*; which Membrane is couered againe with the hairy ſcalpe; but vnder the skull lyeth the Membrane called *Dura mater*. And in this ſignification the antients called it ἄγγειον τῦ ἐγκεφάλυ, the Veſſel of the braine; we alſo in our common ſpeech call it the *Skonce*.

A ſtrict ſignification. *Celſus* deſcription of the Head.

Skonce.

The large ſignification.

But in the large and ample ſignification, vnder the name of the head we vnderſtand all that is circumſcribed within the firſt racke-bone of the Necke and the top of the Crowne. We will intreate of it in this large ſignification: wherein therefore we are to conſider of the

the forme, the ſcituation, the magnitude, the frame and ſtructure, the motion & the particular parts thereof.

First therefore the head was made round and that for diuers reaſons. Inprimis. That it might be of greater receipt and capacity, becauſe it was to receiue the vaſt and huge bulke of the Braynes. For the braines of a man are foure times as big as of an Oxe: now of all figures the round figure is of moſt capacity, witneſſe the world it ſelfe. The forme.

Secondly, the head was made round *ad ſυσπάθειαν*, that it might bee leſſe ſubiect to outward iniuries nor ſo eaſily wounded. For this figure as it is moſt capacious, ſo is it the ſtrongeſt, becauſe it hath no aſperity whereupon a blow might faſten, but is euery where alike ſmooth, hauing no point whence the diſſolution of it ſhould commence. Why round.

Thirdly, the head is round for his better motion, that it might be ſpeedily aud eaſily turned to euery ſide. The *Platomiſts* thinke that the head was therefore made round, becauſe it is the ſeate and habitation of the ſoule. For the ſoule is infuſed into vs out of heauen which is round. Adde heereto that the moſt Noble member deſerued the moſt noble figure.

Notwithſtanding though the figure of the head be round, yet is it not exquiſitely and to a haire globous, but ſome what long, ſwelling out with two tops like promontories, which therefore they call heads of land; it is alſo preſſed on the ſides. Long it was to containe the braine and the Cerebellum; ſwelling out before becauſe of the mamillary proceſſes which are the Organes of ſmelling, and behind to admit the originall of the marrow of the backe. Why compreſſed.

It is preſſed on the ſides, but more forward: firſt becauſe the proceſſe of the backe called *Dorſalis* is much thicker then that ordained for the outlet of the Nerues of the face. Secondly, becauſe in the forepart there was to be a boſome or hollowneſſe, into which the aer was plentifully to paſſe, that is, the mouth. Thirdly, that the eyes rowling on eyther ſide, might not haue their proſpect hindred by the bones of the temples, which would haue beene if the skull in that place had beene more embowed. Laſtly, that the head might ſtand equally ballanced; for ſeeing the forepart hath his waight increaſed by the Iawes, the head would haue waighed too much forward if the back-part had not beene more embowed and runne out as it were into a knowle, which therefore with little alteration in the word and leſſe in the ſence we call the *nowle* of the head. More on the fore-part.

But deſcanting thus about the figure of the head, it muſt be vnderſtood that we meane a head Naturally diſpoſed; for otherwiſe of vnnaturall formes ſome are perfectly round, others do riſe vp in the toppe likk a ridge almoſt of a houſe, bearing bredth little in the Crowne. The round head they call in Greeke *τραλυλον* becauſe it hath no *προβολὴ* or ietty eyther in the forehead or in the nowle. The ſharpe or turbinated head is called *φοξὸς* or as *Athenæus* hath it *φαοξός* becauſe to them that behold it, it ſeemeth ſomewhat ſharpe like a ſuger-loafe. Such a head had *Therſites* in *Homer* much like thoſe moulded Cups among the *Gracians* which were called *φοξοὶ χυλα*. *Euſtathius* rather thinketh it is called *φοξὸς* quaſi *φλοξὸς* of *φλὸξ* which ſignifieth flame, becauſe flame endeth in a ſharpe Cone or ſpire. But of the formes a little more heereafter when we will alſo exhibite the pictures both of the Naturall and of the vnnaturall formes. Naturall heads. Vnnaturall. *Therſites* in *Homer*.

The magnitude of the head is diuers in diuers creatures, yet greater in man then in any other, becauſe his braines are of a bigger bulke. A little head is alwayes faulty, becauſe it argueth both the impotency and weakneſſe of the forming faculty and alſo the want of ſpermaticall matter. Whence it is that Phyſiognomers ſay, that a little head betokeneth a ſudden and raſh wit, becauſe in ſuch there is want of ſpirits, which being pent vp in a narrow roome, are heated aboue meaſure, and beſide haue no ſpace to mooue themſelues in. The magnitude. A little head.

A great head, if other things be æquall, that is, if there be an equal proportion of all the bones is alwayes laudable. Whence *Hippocrates* in the ſixt Book of his *Epidemion*, ſayeth that we muſt eſteeme and meaſure the nature of the bones according to the magnitude of the head: not that the bones doe ariſe from the head, but becauſe all the bones ſhould proportionably anſwere to thoſe to which they are articulated or ioyned. For example, The bones of the arme to the ſhoulder bones, the hippes to the holy-bone, the holy-bone to the racke-bones, the racks to the marrow of the back, the marrow to the brain, the brayn to the skull. A great head. *Hippocrates* expounded.

But *Ariſtotle* in his Problemes ſayth that a man is the wiſeſt creature, becauſe he hath *Ariſtotle* expounded.

a little and a ſhort head. We muſt vnderſtand that by *paruitie* he meaneth the thinneſſe of the bones and the fleſh, not that the inward cauity of the skull is little in reſpect of other creatures.

The ſcituation. The head is ſituated in the higheſt place, becauſe ſay the *Platoniſts* it behoued that the intelligible faculty of the Soule, as the Queene and Princeſſe of the reſt ſhould ſit in an eleuated Tribunall, that the *Iraſcible* and *Concupiſcible* faculties as handmaydes ſhould reſt at her feete, be ſeruiceable vnto her and obey her commands. *Galen* doeth not ſay in his 8. Booke of the *Vſe of parts* (though *Auerrhoes* would father it and faſten it vpon him) that the head was made for the eies; (for it was made onely for the braine) but he ſaith indeede that it was lifted vp into the higheſt place becauſe of the eyes. For the eies being ordained as ſcout-watches, to looke out for vs night and day; it was requiſite that their ſtation ſhould bee in the higheſt place; but becauſe the ſight ſtoode in neede of the ſofteſt ſinew and the ſhorteſt, leaſt his ſoft body if it had beene any thing lengthned might haue beene in danger of breaking: therefore it was neceſſary that the braine which is the originall of ſinewes ſhould be placed neare the eies: neither doth this ſcite of the braine auaile the eies onely, but alſo all the ſences, for the ſmel better apprehendeth an aſcending vapour, and the voice is better heard from aboue.

Galen. *Auerrhoes.*

Why the brain is ſet higheſt.

The parts of the head and their names. The Head is diuided into two parts, the one is haytie the other without haire: the hairy part is called τριχωδὲς, *Calua* the ſcalp; that which is without haire is called πρόσωπον, *Facies* the face. The ſcalpe from the cauity and roundnes of it is called by *Ariſtotle* in the firſt Booke of his Hiſtorie of creatures and the 7. Section, and by *Pollux* σκαφίον. This comprehendeth all the vpper part, backward as farre as the haire groweth, forward to the foreheade: it hath three partes. The forepart reacheth from the foreheade to the Coronall ſuture or crowny ſeame & taketh vp almoſt halfe of the head; it is called βρέγμα ἀπὸ τὸ βρέχειν which ſignifieth to water, becauſe it is the ſofteſt and the moyſteſt; *Sinciput* alſo of the Latines, as if it were *ſummum caput* the top of the head, although there be a higher place.

The parts of the ſcalp.

Hippocrates. *Ariſtotle.* The backpart of the ſcalp reacheth from the Lambdall ſuture to the firſt rack-bone of the necke. *Hippocrates* in his Booke *de vulneribus capitis*, calleth it κόλις. *Ariſtotle* ἰνῶδες καὶ νευρῶδες εἶναι, becauſe it is fibrous and neruous, for many tendons reach vnto it; beſide almoſt all the nerues ariſe from about that part, in Latine *occiput* or *occipitium* as *Plautus* hath it; we call it the nowle. The middle part of the ſcalpe betweene theſe is gibbous or round called in Greeke κορυφὴ of κρύπτω to hide as it were κρυφὴ, becauſe that part of the head is eſpecially couered with haires.

Galen. *Galen* in the 11. Booke of the *Vſe of parts* and the 14. Chapter, calleth it *aruum pilorũ* the Field of haires: the Latines call it *vertex*, becauſe in that place the haires runne round in a ring as waters doe in a whirle-poole. Finally, the ſides of the ſcalp betwixt the eyes, the eares and the necke are called κρόταφοι, παρὰ τὸ κροτεῖν πεϱὶ τὴν ἀφὴν, ſayeth *Ariſtotle* in his firſt Booke of his Hiſtory and the eleauenth Chapter, becauſe the pulſe is there very manifeſt, the Latines cal them *Tempora*, becauſe their gray haires and ſunken fleſh bewray the age of a man.

Another diuiſion of the parts. Containing. Againe, the parts of the ſcalp are contayning and contayned. The contayning parts are ſome of them Common ſome proper. The Common, are the *Cuticle* or ſcarfe-skinne, the true skinne bearing a wood or buſh of haire, the fat and the fleſhy pannicle. The proper contayning parts are either externall or internall. The externall are two membranes, *pericranium* and *perioſtium*, certain muſcles and the bones of the head. The proper inward conteyning partes are the two mothers called *Meninges*, *dura* and *pia*, which encompaſſe both the skull and the braine.

Contained. The parts contayned are the braine and the *Cerebellum* or after-braine, from which ariſeth the marrow, which when it is gotten out of the skull is properly called the marrow of the backe, or pith of the ſpine, from which doe ariſe many nerues as well before it iſſue out of the skull as after. Of theſe we will firſt entreat, and then after of the part without hayre or the face in the booke following.

CHAP. II. *Of the common containing parts of the head.*

5. common parts. THE common contayning parts of the head are fiue; the Haires, the Cuticle, the Skinne, the Fat and the fleſhy pannicle; of all which wee haue ſpoken heretofore at large; yet becauſe in euery one of theſe there is ſome difference from the ſame parts in other places of the body wee muſt a little here inſiſt vpon them: and firſt of the haires.

Albeit

Albeit therefore the haire is generally more or leſſe all ouer the body as before is ſayd, yet aboue all places the head is adorned with the greateſt aboundance of them. The haires of the head are the longeſt of the whole body, becauſe ſayeth *Ariſtotle* in his firſt Booke *de Generatione Animalium* and the third Section the braine affoordeth toward their nouriſhment a large ſupply of humour or vaporous moyſture whether you will, which alſo is moſt clammy and glutinous. *Ariſtotle.* For the braine is the greateſt of all the glandulous bodies. They are alſo in the head ſtiffeſt, becauſe the skinne of the head is the thickeſt, yet is it rare and full of open pores, ſo ſayeth *Galen* in his ninth Booke *de vſu partium* and the firſt Chapter. *Galen* In the head Nature hath opened conſpicuous and viſible waies for the vaporous and ſmoky or ſooty excrements, for the head is ſet vpon the body as a roofe vppon a warme houſe, ſo that vnto it doe ariſe al the fuliginous & vaporous excrements from the ſubiected parts. *Pol'ux. Eſchylus.* The haires of the head are called in Latine *Capilli*, as it were *Capitis pili*, by *Pollux* and *Eſchylus* κάρη of κείρω to cutte. In men they are called ἰθείραι *Caſaries*, becauſe they are often mowed; in women κόμη of κομέω to dreſſe with diligence, from whence haply wee haue our worde to combe, or rather from the Latin word *Coma*, whoſe ſignification is all one with the former. In woemen they are diuided by a line, which ſeparation the Greeks call λύσωμα the Latins *diſcrimen* and *æquamentum*, in Engliſh we cal it the *ſhed of the haire*.

The skinne of a man although in compariſon of other creatures it is moſt thinne; yet if you compare the skinne of the head with that of the cheſt or the lower belly it is very thick as alſo is the cuticle. *The skin of the head.* And therefore *Columbus* inſulteth ouer *Ariſtotle* for ſaying that the skinne of the head is very thinne.. The place is in the 3. Booke of his hiſtory and the eleauenth Section, where hee doth not ſay that the skinne of the head is very thinne, (for in the fift Booke *de Generatione Animalium* and the third Chapter, hee calleth the skinne of the head παχύταλον, that is, very craſſe and thicke) but he ſaith and that truely that the skinne of a man in reſpect of his magnitude is very thin. *Ariſtotle* redeemed.

Well, the skinne of the head as it is the thickeſt, ſo ſayeth *Galen* in his ſecond Booke *de Temperamentis* and the 5. Chapter, it is ſo much drier then the skinne of the reſt of the body by how much it is harder; yet is it rare ſayeth *Ariſtotle* in the place next aboue named, that the ſooty excrements might be auoided for the generation of haire as before is ſayed. *The veines.* It hath veſſelles running in it, Veines from the outward braunch of the externall iugulars, which creeping on both ſides are vnited in the forehead, and are ſometimes opned in grieuous paines of the head, and theſe veines running vnder the drie and hairie skinne carrie bloud vnto it for nouriſhment. *Arteries.* Arteries it hath alſo from the outward branch of the *Carotides* deriued to the rootes of the eares and to the temples eſpecially, which bring Vitall ſpirits vpward from the Heart.

It receyueth alſo certaine endes of Nerues reflected vpward from the firſt and ſeconde coniugation of the Neck to giue it ſenſe. *Nerues.* I ſaide ends of Nerues, for ſo ſaith *Gal.* in his ſixeteenth booke *de vſu partium* and the 2. Chapter. *An elegant place in Galen* The skinne hath not a proper & definite Nerue belonging vnto it as euery Muſcle hath his Nerue diſſeminated in or about his body but there attaine vnto it certaine Fibres from the ſubiected parts which connect or knit it to thoſe parts, and alſo affoord ſenſe vnto it. The ſenſe of this skinne of the heade is not fine and exquiſite as in the Cheſt or the Lower belly. *Ariſtotle* in the third booke of his Hiſtorie and the eleuenth Chapter ſaith, it hath no ſenſe at al and rendreth a reaſon becauſe it cleaueth to the bone without any interpoſition of Fleſh. But *Galen* diſproueth this opinion in his ſixeteenth Booke of the Vſe of Parts and the ſecond Chapter. It may bee *Ariſtotle* meant the Cuticle and not the true skinne. *Archangelus.* Or excuſe him as *Archangelus* dooth, who ſayth that he meant it of the true skin, but as it is a ſimilar part diſtinct from a Nerue, for indeede onely the Nerues haue ſenſe. *Why the skin of the head hath but a dul ſence.* *Bauhine* and *Laurentius* giue another reaſon why the skinne of the Heade is leſſe ſenſible, becauſe (ſay they) in the Heade the skinne adhereth but to a Muſculous or fleſhie Membrane, whereas in other parts it cleaueth to a Neruous Membrane.

The vſe of the skin of the head is to compaſſe the ſcull and be a couering vnto it. *The vſe.*

There is no fatte at all ſaith *Platerus* vnder the skinne of the Heade, and hee giueth his Reaſons, firſt becauſe there is no vſe of it, for the ſmall veſſelles vnder the hairie Scalpe are placed in ſufficient ſafetie, there needed therefore no Fatte at all to ſecure them. *The fat.* Secondly, becauſe there had beene an abuſe of it. *Platerus.* For in the infant the Head is proportionably to the other partes exceeding great, but if it had any fatte about it, it woulde haue

bene a great *remora* or impediment in the birth. But *Veſalius* in his ſeuenth Booke & the 18. chapter ſaith, that a man may eaſily with his hands diuide the skin with the fat and the fleſhy Membrane from the ſcull. And *Columbus* ſaith that beſide the Yard and the Codde there is no part but a man may finde fat in it. The trueth is, that in the fore-head there is none at all, for becauſe in the fore-head the skin is moued at our diſpoſition it would haue beene a hinderance to his motion; for that in this place the skin is vnited to a Muſculous ſubſtance, but in and about the *Occipitium* or nowle of the heade there is ſome fat to bee found.

Veſalius. Columbus

The Fleſhie Membrane. *Fallopius.*

The fleſhy Membrane ſpred vnder the skin cleaueth cloſe vnto it in the foreheade, becauſe there is no fat to ſepatate them, and there this Membrane is very thick. It alſo ſometimes runneth like a Tendon from the Muſcles of the forhead to the Muſcles of the nowle and the eares, inſomuch that *Fallopius* warneth vs to take heede leaſt we miſtake it for the *Pericranium*, and the *Pericranium* for the *Perioſtium*. And thus much for the common inueſting parts of the Head, how they differ from the ſame parts in other places of the Bodie.

CHAP. III. *Of the Pericranium Perioſtium, and the Muſcles about the Head.*

Pericranium.

THE Membrane which lyeth next vnder the fleſhye Pannicle is called περικράνιος, becauſe it compaſſeth the whole ſcull on the out-ſide. The Arabians call it *Almocat* and *Almocatin*. *Laurentius* woulde haue it called *Perioſtium*. And *Fallopius* in his Inſtitutions and in his Booke *de Oſſibus* and the 19. chapter ſaith, that this Membrane is common to all the Bones about the ſcull & called *Pericranium*, but by his common name *Perioſtion*. It is ſcituated betwixt the fleſhy Panicle and the *Perioſtium*, to both which it is tied by certaine Fibres. Soft it is and thin, but thight and ſolid ſaith *Laurentius* and of exquiſite ſenſe. It ariſeth from certaine proceſſes of the *Dura Meninx* like thin Membranes or rather Ligaments (for they haue the vſe of Ligaments) paſſing through the ſutures or ſeames of the ſcull. For euerie one of theſe Ligaments are extended ouer that part of the ſcull againſt which they yſſued, and going on meete one with another and are exactly vnited ſo that all of them put together make a common membrane. This membrane dooth not onely encompaſſe the ſcull, but alſo the temporall Muſcles although the Anatomiſtes commonly take it in that place for the coate of the temporal Muſcles or for a Tendon of them, making them to haue two Tendons, one outward another inward, whereas indeede ſaith *Fallopius* in his obſeruations it is nothing elſe but a part of the *Pericranium*. Yet doth it not clothe theſe Muſcles ſo farre as to their inſertion, but onely as farre as the Iugall bones and that for their ſafegarde; and the better it may doe them this good turne becauſe in that place it is thicke and harde; it parteth therefore from theſe Muſcles neere vnto the Iugall bone as is ſaid, where between the Membrane and the Muſcles on either ſide there is a little what of fat to be found.

Fallopius.

His originall.

Progreſſe.

His vſe.

The vſe of this *Pericranium* is to binde and rowle the ſcull on the outſide round about as it were with a rowle or ſwathing band whereby his bones are firmed; it knitteth alſo the *Dura Meninx* to the ſcul, and hangeth it ſo that it cannot fall or preſſe vpon the Braine. *Platerus* addeth that it tyeth vnto it ſelfe the skin of the head and that very ſtrongly, becauſe there is no fleſh nor fat betweene them, and that is the reaſon that onely the skinne of the head when it is wounded needeth not to be ſewed together, becauſe the lippes of it doe not nor cannot ſtart farre aſunder being held together by this membrane.

Platerus.

Perioſtium. Falopius. Bauhine.

Next vnder this lyeth the *Perioſtium*, which ſaith *Veſalius* you may feuer from the *Pericranium* with the point of a knife, although *Fallopius* thinke they are both one, and *Laurentius* conceyueth that Anatomiſts are deceiued by the thickneſſe of the *Pericranium*, which heere was neceſſary becauſe it couereth a noble bone. But *Bauhine* whom we wil now follow deſcribeth them ſeuerally. The *Perioſtium* therefore is a Neruous Membrane and therfore very ſtrong and thin. It cleaueth very ſtrongly to the ſcul as alſo it doth to the reſt of the bones; the reaſon is, becauſe the bones being very hard ſubſtances would not bee altred or affected with any obiect, & ſo want the benefit of the Tactile quality, vnleſſe they had beene couered with this Membrane of exquiſite ſenſe, by whoſe aſsiſtance now they are not deſtitute of feeling; whence by the Grecians it is called περίοστεον, that is, *Circum oſſalis* about the bone; for it compaſſeth all the bones excepting the teeth onely ſaith *Varolius*, but we may alſo except the inſide of the ſcull and the articulations or ioyntes of the bones,

How the Bones feele.

bones; for if it had beene extended ouer the ioynts we could not haue mooued them without paine. Some, saith *Columbus*, being ignorant of this Membrane haue maintayned that the bones themselues are not destitute of sense.

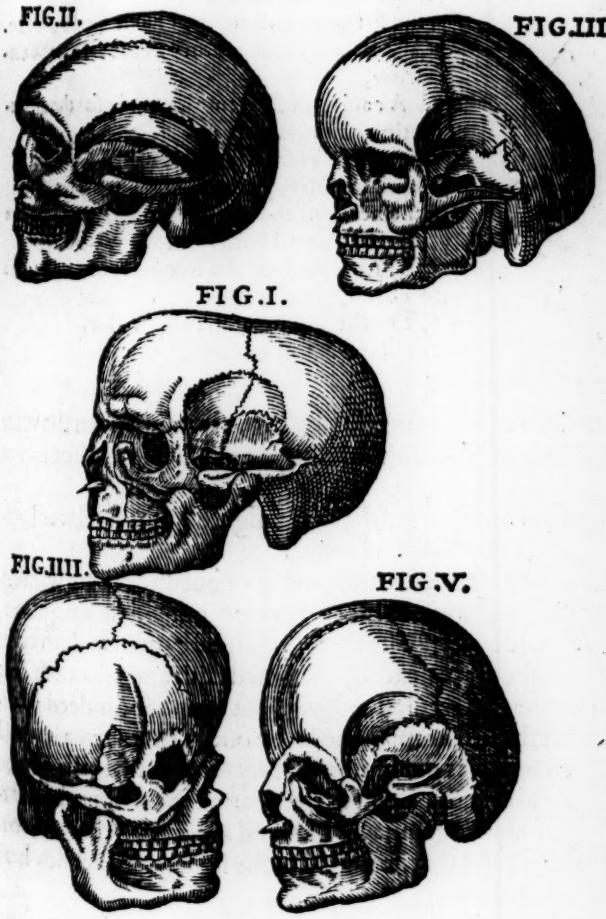
The Muscles about the head are very many, some arise from the lower part of the scull, others are disposed vnder the skinne of the fore-head mouing it for the behoose of the eyes, whereupon the skinne of the fore-head is rugous, full of transuerse and right lines; some also there are couched vnder the hairy scalpe, sometimes (for they are not perpetuall) by which the whole scalpe and the eares in some men are mooued; Finally, others belong to the neather iaw (for the vpper is immooueable) of all which we shall particularlie entreate in our Booke of Muscles. The Muscles about the head.

CHAP. IIII. *Of the diuers Figures of the Head, the Sutures and substance of the Scull.*

BEfore we come to entreate of the Bones and Sutures of the scull, which we purpose in this place but lightly to handle, it shal not be amisse to adde a little to that which hath beene already saide concerning the whole figure and fashion of the head, because if the figure be changed then must the Sutures or seames needs alter both in scituation and in number, as *Hippocrates* saith in his booke *de Ossibus*, and after him *Galen* in diuerse places, although I knowe that there are some great Anatomists who are not of this minde.

Table I. *sheweth the Figures of the Head. Fig.* 1. *exhibiteth the Natural and blameleſſe conformation of the Heade on one side, the other foure Figures are all depraued & faulty.*

TABVLA I.



The Figure therefore of the head is double, Naturall and Good, or else depraued. The Naturall Figure [Ta.1.fig.1] is that which is like a long sphere, on both sides nere the temples by little and little depressed and made narrower, but at each end shooting out; yet so that the backe parte is more capacious, that so it might stand vppon the Necke equally balanced. For because the fore-part though it be not so much compassed nor so much embowed, yet by reason of the bones especiallie of the vpper iawe is some-what heauy, it was needfull that the back-part should be made as heauy by the capacity therof. A double Figure of the head. Natural.

The depraued figure is what soeuer varieth from the former description. I dare not cal it in opposition to the former Vnnatural, because some very good Anatomistes haue interposed their iudgementes & determined that all figures of the head are Natural, albeit they vary somewhat from the exact forme: yet *Archangelus* calleth these depraued figures *Præter Naturam*. Depraued.

This depraued figure *Galen* in his ninth booke *De vsu partium* and the 17. chapter calleth by a Generall name φοξὸν, for in that place he reckoneth the round and globy head as a kinde of that φοξὸν. There be three sortes of them. The first

Table 2. ſheweth ſome bones and ſutures of the head.

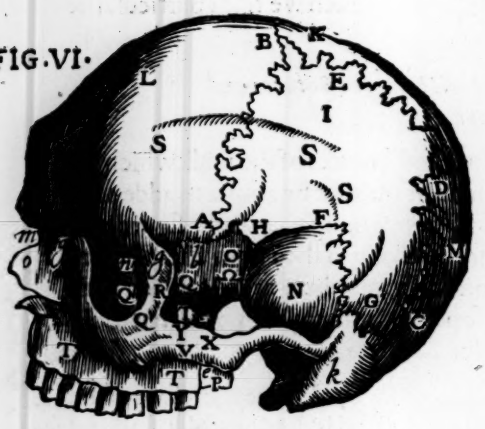
Figure 7. ſheweth the right ſide, the yoke-bone being remoued.

TABVLA. II.

FIG. VI.



VII.

AB, The Coronall ſuture.
CD, The Lambdal ſuture.
E, the Sagittall ſuture.
FGHΩ, the fourth proper circular ſuture.
IK, The bones of the *Sinciput*.
L, the forehead bone.
M, the *occiput* or nowle bone.
N, the bones of the Temples,
O, the wedge bone.
Φ 7, the fourth hole of the wedge bone in the ord of the eie.
P 7, Foure proceſſes of the wedge bone marked with 2,3,4,5.
QQQ the firſt bone of the vpper iaw,
R, the prominence of this bone toward the temples,
SSS, A ſemicircle in the skull, from whence the temporal muſcle doth ariſe.
TT, the fourth bone of the vpper iaw.
VX, the yoke bone.
Y, A ſuture in the yoke bone which ſome haue accounted for the fourth common ſuture.
Ω 6, *aa* 7, the forepart of the fourth proper ſuture.
b, the fift proper ſuture of the skull running obliquely from H to *g*.
c 7, A ſcale growing ſometimes to the wedge-bone
d 7, A line diſtinguiſhing this ſcale from the bone
ee, the lower part of the ſecond common ſuture at the ſides of the pallat,
f 7, the firſt ſuture of the vpper iaw in the cheeke.
ggg, the firſt common ſuture in the ſide of the eie-brow,
h 7, A cauity of the temples made for the articulation of the lawer iaw,
i, the *appendix* of the temples called *Styloides*,
k, the mammillary proceſſe of the temples,
l 7, the heads of the *occiput* or nowle bone where it is articulated with the firſt rack-bone,
m 6, A ſuture betwixt the bone of the iaw and the forehead,
n 6, The third bone of the vpper iaw.

[Table 1. figure 2.] wherein the eminence or out bearing before, ſhooting from the vpper part of the forehead is wanting, although the backward eminence in the nowle bee faire to be ſeene.

The ſecond is quite contrary vnto this, in which [Table 1. figure 3.] the backward out-ſhoote in the nowle is wanting but not that in the forehead.

The third [Table 1. figure 4.] in which both the eminences or out-ſhoots are wanting. There may bee another added to theſe three which many eſteeme but onely imaginarie, and that is when the skull ſwelleth more in compaſſe toward each eare then it doth either forward or backward. But *Galen* in the place next aboue named ſaith and prooueth, or at leaſt ſeemeth ſo to doe, that this is a meere ſpeculatiue thing, but cannot be indeed in Nature, for then ſayth he the fabricke of the braine muſt needes be ouerthrowne, yea it would proue a Monſter and cannot liue. *Veſalius* is of opinion that *Hippocrates* maketh mention of this forme, and beſide telleth a ſtory of an Innocent as wee tearme them or foole in *Venice*, whoſe braine was of that ſhape; *Falopius* gain-ſayes him, and auoucheth that *Hippocrates* made mention onely of three ſortes, and that he miſtooke the figure of the childs head at *Venice* of the ſame minde alſo is *Euſtachius*.

Difference of Anatomiſts.

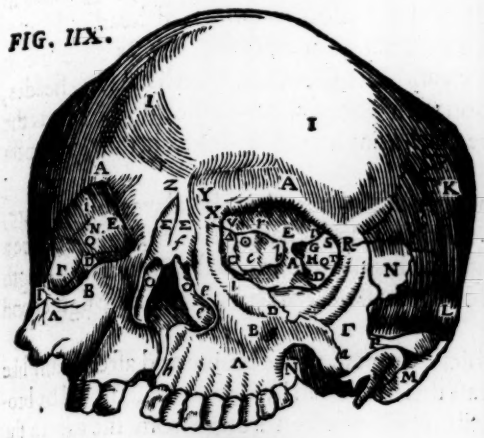
A fift Figure.

There may be a fift figure added out of *Hippocrates*, and that is an acuminated or ſharp figure, wherein the left figure is but a little altered. This figure, ſayeth hee in his booke *de aëre aquis et locis*, and the 35. Text, was firſt made by Art: for the Midwiues vſed to preſſe the

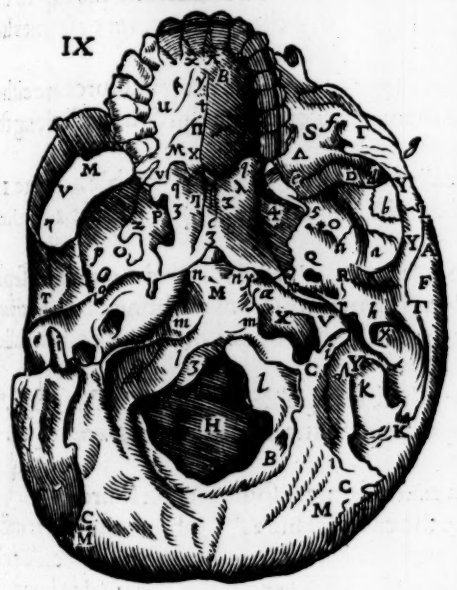
Table 3. Fig. 8. Sheweth the fore-side of the Skull, as also the bones, the holes or perforations and the Sutures both of the Skull and of the vpper Iaw.

TABVLA. III.

FIG. IIX.



IX



A A. A hole in the fore-head bone.
B B. The hole of the fourth bone of the vpper Iaw, which is in the Cheeke.
C. A hole of the second bone of the vpper Iaw in the inward angle of the eye.
D D. The fourth hole of the wedge-bone in the outward side of the eye.
E E. the first hole of the same bone,
G. the second hole.
H, the third hole of the same bone in the seate of the eye.
I I. the forehead bone.
K, the left bone of the *Sinciput*.
L, the left bone of the temples.
M. the mammillary processe of the temples.
N N, the wedge-bone.
Γ Γ Γ, the first bone of the vpper Iaw.
Δ, the second bone of the vpper Iaw,
Θ, the third.
ΛΛ, the fourth in the left eye.
Ξ Ξ, the fift bone of the vpper Iaw in the nose.
O O. the bridge or partition of the Nostrils.
P, the Suture in the yoke-bone.
Q, A part of the second common Suture from the first N, to S.
R S T V Y X Z. the third common Suture drawne obliquely through the Orbe of the eye.
a D, the first externall Suture of the vpper Iaw in the Cheeke, and from thence through the eye to Q.
b the third externall Suture of the vpper Iaw from *b* to *c*.
c, the second externall Suture of the vpper Iaw in the eye.
e, the fourth externall Suture reaching to Ξ.
f, the sixt externall Suture of the vpper Iaw in the middle of the Nose.
g, the second internall Suture in the Nose.
h, the seauenth externall Suture of the vpper Iaw.
i, A bastard Suture of the vpper Iaw at the eye,

Fig. 9, Sheweth the Basis of the Skull, and many holes and Sutures therein.

A, the end of the coronall Suture. C C, the lower additaments of the Lambdall Suture on either side. D, the fourth hole of the wedge-bone in the outside of the Orbe of the eye. F, A part of the fourth proper Suture. H, the great hole of the occipitium made for the Spinall marrow. K, A part of the bone called *Sinciput*. L L, A part of the forehead bone. M M, the lower part of the nowle bone. N, A rift or cleft of the wedge bone which is common to the bones of the temple, drawne on the left side from *n* to *o*. O O, the wedge bone. P, His foure processes marked 2,3,4,5, A R, the sixt hole of the wedge bone at the bottome of the throte, A, the seauenth hole of the same at R. Γ, the first bone of the vpper Iaw. S Λ, the fourth. Π, the sixt, where the cutter betwixt *c* and Π, hath not well expressed the Suture. T T, the bones of the temples on either side. V, the fourth hole of the bones of the temple made for the hearing. Ξ, the bridge or partition of the nose. X, the first hole of the temple bone in his Basis. Y Y, the yoke bone. *a a*, the anterior part of the fourth proper Suture. *b*, the lower part of the fift proper oblique Suture, *c*, the lower part of the bridge of the nose which is like a coulter where 3 is placed, *d* the vpper part of the second common Suture. *f*, the first externall Suture of the vpper Iaw in the Cheeke. *g*, the first common Suture in the side of the brow. *h*, the cauity of the temples whereto the lower Iaw is articulated, *ii*, the appendix of the temple bone called *Styloides*. *k* the mammillary processe of the same temples. *l l*, the knub of the nowle bone, *m m*, the 6 proper oblique Suture of the Skull, *n n*, the 7 trãsuerse Suture, *o p*, A line beginning from the last named Suture which climeth by the temples, & is more like a diuision then a line. *q q*, the lower part of the 2 commõ Suture of the Skull in the hollownes of the nose, *r*, the line of the hole of hearing, *s t*, the stony bones, *t v*, the 5 externall transuerse Suture of the vpper Iaw, *X y*, the 7 externall right Suture, *α β*, A bastard Suture of the vpper Iaw in the Pallate, *γ*, the hole of the eare, *δ*, the 5 hole of the temples neere vnto the processe where Y should be blotted out, B, A hole of the nowle bone which is not alwayes found, E, the 2 hole of the nowle bone made for the 6 coniugation of the sinewes & for the iugular veine & artery, H, the 1 hole of the occipitium or nowle bone for the passage of the marrow, §, the 3 hole for the outgate of the 7 coniugation, *κ λ*, two holes of the nose, *μ ν*, two holes in the Pallate which is accounted the 4 of the wedge-bone, *ξ*, Fiue holes in the basis of the wedge-bone, *π*, the hole of the 4 bone of the vpper Iaw in the Pallate. Note that M, V, at the right side pointeth out the cauity which the yoke bone maketh for the passage of the temporall muscles.

the heads of Infants lightly on euery ſide to make them riſe ſomewhat toward the crowne, and after ſo rowled it with bands till that forme was confirmed; the reaſon was ſaith *Hippo.* becauſe the people had an opinion that it was a ſigne of a generous & noble diſpoſition to be ſo featured; afterward Nature imitated Art and children were ſo borne; *Quintilian* in his ſecond Booke and 17. Chapter, ſaith that *Pericles* had an accuminated head and ſomewhat long, and his words came thronging and thundring out, not peaceably as other mens; ſo we ſee, ſaith *Bauhine*, that moſt of the French and low Countrie men haue long heades, becauſe they vſe to lie with their heades vppon their Temples or on one ſide: whereas the Germanes haue moſt what round heads, becauſe from their very infancie they lye vppon their backes.

A fift.

Finally, *Veſalius* maketh mention of a begger of *Bononia* whoſe head was foure ſquare, ſauing that it was a little broader then long. And my ſelfe haue ſeene in Lincolneſhire a wondrous ſmall head made very like the ridge of a houſe neere vnto ſharpnes al the length through, that boy was a foole and a wondrous great eater; and ſo much of the figures and faſhions of the head.

A ſeauenth ſeene in Lincolnſhire.

The skul.

The skull or *cranium* is all that bone which compaſſeth the braine and after-brain like a helmet, which is not made of one bone, leaſt this brain-pan by one wound ſhould be broken throughout, as we ſee a pot will be, the rift running quite through from the top to the bottome. It is made therefore of many bones ioyned together with ſutures or ſeames like the teeth of two ſawes ſet one againſt the other [tab. 1. and tab. 5. fig. 13.]

Proper ſutures. True.

Theſe ſutures are of two ſortes, proper and common. The proper ſutures are either *true* or *falſe*, the true ſutures are three, two of them tranſuerſe, the third runneth along the head.

The firſt is that which is in the forepart called *Coronalis* [Table 2.^{AB} table 4. figure 11.^{nn}] and diſtinguiſheth the forehead bone from the bone of the *ſinciput* [Table 2.^{L} from^{l} to^{K}.]

The ſecond ſuture is in the nowle [table 2.^{CD} table 4.^{PP}] and is called *Lambdoides* ſeparating the bone of the nowle or *occiput* [table 2.^{M} from^{l} to^{K}] from the bone of the *ſinciput*: this ſuture is ſometimes double, containing in the middle a bone with three corners called *Triangulareos.*

The third ſuture is in the middeſt betwixt theſe two [table 2. figure 1.^{z} table 9. fig. 2.^{oo}] and is called *ſagittalis*, it is a ſtraight ſeame and diuideth the bones of the *ſynciput* [tab. 2. fig. 6.^{IK}] deſcending ſometimes euen to the noſe.

False ſutures.

The falſe ſutures are not ſo conſpicuous as the former; ſome reckon foure.

The firſt are two, on either ſide one aboue the eares [table 2.^{FGH}] aboue the bones called *petroſa* or the rockie bones. They are not properly called ſutures, but are rather ſcalie agglutinations. The ſecond two belong to the bone called *ſphenoides* or the wedge bone, on the forepart and the hindpart.

Common ſutures fiue.

The common ſutures are thoſe that belong as well to the skull as to the vpper iaw, and they are fiue. The firſt is in the outſide of the brow. [table 2. figure 6. and 7.^{ss} table 3. fig 8.^{R} figure 9.^{S}.] The ſecond is double, the vppermoſt is in the outſide of the eye & the hollow part of the Temples [table 3. figure 8. from^{f} to^{e} at figure 9. at^{d} table 2. figure 7. at^{d}] The lowerwoſt is at the ſides of the pallat. [table 3. figure 9. from^{d} to^{c}] The third is in the inner and laterall part of the eye. [table 3. figure 8.^{RSTVXYZ}]

The fourth runneth through the middeſt of the iugall bone [table 2. figure 6.^{Y} table 3. fig. 9.^{Y} fig. 8.^{P}.]

The fift is in the bredth of the noſe and is common [tab. 3. fig. 9. vnder z.] to the *ſphenoides*, or wedgebone and the bridge of the noſe.

The vſes of the ſutures.

The vſe of the ſutures is to giue way to the thicke and ſooty excrements; againe to tye the *dura meninx* to the skull, and to giue way for the filaments of the ſame which make the *Pericranium* and *Perioſtium* as is ſayed; and finally to giue ingate and outgate to the veſſelles.

The ſubſtãce of the skul.

Beſide the ſutures, the skull it ſelfe is craſſe; rare and full of holes.

Craſſe or thicke for the ſecurity of that therein contained.

Rare that it might not be too great a burthen; and full of holes [tab. 4. fig. 11. 12.^{L} tab. 5. fig. 14.^{c}] to giue way to the tranſpiration of ſooty excrements.

His tables.

It is alſo made of a double table as we call it, or of two leaues [table 5. fig. 14.^{aa}] which may beſt be diſtinguiſhed about the place of the browes, the outward of theſe may bee eaten

ten away by the French diſeaſe, the inner remaining ſound.

Betwixt theſe Tables are conueyed Veines and Arteries for the life and nouriſhment of the ſcull, among which veſſels there is a kinde of medullous or marrowy ſubſtance [tab 5. fig. 14. betwixt ª and °ᶜ] which ſome call *Meditullium.* *Meditullium.*

Theſe Tables are oftentimes perforated in many places but without order, thorough which perforations ſmall veſſelles paſſe into the inward Cauity euen to the *dura Meninx.* His perforations.

On the outſide the ſcull is ſmooth, but if you turne the bottome vpwarde it is full of inæqualities and protuberations. Of all which we ſhall entreate more at large in our book of bones.

CHAP. V. *Of the bones proper to the Scull.*

THE bones of the head are of two ſorts, ſome are proper to the ſcul alone, ſome belong to the vpper iaw alſo. The bones proper to the ſcul alone are ſix in number (for wee goe not now preciſely to worke to account the ſmall bones of the eares) thoſe of the Iaw two. The proper bones of the Head.

Tab. 4. Fig. 10. ſheweth the inner and lower part of the ſcul, together with many holes eſpecially thoſe of the Wedge-bone. Figure 11. ſheweth the vpper part of the inſide of the ſcull cut from the Lower.

A, The Wedge-bone. B, his firſt hole.
C, the corner of that hole.
D, the *anterior* tranſuerſe cauities of this bone in which the Optick nerues are hidden.
E, The latter of theſe foureſquare wherein the pituitarie Glandule lyeth.
F, The forward paſſage through which the Flegme gathered together is deriued.
G, The ſecond hole of the Wedge-bone in the vpper part of the orbe of the eye.
H, the third in the bottome of the eye.
I, the ſmall holes of the ſpongy bone.
K, A cleft of this bone through which the *dura meninx* is tied. L 10, 11, the cauity of the for-head bone betwixt the two Tables. (foration.
M, the Wedge-bone in this place hath oftentimes a per-
N, A cleft or ſlit common to the Wedge-bone & bones of the Temples.
O, the laſt of the Wedge-bone. Q, the ſixt hole.
R, the 7 hole in the chops at the bottome of the throate.
SS, 10, 11 and T, Certain inſcriptions or furrowes in the ſcull, impreſſed by the veines of the *Dura Meninx.*
V, the eight hole of the Wedgebone at the noſtrils.
X, The fift hole of the ſame bone. Y, 11, the Fontanell
ZZ A cauity made for the forwarde extuberations of the braine.
a The ſixt hole of the Temple-bones, which is the fourth for the hearing.
b, The ſecond hole of the nowle-bone.
c The third, *d* the firſt, *e* the ſecond,
f, *g*, the two *Poſterior* cauities of the ſcull.
h, 10, 11, the extreamity or ende of the third and middle cauity.
ii, 11, A boſome of this paſſage running thorough the length of the ſcull,
i, 10, A boſome common with the nowle bone.
m, 11, Certaine ſmall holes in the inſide of the bone of the *ſynciput.* *n*, *n*, 11, the Coronal ſuture.
oo, 11, The ſagittall ſuture. *pp*, 11. the Lambdal ſuture.
qq, 10, 11. The 4 ſuture called *Squami-formis.*
rr, The forepart of this ſuture compaſsing ſome part of the wedge-bone.
ſ, A part of the Lambdall ſuture, which ſome call the *6.* proper ſuture.
t, A line that ioyneth the ends of the Lambdal ſuture, called by others the 7 proper tranſuerſe oblique ſuture.
u, *u*. The eight proper tranſuerſe ſuture.
x, The bridge or partition of the ſpongie bone.
aa. The proceſſes of the Wedge-bone called *Clinoides.*

The

The forhead bone.

The first bone of the scull is called *Os Frontis* the fore-head bone: [Tab.2,fig.6,7.[i] Tab. 3,fig.8.[i i]] it is circumscribed with the Coronall suture, [Tab.2,fig.6,[c] fig.7,[A B]] and that which is common to the head and the vpper iaw. [Tab.3,fig.8,[x]. Table 2. fig. 6, and 7,[s]] In this bone on either side the browes [Tab.4.fig.10 & 11 at [L]] there is a notable bosome or hollownesse, wherein is conteyned a soft and medullous matter, or haply it was framed to contein aer for the sense of smelling. It hath two processes, the one reaching toward the lesse, the other toward the greater angle of the eie, & make the vpper part of the orb thereof. The second and third are called *Ossa syncipitis*, [Tab.2 fig.6,[i k]] they are full of dens or small holes on the inside with many inscriptions like the path of a snaile or Emmet [Tab.4 fig 10 and 11 SS] where the vessels runne. They are foure square, of substance in respect of the rest very thin and weak. They are limited backward by the Lambdal Suture [Tab.2.fig 6,[D c]] forward by the Coronall [Tab.2,fig.6,[A B]] and belowe by the scalie Sutures of the Temple-bones. [Tab.2.fig.6,[o F H]]

the side bones *Ossa syncipitis.*

The fourth is called *Os Occipitis* the Noddle or Nowle-bone. [Tab.2,fig.6 and 7[M]. Tab.3, fig.9[M M]] It is ioyned aboue to the bones of the *synciput* [Tab.2,fig.6.[i k]] by the Labdall suture; [Tab.2,figure 6,[c D]] at the sides to the Temple-bones, [Tab.3,fig. 9, in [c]] in the middest to the wedge bone. [Tab.3,figure 9,O O] The figure of it is almost rounde, the substance is very thicke and hard, yet but thin and weake at the side of the great hole made in it, [Tab.3,fig.9.[n] Tab.4.fig.10,[d]] through which the marrow entreth into the rack-bones of the neeke. It hath nine bosomes or hollownesses. On the inside seauen, on the outside two. Fiues holes or outlets; and lastly two processes or heads [Tab.3,fig.9,[l l]] broad, couered with a Cartilage or Gristle which are inserted into the cauities of the first rack-bone of the neck vpon which the head is moued. Backward it hath a small processe like a tooth which is receiued by the first racke-bone.

The Noddle bone.

The temple bones.

The fift and the sixt are called *Ossa temporum* the Temple bones, or *Lapidosa* the stonie bones. [Tab.2. fig.6. and 7[N]. Tab.3 fig.9[r r]] They are ioyned aboue by the scaly Suture [Tab.2,fig.6,7[F O H]] to the bones of *synciput*, below to the additament of the nowle-bone by the sixt suture, [Tab.3.fig.9[m n]] to the first bone of the vpper iawe by the fourth common suture. [Tab.2,fig.6[Y]] Each of these hath foure processes. The first is called *Mamillaris*. [Tab.2,fig.6 and 7[X]. Tab.5.fig.8[M]. Fig.9,[x]] The second is called *Styloides*. The third *Labyrinthus*, conteyning the small bones of the eare. The fourth is a parte of the Iugall bone.

CHAP. VI. *Of the two Bones common to the Scul and the vpper Iaw.*

The Wedge-bone.

THE two Bones which belong as well to the vpper iaw as to the scull, are called *Sphenoides* or the Wedge-bone, and *Spongoides* the spongy bone called also *Cribriforme* or *Ethmoides*. The first is set like a Wedge (whence it hath his name) betwixte the bones before described and the bones of the Vpper iaw, so that it toucheth them almost all. In infants it is made of foure bones but after we are growne it also groweth into one entire bone. And becawse it hath many processes and inequalities on both sides, a man can compare it to no one thing, wherfore the Ancients called it πολύμορφον, as if we should say, *Seare-shaped.*

The substance of it is fast and strong, but the inside somewhat spongie. It hath many processes, two on the inside called κλινοειδεῖς, two called πτερυγοειδεῖς like Bats winges, and foure small ones which make the *saddle* or seate.

It hath also many hollownesses or bosomes, some outward in the wingie processes, others inward, in which [Tab.4.fig.10,at C] the Opticke Nerues are ioyned, then the saddle it selfe wherein is the Glandule placed [Tab.4.fig.10,[z]] which receiueth the Phlegme, from whence afterward it floweth into the Palate and the Nostthrils.

It hath also many cauities and ten holes, fiue in the Orbe of the eye, and other fiue in the basis of the Scull. The exact description of all which you must looke for in the booke of Bones.

The Spongie bone.

The second bone common to the Skull and the vpper Iaw is called *Spongoides* or *Ethmoides* Cribre forme; becawse it is full of holes as a Siue or searce, but it may better be called the spongy bone, becawse the holes are not for the most part direct, but crooked and oblique like the pores of a sponge.

It is placed in the forepart of the Skull without the meninges and occupieth almost all the

Tab.5.Fig.12. sheweth the inside of the wedge and spongy bones. Fig.13. Two portions of the bones of the Sinciput a little disioyned the one from the other, that the frame of the Suture might be better perceiued. Fig. 14. sheweth a part of the bone sinciput diuided with a saw from the rest of the same bone, the better to exhibite the substance of the Scull.

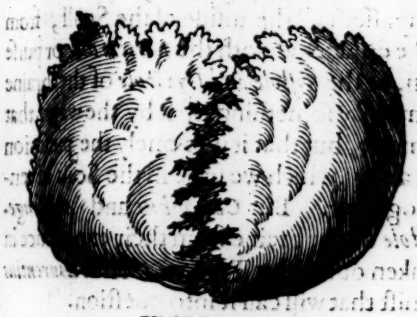
C.D. Two cauities of the wedge bone.
E. A partition distinguishing them asunder.
F. A hole of one of the Cauities ending in the Nostrils.
G. A right Cauity scituated vnder the two former.
H H. Processes like to Bats wings.
a o 14. The vppper or exterior Table *a*, the interiour *o*.
c 14. A cauernouse or spongy substance in the middest betwixt them called *Diploë*.

XIII



XIV.

the cauity of the nose; it is ioyned to the middest of the bottome of the forehead bone, [Tab.4,fig.10,*] and is distinguished from the wedge bone by the a bastard seame called a Harmony, which is accounted for the ninth Suture. [Tab.4,fig.10,aboue ‖] There are foure parts of this bone. The first is an vpper processe in the midst, long & triangular like a Cocks combe. The second is on both sides that processe [Tab.4,fig.10 ‖ ‖. Tab.5,fig.12,^^] which is couered with a thinne Membrane likewise perforated. The third is a lower processe opposite to the vpper which diuideth the vpper part of the nose into two parts. The fourth part is the substance it selfe of the *sponge* from whence it hath his name. The vse of it is to admit aer for the generation of Animall spirits, to admit vapours to the sense of smelling; but the pores of it are not direct but oblique and crooked least the cold ayer should too directly ascend vnto the braine to refrigerate or coole it ouermuch. The vse of it.

CHAP. VII. *Of the Meninges or Membranes of the Braine.*

AS the lower belly and parts therein are compassed with the *Peritonæum*, & the middle with the *Pleura*, so there are two membranes stretched ouer the cauity of the Skull, which *Galen* and those who haue written since his time haue called μηνιγγας. And indeed *Galen* had the name out of *Hippocrates* his book *de Carnibus*, who there taketh it in a larger signification, which giueth *Galen.* *Hippocrates.*

that

Their names.

that name to all parts that are hollow, as the veines, the ſtomacke the guts and ſuch like. *Eraſiſtratus* called theſe membranes ἐπικρανίδας, *Pollux* ἐπαμίδες. The *Arabians* called them *Matres* the Mothers, and ſo now they are commonly tearmed. *Macrobius* calleth them Omenta or kelles. The one of theſe which is the outward is thicke and called *dura mater* the hard Mother, the other inward and thinne called *Pia mater*, the deere or neere Mother, becauſe it immediately incompaſſeth and imbraceth the ſubſtance of the braine.

The *dura mater.*

The thicke *meninx Hippocrates* (in his booke *de locis in homine*) calleth παχυμῆνα. *Galen* σκληρὰ or παχεῖα or δερματώδης μῆνιγξ, that is, the thicke hard or skinny *meninx*, commonly the *dura mater*, becauſe of all the membranes of the body it is the thickeſt, hardeſt and ſtrongeſt, and particularly in relation to the thinner *meninx*.

His figure & magnitude.

In figure and magnitude this membrane anſwereth the bones of the Scull, becauſe it incompaſſeth all his boſomes and cauities. It is greater then the *Pia mater* or thinner *meninx* leaſt if it lay to cloſe vnto it the veſſels that run therin ſhould be compreſſed, which if they be diſtended and ſwell too full of bloud, do cauſe the head-ach yea oftentimes the Apoplexie; whence it is that many which dye of the Apoplexie, auoid bloud out of their noſe and their mouth.

Connexion.

It is tyed very ſtrongly to the Baſis of the Scull and to his ſharper proceſſes, and to the orbes or circles of his holes, [Tab.11, fig.7, zz] whereupon ſome haue thought that from this Baſis it tooke his originall, becauſe ſeede is the matter *out of which* this, as all other membranes are made. Notwithſtanding it cleaueth not ſo cloſe to that boſome of the wedge bone [Tab.4, fig.10ᵗ,] where the Glandule of phelgme is ſcituated, [Tab.7, fig. 15, ^] nor yet at the ſides thereof where thoſe boſomes are which giue way to the branches of the ſleepy arteries called *Carotides*. It incompaſſeth all the inſide of the Scull, from which as alſo from the braine it hangeth in the like diſtance as doth the *Pericardiũ* or purſe from the heart, leaſt the eleuation and depreſsion, or the *Syſtole and Dyaſtole* of the braine ſhould be hindred. I know full well (that we may ſay ſomething of it by the way) that *Platerus* thought that the braine it ſelfe did not moue, but that it was onely the pulſation of the third ventricle much like the beating of an artery, which we feele in the Sculs of tender Infants before their bones are ioyned cloſe together. But *Columbus* and *Archangelus* doe demonſtrate a manifeſt *Syſtole* and *Dyaſtole* of the braine from their experience in thoſe whoſe Sculs are wounded and the bones taken out with a Trepan. And *Laurentius* thinketh him not worthy the name of an Anatomiſt that will call it into queſtion.

Whether the braine mooue or no. *Platerus. Columbus. Archangelus. Laurentius.*

It is tied very ſtrongly to the Scull by thinne and membranous fibres (which *Galen* in the 8. booke of the vſe of parts and the 9. chapter calleth Ligaments) ariſing there-from, which paſſe through the Sutures of the Scull, eſpecially about the Lambdal Suture, euery one of which Ligaments or fibrous ties chuſe you whether, are extended ouer the part of the Scull where againſt they iſſue, and running along are exactly vnited together & make that common Membrane which we ſaide before was called *Pericranium*, vnder which there is yet another farre finer and thinner called *Perioſtium*; from which two membranes all the other membranes of the body haue their origninall, that in this reſpect this *Dura meninx* may well be called *Mater*, as being the Mother of all other membranes. It is alſo knit to the *Pia mater* and to the braine by the mediation of veſſels. [Tab.6, fig.2, ddee. Tab. 11, fig.8, xx.]

It is double but not two.

This membrane is double as are the reſt of the membranes of the body; and *Columbus* makes two membranes of it, one inward another outward, and boaſts himſelfe of the finding of them: whom *Laurentius* cloſely taxeth confeſsing that it is indeed double, but they are not therfore to be called two membranes; ſo ſaith he, we do not ſay that there are two rims of the belly, and yet we know that the *Peritonæum* is double. Well, it hath a double ſuperficies or ſurface; the outward like a broad Tendon is ſtretched ouer the other and groweth vnto it; hard it is and rough, partly by reaſon of the fibres which if you take away a piece of the Scull you may perceiue a little to ſwell vp like a ſmall line, [Tab. 6, fig. 1, ooo. mm. ll.] partly becauſe in the crowne of the head where the ſagitall Suture meeteth with the Coronall, there are certaine ſmal knubs or knots, which in the Scull haue their proper boſomes wherein they couch and to which they grow very faſt. [Tab.6, fig.1, *.]

The inner ſuperficies or ſurface is bright, ſmooth, ſlippery and much whiter without any ſuch knubby or kernelly ſubſtance or fat (what you will call it) at all; moiſtened alſo with a watery humor, [tab.6, fig.2, nn] whereas the vtter is dryer. On the inſide alſo it is of exquiſite ſenſe, but on the outſide not ſo that it might better endure the contaction of the bone

Tab.6. Fig.1. ſheweth a head, the Scull being taken away that ſo the braine may appeare as it is couered with the Dura meninx.

Fig.2. ſheweth the Braine cleared from the Dura meninx, together with the third Sinus thereof, diuided through the middeſt, which is ſhewed couered with the Pia mater.

C C. the beginnings of the veſſels out of the third *Sinus* into the *Pia mater*.
D D D. the propagation or branching of theſe veſſels.
E E E, the *Pia mater* or thin *meninx* immediately compaſsing the braine.
F F F. Certaine veſſels running through the conuolutions or breaches of the braine.
G G G. Certaine branches of veines running through the ſides of the *dura meninx*.
H H H. The thicke membrane reflected downeward.

bone without offence.

It hath many holes or paſſages in it, firſt of all (ſaith *Galen* in his 9. booke of the *vſe of parts*, and the 6. chapter; to giue way to many veines; againe, for the outgate of the Conjugations or paires of the ſinewes. Moreouer in the middeſt it hath one notable perforation and that round, to let out the braine Tunnell, called *Infundibulum*, [tab.12, fig. 11, F] as alſo others at the ſides of the former to admit the ſleepy arteries called *Carotides*, [Tab. 12, fig. 11, c and D] and one larger then all the reſt through which the marrow of the backe deſcendeth out of the braine. [Tab.12, fig.9, N] Finally, where it is ſtretched ouer the ſpongy bone, it is perforated manifold like a Siue. [Tab.14, figure 18, at F and figure 9, at N] His holes or paſſages.

In the top of the head it is redoubled and ſeparateth the braine into two parts, a right and a left, euen as low as the center thereof. [Tab.10, fig. 13, from D to E] Which Reduplication His Reduplication.

plication lyeth all along the third bosome or *Sinus* of this hard membrane & runneth with the bosome through the length of the head forward vnto the top of the nose, and groweth fast vnto the distinction of the mamillary processes, [Tab.9,fig.3,ᴺ] euen as it groweth backward in the middest to the hinder processe.

The Sythe.

This Reduplication of the *dura meninx* is called the vpper processe and is likened by all the best Anatomists to a Mowers Sythe; and *Laurentius* is not affraide to call it *Falx* or the Sythe, and saith that this reduplication makes the body of the same: but *Vesalius* saith that the processe which is like a Sythe is not duplicated but simple as the membrane it selfe is simple, and seemeth onely to be double because of the bosome which parteth the braine; of the same minde also is *Platerus*. But let vs see how it resembleth a Sythe: *Bauhine* fashioneth it thus. Backward, (where it is continuall with a part of the same membrane which couereth the *Cerebellum* or after-braine) it is broad and answereth the broad end of the Sythe, [tab.9,fig.3,at ᴾ] about the midst of his length it groweth to be very thicke like the backe of the Sythe, and the fore end is like the point; for it groweth narrow by degrees and therefore that part of it which is next to the braine turneth inward obliquely iust like the hooking point of a Sythe. [tab.9,fig.3, from ᴾ ᴼ to ᴿ]

The other processe of the *Dura mater* is backward and shorter, and for the most part distinguisheth the *Cerebellum* or after-braine from the braine it selfe, [Tab.11,fig.7, ᵒᵒᵒ] Beside it couereth the *Cerebellum*, and it is foure-fold as thicke and hard as it is in any other place saith *Columbus* and with him *Archangelus* and *Laurentius*, *Vesalius* saith three-folde.

The other processe of the *Dura Meninx.*

A bone in Dogges.

Dogges in this place haue a bone which vnderproppeth the braine that it should not lye heauy or beare vpon the *Cerebellum*. [Tab.11,fig.7, betwixt ᵒᵒ and ˣˣ]

Two kinds of Cauities.

In this membrane there are found two kinds of Canales or pipes; one through which the vessels are carried, as the Arteries which are disseminated through the membrane. The other into which the veines do determine, which kinde of Canale or hollow passage is to it instead of veines; and these they call the backward bosomes, or hollownesses, or canales, (for other words to expresse a *Sinus* I cannot deuise) of which wee will immediately intreate.

Fallopius his ten *Sinus*.

Fallopius in his obseruations reckoneth ten of these *Sinus*, on either side foure; the ninth is that which other Anatomists take for the third, & the tenth that they take for the fourth; but in his institutions he reckoneth but sixe: foure of which we know well, the other two saith *Bauhine*, I thinke no man knowes but himselfe.

Foure *Sinus* of the *Dura mater.*

We with *Bauhine* (whom for the most part we follow) do reckon foure, which *Galen* in the ninth booke *de Anatomicis Administrationibus* called σπλῆνας in the 9. booke *de vsu part.* and the 6. chap. sometimes *meninges* σπληνώδεις leading bloud: sometimes τῆς παχείας μήνιγγος κοιλίας the ventricles of the thicke membrane; as in his 9. booke *de Anatomicis Administrationibus* and the first chapter, because they arise from the duplication of the membrane, and are as it were Rillets carrying bloud and spirits. And haply hence tooke *Pelops* the occasion of his error, who auouched that all the vessels had their originall from the head.

Pelops his error whence.

The two first of these *Sinus* or Canels, or Rillets, (call them as you please) haue their beginning behind in the Basis of the *Occipitium* or nowle betwixt the braine and the after-braine at the sides of the hole through which the marrow of the backe descendeth: they are one on each side, [Tab.7,fig.13,ᴹ ᴺ] called the right and the left. They lye neere the sides of the Lābdall Suture, and into them do the veines and the arteries exonerate & vnburden themselues. They are fastened to the Scull, and when they come neere the middle of the Lābdall Suture & the top of the *Cerebellum*, they ioyne in one and make a common cauity, which place [Tab.7,fig.13,°] *Herophylus* (saith *Galen* in his 9. book of the vse of parts and the 6. chapter, and in the 9. of his Anatomicall Admipistrations and the first) called

The two first. *Sinus.*

Galen.

ληνὸν that is, *Torcular* the *Presse*, because from thence as from a high place the Rils runne downe on eyther side; some of them out of the middest of it are deriued into the whole after-braine, others run from the forepart, from whence, as wine from a grape-presse, the bloud poured out of the veines and arteries is squeesed into the whole braine. From these on eyther hand at the sides runne small branches like veines, some of them as small as a very haire, some of them larger, [Tab.7,fig.13,ˢˢ] which runne out into the bordering membranes, both the thicke one [Tab.11,fig.7, ᵒᵒᵒ] and the thin one [Tab.12,fig.9, ᴮᴰ] where they couer the whole *Cerebellum*.

The Presse of the braine.

Out of the concurrence of these [Tab.7,fig.13,°] do arise two other *Sinus* or Rils differing in length and in the fashion of their cauities. The one of them is the higher and is called

called the third *Sinus* [Table 15. figure 13.[m]] the other lower called the fourth [table 7. fig. 13.[n]]

The third *Sinus* which is like a Rill of bloud, called sometimes by *Galen* a veine and not vnproperly (for what should you call a vessell in which bloud is contained but a veine though it haue not the coate of a veine) though some thinke it to be *Herophilus* his *presse* of which we spake euen now; it passeth directly forward through the length of the head [table 6. fig. 1. and 2. ccc] betwixt the right and the left parts of the Braine vnder the vpper part of the Lambdall Suture and vnder the Sagitall Suture, and vnder the middest of the forehead bone in the top of the nose is ioyned to the bony partition [tab. 7. fig. 13.[o]] of the organs of smelling, and would be like a triangle, sauing that in the vpper part it is some what neere to a *semicircular* form: for the cauity of this *Sinus*, as also of the two former, haue two crooked ribs as it were inward, and the third curued outward. The third.

From this *Sinus* or canale on either side the braine all along the head there arise very thicke certaine vessels as it were branches out of a great trunke of a veine which *Galen* calleth ἐχῖδας, of which some are but small which they call *venas reptitias*, the creeping veines. Of these some arise from the higher part of the *Sinus*, some from the lower, some from the sides thereof. Those which arise out of the higher part [Table 7. figure 13. x x x] which is next the skull, do run vpward to the duplication of the skull, that is to the porie substance between the tables thereof, and to the *Pericranium*, and mingle themselues with those small vessells which descend from the skinne of the crowne and passe through the skull at small pores thrilled therein for the same purpose. Those which arise from the lower part of the canale, that is, which is next the braine [table 7. figure 13. v v v table 9. figure 3.[x x. y y]] are but small, and runne downeward onely into that part of the *dura meninx* which euen nowe we called the *sithe*. Those which arise out of the sides of the *Sinus*, that is out of the bredth of it [table 7. figure 13.[z z z] tab. 8. figure 2.[p p p]] are infinitely diuersified into the *pia mater* and together therewith into the conuolutions of the brain; and where the *pia mater* endeth they proceed on into the very substance it selfe of the braine. These vessels sometimes opening, so great a quantity of bloud hath issued by the Nosethrils, that it is credibly reported to haue amounted to 24. pound: in which kinde of fluxe wee must not apply medicines to the forehead, but either to the crowne or to the coronall suture. Branches frō the 3. Sinus. Great quantity of bloud out of the nose whence it comes.

Columbus was of opinion that these vessels do not arise out of the *Sinus* it selfe, but out of the veines running therin, for he thought that the internal iugular veines passed through it. *Archangelus* also seemeth to incline this way, who sayth that through the two former *Sinus* or rils, the inner iugular veines and arteries doe passe and insinuate themselues into the third *Sinus* and so run out to the nose, yea backward also to the fourth *Sinus* and quite through it. *Columbus Archangelus.*

The fourth *Sinus* sayth *Vesalius* the professors of dissection haue not remembred. It is no where neare vnto the skull as the others are, but seated in the lower part of the braine: very short it is and runneth directly betwixt the brayne and the after-brayne to that part of the braine called *Nates* or the bottocks, and the glandule called *pinealis* (for such representations there are in the substance of the braine [table 7. figure 13.[s] table 11. figure 7.[t]] and the cauity of it is like a triangle made of three equall ribs curued inward. The beginning of this cautiy, or rather trueth to say the meeting of all foure [Tab. 7. fig. 13.[o]] some call the *Torcular* or the presse; and from hence do spring the veines, sayth *Columbus* and with him *Bauhine*, which are dispersed through the substance of the braine to nourish it. The fourth.

From this *Sinus* also in his progresse doe issue small branches, some of which runne vpward to that part of the *dura mater* which is aboue the *Cerebellum* and as far as to the *sithe*, [table 7. figure 13.[yy]] others downward [tab. 7. fig. 13.[aa]] which are dispersed into the *dura mater*, where it lyeth aboue the after-brain, as also into the *pia mater*, both where it compasseth the after-braine and the braine it selfe. Branches frō the 4. Sinus. The vpper.

Afterward this *Sinus* is deuided into diuers rillets; two issue out of the vpper part of it and one out of the lower; of the two which issue out of the vpper part, one is greater another lesse.

The greater [table 7. figure 13.[b]] creepeth along the lower part of the *dura meninx* where it deuideth the braine in his length; from which certaine surcles runne [Table 7. fig. 13.[ccc]] vpward to the processe of the same *dura mater*.

The lesser which is double, a right and a left [table 7. figure 13.[d e] table 3. figure 3.[f f o o]] supported with the thinne membrane after the manner of veines are ledde through the

length of the braine on either side aboue the callous body called *Corpus calosum*, and afford some small twigs to the *piamater* which are distributed on either side into the braine.

The lower rillet [table 7. figure 13.f] is but one propagated into that part of the *pia mater* which compasseth the *Cerebellum*; but it is diuided into two branches, one of them run-

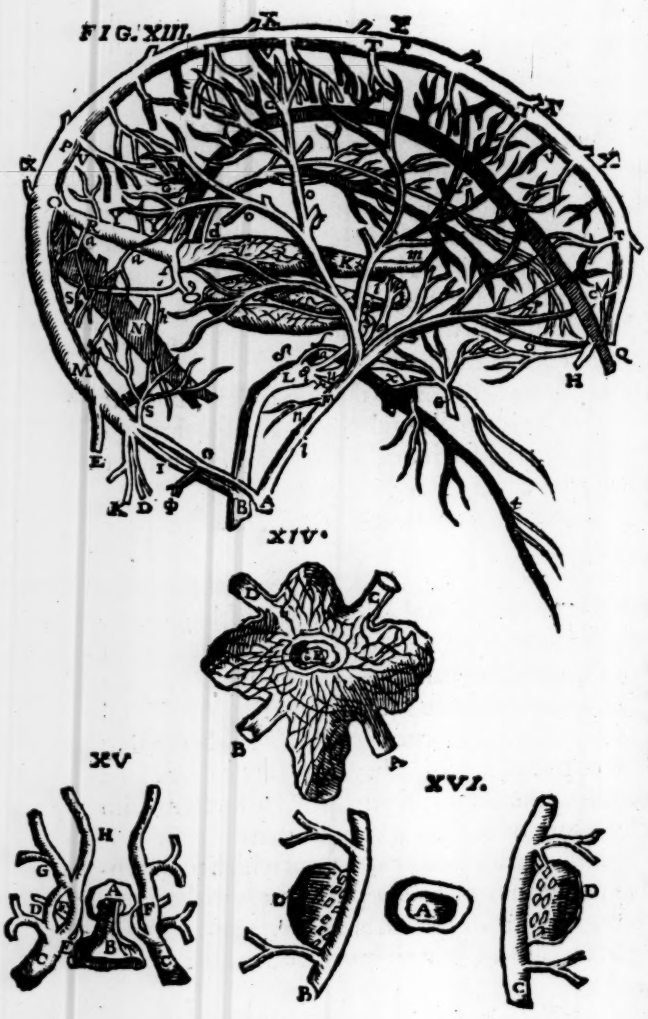
Table. 7. Figure 13. exhibiteth the vessells of the Braine and their distribution, especially through the right side, whither they proceede from the internall Iugular veine, or from the sleepie Arterie, or from the sinus *of the* Dura Meninx.

Figure, 14. *sheweth the wonderful Net as Galen describeth it.*

Figure 15. sheweth the pituitary Glandule with the Bason and the sleepy Arteries.

Figure 16. sheweth the Rete-mirabile *or wonderfull Net, together with the glandule as it is found in the heads of Calues and Oxen.*

TABVLA VII.



A. The internall Iugular veine.
B. The sleepy or Iugular artery.
C. the first veine.
D. the 2 veine which is led vnto the *Sinus*.
E, the 3, creeping through the *dura meninx*
F, the fourth running into the *Sinus*.
G H, the 5 and 6 going to the *dura meninx*.
I, the first Artery.
* A braunch of the same Artery running through the Muscles of the necke.
K, the second artery reching into the *sinus*
L, the third without a companion.
r A small branch of the third Artery.
M, N, the 1 & 2 *sinus* of the *Dura Meninx*.
O, the congresse or meeting of both those *sinus*. PP, the *3 sinus* of the *Dura Meninx*
Q, The end thereof.
R, the fourth *sinus* of the *Dura meninx*.
SS, Branches of the first *Sinus* deriued into the Membranes neere at hand.
TTTT, Branches of the third *Sinus* dispersed into the *Pia Meninx*.
V V, the lower smal branches of the 3. *sinus*
X X, the vpper, distributed through the *Dura meninx*.
Y Y, certain surcles of the 4 *Sinus* sent vpward. *aa*, Others sent downward.
b, the vpper passage of the fourth *Sinus* running by the *Sytb*.
cc, Surcles runing vpward from this passage
de, the right & left vpper branches of the fourth *Sinus*. *f*, The lower branch going to the *Pia mater*.
g, A branch of the same pas. going forward
h, The same bending backeward to the *Choroides* reflected to the *Cerebellum*.
i, A notable vessell into the which the 4. *Sinus* doth determine.
K the vpper. The by-partition of this vessel in the braine.
l, *m*, Two branches of this by-partition.
n. A surcle reching to the organ of hearing
ooo, the distribution of the 3 vein & artery,
ppp, Surcles proceeding from the Brãches marked with *o* deriued into the *pia mater*
q, The diuision of the third artery where it entreth into the scull. *s*. A braunch reaching to the hollownes of the nostrils
t, the end of this in the extreamity of the vessel. *uu*, 2 branches entring into the scul
x. A branch deriued vnto the eie from the coition or meeting of the 3 branches *uu*,
e, A branch attaining to the *pia mater*.
A, A brãch attaining to the right ventricle
* The complication of vessels called *Plexus Choroides* formed on either side of the

branch marked with A. *Fig.* 14, A, B, Arteries climbing into the scull, and making this wonderful net. C D, Branches into which the surcles of that net are ioyned. E, the pituitary glandule or kernel of flegm *Fig*: 15. A, the Glandule receiuing the bason. B, the bason it selfe, or if you wil, the Tunnel called *Peluis* or *infundibulum*. CC, the sleepy Arteries. D, A branch of the artery going to the side of the *Dura Meninx*. E, Another branch of the same artery going to the nostrils. FF, An artery in one side diuided into 2 branches, but in the other side meeting togither againe. G. A partition of the artery creeping through the *dura meninx*, H, Another branch which getteth out of the scull and reacheth to the eies. *Figure* 16, A The petuitary Glandule. B, C. The sleepy Arteries going into the scull. D, D. The wonderfull Net.

neth forward [Tab.7,fig. 13,g] through the Circles of the braine and endeth in the lower ſeate of the ventricle,& is ioyned with an artery aſcending thither [Tab.7,fig.13,y]to make as they ſay that web of veſſels which they cal *Plexus Choroides*, becauſe it is ſomewhat like the after-birth called χοριὸν. The other branch is reflected backeward to the *Cerebellum*[tab 7,fig.13,i] & is diuerſly ſprinkled into his *pia mater*. Finally,and at length this fourth *ſinus* determineth into a notable veſſell couered with the *pia mater* [Ta. 11,fig:7 v.tab:7,fig.13l], which neere the teſticles of the brain,ſo called, is diuerſly diuided and knotted & ſo goeth vnto the Glandule called *Pinealis* aud vnder the arch of the brain called *Fornix* runneth into the inſide of the third ventricle & there is parted into a right branch & a left. The right branch reaching [tab,7,fig.13l,] vnto the right ventricle and the lefte vnto the left, [Tab. 7,fi.13 m]& Anatomiſts do think that they are mingled & ioynd to the branches of the firſt and fourth arteries to make that *plexus choroides* of which we made mention euen now.

Where the 4 *ſinus* endeth.

Theſe *ſinus* or cauities of the *dura meninx* haue not the coats of veins but are in ſubſtance like to the Meninx it ſelfe.For as ſoone as the veine (put caſe the internall iugular) toucheth the ſcul,the *dura meninx* is there preſently duplicated & the inſide becommeth fiſtulated or hollowed like a pipe,& with theſe pipes as if they were veines the veines themſelues are ioyned. They do the office both of veines and arteries, for they beare like arteries ſayth *Platerus*,they receiue into them both veines and arteries (although *Fallopius* thinke they receiue only veines) and the blood and ſpirits of them both. For they are full of blood which they preſerue as they receiue it full of ſpirites, but after death this bloode cloddeth into a grainy ſubſtance, haply becauſe the bloode they receiue out of the veſſels is a little thicker then ordinary ſaith *Bauhine*.They ſend alſo out of themſelues ſcions and ſurcles like to the branches of Veines which paſſe vnto the Braine and both the Meninges.

The matter of theſe *ſinus*.

They doe the office of veins and arteries.

For becauſe the Braine is large and ſtandeth in neede of a great quantity of blood, but yet cannot admit any notable branches of Veines and Arteries to runne thorough his ſubſtance, Nature made theſe *ſinus* or rillets to be in ſtead of veines and arteries to paſſe thorough and irrigate or water the whole ſubſtance thereof: for into them there is continually powred great abundance of blood which is mingled, the Venall I meane with the Arteriall, and afterward conneyed by theſe pipes vnto the conuolutions of the Brain,yea into his very ſubſtance,aſwel for his nouriſhment and life as alſo for the generation of the Animal ſpirits which are wrought within his ſubſtance.For ſeeing theſe Animall ſpirits are continually ſupplyed vnto the inſtruments of ſenſe and motion,and by motion are ſpent & diſsipated, it was neceſſary there ſhould be great quantity of both kinds of bloode in this place mingled together to make ſupply of them.

why the brain needeth much blood.

The vſe of the *Dura Meninx* is,to hold together the whole ſubſtance of the Brain and be a couering thereunto and to all the parts of it, for it compaſſeth about the ſpinall marrow alſo,yea and all the Nerues that yſſue out of the Braine. It alſo defendeth the brain from the impreſſions of the Scull or compreſsions if by any outward iniury it be beaten downward. It alſo preſerueth the Arteries which runne in the ſurface of the Brain,that in their *Diaſtole* they be not offended by the hardneſſe of the Scull.

The vſe of the *Dura Mater*.

Moreouer, it diuideth the Braine from the after-braine or *Cerebellum*,as alſo the braine it ſelf into a right part & a left. Finally,it produceth Ligaments through the ſutures of the ſcull to make the *Pericranium* and to faſten it to the ſcull, that it might not ſinke downe toward the braine, as alſo to hold vp the braine it ſelfe leaſt ſetling down it ſhould compreſſe the Ventricles which would cauſe ſudden death. And thus much concerning the *dura mater* or *Meninx*, wherein we haue beene ſomewhat prolixe, that nothing might eſcape worthy your obſeruation.Now it followeth that we entreate of the *Pia Mater* or thin *Meninx*.

The *Pia mater* or *tenuis Meninx*.

The *Dura mater* being taken away we meete with the ſecond Membrane called *Pia mater*, delineated vnto you in the ſixt Table and the ſecond Figure, but in the ninth Table & the third Figure ** ſheweth the *Dura Mater* and °° the *Pia Mater* of which we now ſpeake.This Membrane euen conſidered of it ſelfe, as alſo in compariſon with the other Membranes of the body is exceeding thin, and therefore called λεπτὴ μηνιγξ by *Galen* in his ninth booke *de Adminiſtrationibus Anatomicis* and the ſecond Chapter. The name he had out of *Hippocrates* his Booke of the Falling ſickneſſe,where he ſaith that this λεπτὴ μηνιγξ diuideth the middle of the Braine,or the Braine in the middeſt.*Galen* alſo in his eight Booke of the vſe of parts and the ninth chapter calleth it μηνιγξ χοριοειδὴς,that is the Membrane like the *ſecundine* or after birth,becauſe it conteyneth or holdeth faſt the veins and arteries of the brain, leaſt whilſt they mooue they ſhould be diſplaced,their baſis or foundation being but weak and infirme.

His Names.

His figure. Magnitude. This membrane is for the moſt part conteyned within the skull immediatly couering the brain and there is iuſt of his figure. In magnitude anſwerable to the braine & the parts thereof; but the ſubſtance or body of it is exceeding thinne and fine, and yet *Cabrolius* and *Laurentius* ſay it is doub'e. Subſtance. It is thinne that it might more eaſily inſinuate it ſelfe into the conuolutions of the braine, and yet not be offenſiue by the waight of it to the brayne vpon which it lieth, and beſide to carry the veſſell quite through the ſame [tab. 6. fig. 2. ᵇ ᵇ table 9. figure 3. ᵒᵒ.] It is ſoft and of exquiſite ſence becauſe it communicateth the Tactiue vertue to the Brayne and the Nerues; and *Archangelus* ſayeth it is the very inſtrument of *Touching*.

The counſel of Nature. This Nature placed betweene the brayne and the *dura meninx*, leaſt the braine ſayth *Galen* in his 8. booke of the *Vſe of parts* and the 9. Chapter ſhould be offended by ſo hard a neighbour. For euen as ſayth *Plato* betweene the earth and the fire becauſe their natures are very contrary, God interpoſed the water and the ayre, ſo *Galen* ſayeth that Nature betwixt the brayn and the skull which are partes of very different ſubſtance hath placed theſe 2. membranes or minniges. For if there had been none but this thin *pia mater* it could not haue agreed with the skull without offence, if there had beene none but the *dura meninx*, yet the braine would haue beene therewith offended. That therefore neither the braine nor his couer ſhould endure any vncouth violence, Nature hath immediately couered the Braine with this *pia mater*; and then the *pia mater* hath ſhe compaſſed with the thicker; for by how much the thicker is ſofter then the bone, by ſo much is the braine ſofter then the thinner.

If you would know what diſtance there is betweene theſe two membranes, you muſt make a little hole in the thicker, and then put a hollow bugle to it and blow it and you ſhal perceiue that the diſtance between them will containe a great deale of ayre, by which you may imagine how farre they were ſeuered when the man was aliue.

The progreſſe of it. This membrane doth not onely cleaue cloſely to the braine and couer it immediatly as his naturall coate, as a mother embraceth her infant (whence *Platerus* thinketh it was called *pia mater*) leaſt the ſoft and moyſt ſubſtance thereof ſhould be ſeuered by the continual motion wherwith it is wrought vp and down (for we perceiue that the brain wil eaſily run abroad when it is taken away) but alſo it inſinuateth it ſelfe into the bottome of the braine, and extendeth it ſelfe vnto the inſide of the cauity of his ventricles ſaith *Galen* in his 8. book of the *Vſe of parts* and the 8. chapter, lining them round within. The vulgar Anatomiſtes ſayth *Laurentius* thinke that it paſſeth into the ventricles from the vpper part of the brayn; but the truth is that it aſcendeth from below where the *Infundibulum* or Tunnel of the brain is ſcituate, and where thoſe ſmall arteries deriued from the ſleepy arteries called *Carotides* do paſſe into the brain at the ſides of the wedge-bone; ſo that euen in the bottom it meeteth; without the skull it cloatheth the marrow of the backe and the nerues. The bones alſo ſayth *Archangelus* doe ſeeme to bee couered with this thinne membrane, which nowe hauing with his vſe changed his name is called *Perioſtium*. But how it maketh the *Infundibulum* or Tunnell called alſo *Peluis* the Baſon, and how it inueſteth the vpper part of the phlegme-glandule, we ſhall declare afterward. *Archangelus.*

The vſe of the *pia mater*. The Vſe of it is, to couer and eſtabliſh the braine, the after-brain, the marrow of the ſpine and the nerues, as alſo all the veſſelles which runne through it, it knitteth together, ſo that they are more ſafely and commodiouſly diſtributed through the whole body of the Brayne and through all his partes. Adde hereto that which *Archangelus* determineth in the firſt Booke of his Anatomy, that it is the moſt exquiſite and proper inſtrument of the ſence of *Touching*.

CHAP. VIII. *Of the veſſels diſſeminated through the Brayne.*

THE veſſels diſſeminated through the Braine are Veines and Arteries and thoſe *Sinus* or Canalles whereof wee intreated at large in the former Chapter.

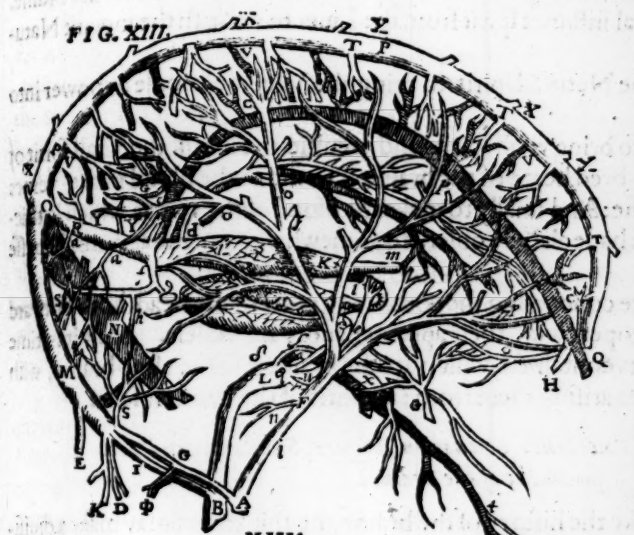
The veines. The Veines are braunches of the inner or vtter Iugulars: the Arteries of the *Carotides* or ſleepy Arteries, and of that we call *Ceruicales* or the artery of the necke.

The inner iugular. The inner Iugular at the Baſis of the skull in the backpart [table 7. figure 13. at ᴬ] is deuided into two bráches, one bigger which watereth the backpart, & another ſmaller branching

ching forward. The bigger [Tab.7,fig.13, the lower [c]] attaineth into the braine at the firſt hole of thr Nowle-bone.[Tab.4,fig.10,[b]] The leſſer,[Tab.6,fig.1,[pp]] getteth into the braine at the ſeauenth hole of the wedge-bone. [Tab.4,fig.10,[x]]

The vtter Iugular veine ſendeth three branches into the Scull: the firſt [Tab.7, fig.13,[s]] entreth into the *Sinus* of the *dura meninx* through the hole of the temple bones. [Tab.4, fig.10,[c]] The ſecond [Tab.7, fig.13,[c]. Tab.14, fig.19,[hh]] paſſeth in at the ſecond hole of the wedge bone.[Tab 4,fig.10.[g]] The third [Tab.7,fig.13,[k]. Tab.14, fig·19,[ll]] is diſtributed into the *dura meninx*, and getteth in at the hole of the ſpongy bone. The vtter Iugular.

FIG. XIII.



XIV.

XV

XVI.

Beſide theſe fiue veins, *Veſalius* and *Platerus* add another, to wit, the end of the Necke veine which entreth the Scul (ſay they) at the third hole of the Nowle bone which was purpoſely made for it. But *Bauhine* could neuer obſerue it; yet wee haue added it in the Table. [Tab.7,fig.13,[p].] Thus much of the veins, now of the arteries. Another vein of *Veſalius* his finding. The arteries.

The ſleepy artery called Carotis whē it is come on either ſide to the Chops is diuided into two branches, one exterior of which heereafter, the other interior which is the larger of the twain. This at the Baſis of the Scull [tab. 7,fig.13,[x]] is diuided into 2. vnæquall branches. The firſt is a little leſſe then the Trunke, [tab.7,fig.13,[ll].fig.15,[ee]. tab. 14,fig.19,[p]] piercеth the Scull through a proper hole of his owne thrilled in the temple-bone, paſſeth vnto the ſaddle of the wedge bone and then ſheaddeth a branch on each hand into the ſide of the *dura mater*, [tab 7,fig.15,[d]] and afterward being diuerſly carried and diuided (as wee ſhall heare more diſtinctly in the booke of veines) it helpeth to make the *Rete mirabile*. [tab.7,fig.14] and the Plexus Choroides. The firſt.

From this firſt iſſueth a branch obliquely, [tab. 7,fig. 13,[q]] and getteth into the braine at the ſecond hole of the temple-bone, and then is diuided into two branches, the one running outward [tab.7, fig.13,[r]] through the eight hole of the wedgebone into the cauity of the Noſe: [tab.7,fig. 15,[r]] the other inward, which is diuided into two, [tab.7,fig.13,[uu]] and after diſtributed into the Dura Meninx; and this is called the ſecond artery, though it ariſe out of the firſt. The ſecond.

The third artery [Tab.7,fig.13,[t]] is the other branch of the inner trunke of the Carotis, much leſſe then the firſt; getteth in at the firſt hole of the nowle-bone, [Tab.4,fig.10,[b]] and ſo paſſeth into the *Sinus* of the *dura meninx*. The third.

There is alſo one other artery called *Cerui calis* which is a ſprout of the axillary artery, it perforateth the *dura meninx* in the ſide where it inueſteth the ſpinall marrow and entreth the Scull at the ſame large hole whereout the marrow iſſueth, and aſcendeth vnto the place of the Glandule called *pituitaria* where it is diuided into two branches, which helpe to accompliſh the Plexus Choroides. A fourth.

Beſide

The *Sinus* of the *Dura meninx*.

Beside these veines and arteries; the *Sinus* of the *dura meninx* is also a vessell of the braine which we haue at large discribed before. It receiueth three veines, [Tab. 7, fig. 13, $^{c\,p\,r}$] and two arteries [$^{t\,x}$] which vnburthen themselues into it: and this *Sinus* according to his diuers course is distinguished into foure as you haue heard, which are larger then the veines that ascend vnto the Scull but not round as they are, but rather like a triangle consisting of three ribs of an equall length and curued somewhat inward. From these do issue certaine passages like vnto veines; by which both sorts of bloud Naturall and Vitall, is distributed into the substance of the braine as we haue said before.

The vse of the veines.

The vse of the veines is three-fold, first to bring plentifull nourishment to the braine. The second, to bring a Natural influent spirit from the Liuer to nourish the ingenit Naturall spirit of the braine.

The third, together with the Naturall spirit to bring the Vegetable soule or power into the braine.

The vse of the Arteries.

The vse of the arteries is to bring vitall spirits and facultie to cherish the vitall spirit of the braine, to ventilate the in-bred heate of the braine, to moue the bloud in the veines which otherwise would putrifie: And finally to make the bloud of the veines which is thicker heere then ordinary as we haue already obserued, somewhat thinner that it might passe and repasse more freely.

And thus much shall suffice concerning the containing parts of the head both outward and inward, common and proper, with their appurtenances the vessels. Now it is time we should come vnto the parts contained, which are the braine and the after-braine, with the spinall marrow and Nerues arising there from: and first of the braine it selfe.

CHAP. IX. *Of the Excellency, Scituation, Figure, Substance, and Temperament of the Braine.*

A diuision of the Head.

BEing to vndertake the history of the braine, me thinkes we may make a diuision of those parts that belong vnto & fall vnder our sense into foure sorts. One sort of them that are about the braine as the containing parts already spoken of outward and inward, common and proper. Another sort of them that are within the braine as the substance thereof, the figure, the magnitude and the diuers parts which haue diuers names giuen them according to their different formes, of which we will heere and heereafter intreate. A third sort of them that ascend vnto the braine, as the veines and arteries, of which we spake somewhat in the former chapter, and shall do more if God permit in the booke of vessels. A fourth and last sort of them which issue from the braine as the marrow of the backe or spine, the Nerues and the Animall spirit of which also we shall presently heereafter discourse: But to the purpose.

Aristotle.

Aristotle (in his 2. booke *de partibus Anamalium* and the 7. chapter, and in the first book of his History of Creatures, and the 16. chapter) saith, that all Creatures which haue bloud, haue also a braine and none other, vnlesse it be somewhat proportionable as the *Polipus*.

This braine among the auncient *Greekes* had no proper name, but because of the scituation it was called ἐγκέφαλος because it was contained ἐν τῇ κεφαλῇ in the head. Of the generation of it *Hippocrates* hath learnedly discoursed in his booke *de Carnibus* to which we referre the learned Reader; as also for the order of the generation thereof to *Aristotle* in his booke *de generatione Animalium* and the sixt Section.

The braine the principall part of the whole body, and why.

It is the principall part of the whole body which may be proued by the scituation, the figure, the defences it hath, and the vse of it. The scituation is in the highest part of the body as it were in a defenced Tower, that it might bee better secured from outward iniuries.

The figure is round, which is the most noble figure of all the rest, for it was proportionable that the diuinest part should haue the most perfect and absolute figure.

The defences of the braine.

The defences of the braine are very many, the haire, the skinne and that the thickest of all the body, the fatte, the fleshy Membrane, the *Pericranium*, the *Periostium*, a double tabled Scull and two Meninges or membranes, by all which it is of all sides defenced from violence, so that it cannot be hurt or offended but with extreame wrong. But neyther the heart nor any other part is so prouided for by Nature, wherefore it should seeme she made more of itore, as we say, of it then of all the rest.

The excellency of the vse of it.

In respect of the vse it will easily carry away the prize of Excellency; for the soule of

of man saith *Varolius*, being not tyed to any bodily instrument cannot apprehend those outward things which are without it selfe, vnlesse it be by the mediation of a corporeall organ into which the *species* or formes of materiall things may be transmitted by which afterward they may be exhibited, and in which they may be apprehended and contemplated: euen as he that is shut vp in a roome, cannot see those things which are, or are acted without, vnlesse there be some Tralucent body wherin the Images of those outward things may first be receiued and after represented to him that is within. Such an instrument is that which wee call *Commune sensorium* the common sence; for nothing can come into the vnderstanding vnlesse it be first in the sence. Comparison.

Now this first or common sense according to *Plato* and *Galen* is the braine; (for *Aristotle* did but dreame that it was the heart) and they thought well. For not onely *Galen* but *Aristotle* himselfe did resolue that that was the first *Sensorium* or common sence, which is the originall of sinewes. Nowe Anatomy teacheth vs that all the sinewes arise from the braine. *Arist.* dreame. The common sence is the braine.

Hence then it is manifest that the Braine is the seate of the Sensatiue Soule; for if a nerue which is directed vnto any part be obstructed, that part is depriued of sence and motion & so of the sensatiue Soule. If the originall or beginning of the spinall marrow be obstructed all the parts vnder the head doe loose both sence and motion, when as yet the head enioyeth them both. But if the fourth ventricle of the Braine be obstructed, then not onely the whole bodie but the head it selfe looseth motion and sence, and is depriued of the sensatiue Soule.

Who then will deny that the Brayne is the most noble of all the members, seeing it is the seate of all the Animall faculties, Imagination, Reason or discourse & Memory (wherfore *Aphrodisæus* called it ὄργανον τοῦ φρονεῖντος *The Organ of wisedome*) and the beginning or originall of sence and voluntary motion; and beside seeing from it doe issue and on it do depend all the instruments of the senses of seeing, hearing, smelling, tasting, touching yea and speech also. And therefore *Plato* did worthily call it, because hee could giue it no higher a stile, *The deuine Member*. For what the Heauen is in the worlde, the same in man is the Braine. The Heauen is the habitation of the supreame *Inteligence*, that is of God; and the Braine the seate of the *Soule*, that is the *demi-God* of this *Little-world*. *Aphrodisæus*. *Plato*.

Hence it was that *Homer* called it ὄρανον, that is the *Heauen*, because as from the Cœlestiall influence all things below it are moued both in heauen and earth; so all the parts of the body haue sense and motion from the influence of the Braine. Comparison

Wherefore with *Galen* we determine that the Braine as well as the Heart is a Principall part: not that wee think, as some doe, that the Braine is the Prince and King of all the rest, no more then we thinke with *Aristotle* that the Heart is the most noble of all the parts. But we say that as the heart is of greatest and most instant necessity for life, so the place of dignity belongeth to the Braine. *Columbus* giueth an elegant reason hereof taken from Generation. The braine not the prince but a principal part. *Columbus* his reason.

The Liuer sayth hee is ingendred by the mediation and helpe of the vmbilicall veine, the heart by the mediation and helpe of the vmbilicall arteries, and these are ingendred by the vessels of the wombe: but the nerues which are the instruments of sence and motion doe immediatly arise out of the braine of the Infant.

The Braine is commonly called ἐγκέφαλος. *Galen* in his Book *de motu musculorum*, calleth it μυελὸς ἐγκεφαλίτης *The marrow of the head*, for a differencee betweene it and the marrow of the backe which is called ῥαχίτης, and the marrow of the bones from which it much differeth, because it is not dissolued by fire, nor consumed in hunger, nor contained in the skull to nourish it. Wherefore *Galen* in his 8. Booke *de vsu partium* and the 4. Chapter putteth a difference betweene it and the marrow of the bones, because this is fluxible and like vnto fat, neither couered with coates nor wouen with veines and arteries, neither hath any communion with the muscles and nerues, all which is contrary in the Braine. The name of the braine.

Apollidorus thought that none of the Antients had giuen any name to the Brain in any of their writings, and that therefore *Sophocles* called it λευκὸν μυελὸν, the white marrow; imitating therein *Plato*, who when he would giue a name to the Brayne called it μυελὸν, and True Loue the Grecians say is ἐς ἄκρον μυελὸν ψυχῆς, *euen at the vppermost marrow or at the Braine of the Soule*, no doubt because they thought that the Soule was in the Braine. *Sophocles*. A greeke phrayse.

It is scituate in the head as in a Castle most safe, because of the defences thereof before mentioned; as also because it is the highest place, & as it were the Tribunall or throne

of

of her body. For as God who is the parent yea the Creator of the Vniuerſe is ſaid to haue his ſeate and throne in heauen. So the Braine which is the pallace of the ſoule was wiſelie ſeated in the height of the body, partly becauſe of the eyes and eares, for their nerues being ſoft had needе alſo be as ſhort as might be, and therefore placed neere vnto the brain. Now aboue they muſt neceſſarily be ſeated becauſe they are the ſcout-watches of the Bodie to foreſee and to heare of dangers before they come vpon vs.

Figure. The Figure of the Braine is anſwereable to the Figure of the Scull, not that it is faſhioned by the Scull, for if it had beene ſo, then the Scull ſhoulde haue bin formed before the Braine. Againe (ſaith *Galen* in his 8 Booke of the vſe of parts and the 12 chapter) they that ſay that the Braine is faſhioned by the Scull do not obſerue that the Brain is manifeſtly ſeparated from the *Dura Meninx*, and that the Meninx it ſelfe although it touch the ſcul yet it adhereth not vnto it. It expreſſeth indeede in the ſurface of it the forme of the cauitie of the ſcull, and when it is rightly formed it is round and a little longer then globous, becauſe of the ventricles which were to be formed therein.

Forward it is ſomewhat narrower, backward broader and on either ſide lightly depreſſed [Tab.6, fig.2 ſheweth this] but in thoſe that haue as we ſay *Laſa principia*, that is, in Ideots it is often otherwiſe faſhioned as we haue ſaid before. But in the Baſis it is vnequal & full of variety becauſe the ſcull hath there diuers dens and boſoms, eſpecially at the wedge-bone [Tab.14, fig.19 betweene ^ and the latter ^B] and the inward proceſſe of the Temple-bones. [Tab.15, fig.20, betweene H and N] But aboue all it ſwelleth out forward at the inſtruments of ſmelling, and produceth two *teates* as it were [Table:14, fig:19, cc] vvhich are therefore commonly named *Mamillares proceſſus*. But where it coucheth vpon the *Cerebellum* or after-braine it is ſmooth and more equall. [Tab.14, fig.18, AA, BB]

Magnitude. *Ariſtotle.* Concerning the magnitude, the braine of a man (ſaith *Ariſtotle* in his 2 Booke *de partibus Animalium* and the 7 chapter in compariſon and proportion with other creatures is the largeſt, ſo that the Braine of one man is more then three Oxen, firſt becauſe in man there are many Animall functions which beaſts haue not, and thoſe that we haue common with beaſts are in vs much more perfect. For being in man the inſtrument and organ of reaſon, it was neceſſary it ſhould conteine yea and perfect alſo great plenty of ſpirits. Now many ſpirits cannot be made but of much blood, and aboundance of blood cannot be contayned in a little body. Againe, it was fit that the braine ſhould be large, moiſt, thick & glutinous that they might not by reaſon of their notable tennity vaniſh away but paſſe into the whole body by proper and peculiar chanels framed for them.

But the magnitude in length, bredth and thickneſſe is ſo great as the capacity of the ſcul is able to conteine, for together with his Membranes the Flegmaticke Glandule and the veſſels that aſcend vnto it; it filleth al his compaſſe [Tab.6.fig.1 and 2. Table.9. fig.3 and 4] before and behind, and on either ſide, only leauing ſo much diſtance as may ſuffice for his *Diaſtole* and *Syſtole*. Finally, it is ſo great ſaith *Bauhine* that in our diſſections we haue found it weigh foure or fiue pounds; and *Archangelus* addeth fiue pound and a halfe; for the larger a man is the greater and more weighty is his braine, yea children becauſe of the waight of their braine cannot of a long time carry their heads ſteddy vpon their ſhoulders.

Connexion. It is knit by a common connexion of Veines, Arteries and Sinnewes with the reſt of the parts, although more familiarly to the ſpinall marrowe and the ſinnewes, becauſe they are produced heere-from. Hence it is, that when the leaſt or baſeſt part of the body is pained the Braine alſo partaketh of the ſmart. As for ſupportation and ſtrength it needed no aſſiſtance from the other parts becauſe it is ſo ſtrongly fortified and as it were intrenched with in the ſcull.

Subſtance. *Archangelus* *Praxagoras.* *Philotimus.* The ſubſtance of the braine hath a double principle of which it is formed, the ſeede and the Mothers blood. *Archangelus* thinketh it hath no ſuch principle, it may be he is of the opinion of *Praxagoras* and *Philotimus* of whom *Galen* maketh mention in his 8 book of the vſe of parts and the 12 chapter, who thought that the braine was nothing elſe but a production or propagation of the ſpinall marrow, and that was the reaſon why it is foulded vp in ſo many convolutions and revolutions. But this is an idle ſpeculation of a vvandering Brain. We wil determine as is ſaide that it hath a double principle ſeed and blood, of which is generated a peculiar kinde of glandulous ſubſtance like whereunto there is none in the whole body, ſo that *Ariſtotle* exceeding well in his 2. Booke *de partibus Animalium* and the 7 chapter ſaide, that it was *ſui generis* of his owne kinde, intimating thereby, that there vvas no other kinde in the whole body whereunto it might fitly be referred. For becauſe the in-

Ariſtotle.

genit

genit functions of the Braine are peculiar vnto it alone as *Vesalius* hath well obserued, it was framed and fitted by Nature for the performance of those functions, of a peculiar substance and essentiall forme wherein the principall faculties of the soule, Iudgement, Imagination, Reason and Memory might reside, and which they might vse as their proper instrument, and on which the rest of the senses might depend. *Vesalius*

It is white, soft and very moist. White by reason of his spermaticall matter, for it is made of the purest part of the seed furnished with abundance of spirits, as also that the Animall spirits therein conteined should be cleare and bright, not muddy or otherwise coloured. Yet is not all his substance perfectly white, for that which is neerest to the convolutions [Tab.9.fig.4. Ta.10,fig.5 ¹²] is somwhat neerer to an Ash colour, as it is also in the *Cerebellum*; the reason whereof some thinke to be because there are so many small veines disseminated through it. For as we thinke the *via lactea* or Milky Way in heauen is occasioned by an infinite number of small starres which to vs are inuisible, but yet do giue a brightnes to that part of the sky; so though we cannot see how the veines do alter the colour in this place, yet seeing it is altered, it is very reasonable that the insensible membranes of the small veines giue that ashie colour vnto it. The rest of the Braine a little more inward is pure white [Tab.9.fig.4, ⁶ⁿ. Tab.10,fig.5, ⁰ⁿ. Tab.11,fig.7 and 8, ²²] why the brain is white. Comparison.

It is soft, and softer saith *Galen* in his 8. Booke *de vsu partium* and the sixt Chapter then the *Cerebellum*, because it is the originall of the soft Nerues pertaining to the Organes of sense, but the *Cerebellum* is the originall of the hard Nerues commonly thought to bee the Nerues of motion. In Children the Braine is so soft that it is fluid. The reason of the softnesse is because it is to receiue all the species or representations of the outward senses, as also of the imagination and vnderstanding. For vnlesse the alteration or impression that is made in any of the senses do proceede first from the Braine and after returne againe vnto it, the creature hath sence of nothing; which is proued by the example of such as are taken with the Apoplexie. Wherfore seeing sensation is a passion, it was requisit that the braine should be of such a substance as is fit to receiue the impressions of other things. Yet it behooued not it should be so soft as that the impresions made therein, should presently sink away and be obliterated, as it hapneth in water and other fluide bodies, but that it should haue with the softnes a kind of consistence or solidity, which solidity is so exquisitely mingled with the softnes, that the fire cannot melt it as it doeth fat or wax and such like. To conclude it is like the substance of a nerue, of which also his marrow is the originall, but a little softer: *Hippocrates* in his booke *de Glandulis* likneth it vnto a kernell, because as a kernel it is white and friable, and beside is of the same vse to the head that a glandule would bee, drawing vp the exhalations of the lower partes which after vapour out by the Sutures of the skull. Why soft. Why not like to Fat. Why it melteth not.

The Temperament of the brayne is cold and moyst, as wee may easily with *Galen* in the 8. booke of the *Vse of parts* conclude from the softnes and moystnes of his substance. Wherfore *Hippocrates* in his book *de Carnibus*, calleth it μητρόπολιν τῦ ψυχρῦ καὶ τῦ κολλωδέος *the Metropolis* or chiefe seate of cold and glutinous moisture. Glutinous to hold and conteine the subtile Animall spirits which otherwise would soone vanish and decay; and colde that the part ordained for the exercise of reason and therefore fulfilled with hot spirits should not easily be set on fire or enflamed. For when the braine by any accident or distemper growes hot as we see in phreniticall patients, the motions thereof are furious and raging, and the sleepe turbulent and vnquiet. And indeede the Heade is verie subiect (colde although it be by nature) to hot distempers, partly because of the perpetuall motion thereof and of the spirits, partly by reason of the aboundant Veines and Arteries and great quantity of blood therein conteyned, and finally because whatsoeuer hot thing is in the body either naturall or vnnaturall if it be inordinately mooued flieth vp vnto the braine, or at lest sendeth hot vapors vnto it. The temperament of the Braine. The Reason thereof.

CHAP. X. *Of the Substance & parts of the Braine.*

AS the Braine is the Originall and seate of all the Animall Facuties, so for the exercise of the same it hath diuerse and different parts cast into sundry moulds which we will now take view of according to Anatomicall Method, alwayes remembring that by the Braine wee vnderstande whatsoeuer is conteyned within the Scull and compassed about by the hard and thin Membranes. why the brain hath diuerse parts.

The

3 Parts. The Braine therefore wee deuide into three parts. For first it is parted into a forepart and a hinde-part by the *dura meninx quadruplicated* or foure-foulded.

The forepart. The forepart because it is the greater and most principall (for in it the Animall spirites are especially laboured) reteineth the name of the whole, and is properly called *Cerebrum* or ἐγκέφαλος. The hinder part is much lesser, and is called by a diminitiue word, *Cerebellum* we call it the After-braine. *Herophilus* as *Galen* witnesseth in his 8. book of the *Vse of parts*, and the 11. Chapter, calleth it παρεγκέφαλις.

Subdiuided. Againe the forepart or the Braine, by the *dura meninx* duplicated and resembling a Mowers Sythe, is parted in the top throughout his whole length into two equall parts, one right another left. [tab. 8. fig. 2. from ^ to ^ tab. 9. fig. 3. from ᴺ to ᴺ.]

This partition reacheth altogether to the Center of the Braine and stayeth at that body which we call *Corpus callosum*. [table 9. figure 3. at ᴸ ᴸ.] And this is the reason why alwayes the same part of the head is not pained, but sometimes one part sometimes another, sometimes the whole head.

Some, sayth *Laurentius*, haue dreamed that the braine is deuided quite through, but they are much deceiued, for the callous body vniteth the parts together. As for the after-braine though it bee not vnited to the braine, yet is it in two places continued with the beginning of the spinall marrow, and the same marrow by two originalles ioyned vnto the Braine.

The vse of this diuision Out of *Vesalius*. The vse of the diuision of the Braine is first out of *Vesalius* and *Archangelus*, that the braine might be better nourished, for by this meanes the thinne membrane together with the vesselles there-through conuayed, doe insinuate themselues deeper into the substance thereof: for without this partition and those deepe conuolutions which wee see in it when it is cut, it could not haue beene nourished.

Out of *Laurentius*. The second vse wee will adde out of *Laurentius*, to wit, beside the nourishment for the better motion of the same; for as water is not so easily moued where it is deep as where it is shallow; so if the braine had beene one entire massie substance, it would not so willingly and gladly as we say, haue risen and falne in the *Systole* and *Diastole*.

Out of *Bauhine*. The vse of this diuision out of *Bauhine* is more expresse: for the safe conduct of the *sinus* or pipes of the hard *meninx* mentioned in the seauenth Chapter, from whence doe issue small surcles of vessels to conuay nourishment into the conuolutions of the braine.

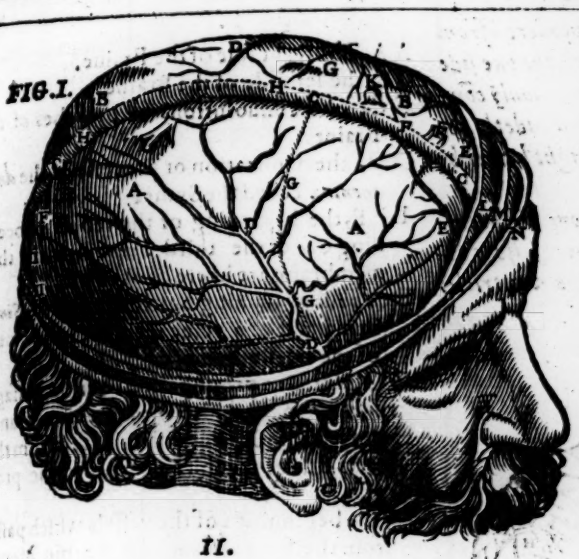
For because the quantity of the braine is very great, through which the *Capillarie* vessels were to be dispersed for his nourishment; if the vesselles themselues so small as they are veines and arteries, should haue passed from the backepart to the forepart, from the right side to the left, or on the contrary, they would in so long a iourney through so soft and clâmy a body haue beene in danger of breaking, wherefore the braine was deuided into three parts; betweene which diuisions there runne foure *Sinus* or pipes of the hard *meninx* into which the internall Iugular veines and the sleepy arteries called *Carotides* ascending from the Basis of the Nowle of the head doe powre their bloud and spirits; which is conuayed on either hand into the after-braine and the brain, by certaine branches deriued out of the height and depth & the sides of those pipes as we sayd ere-while, especially out of the third *Sinus*, into the left and right parts of the braine.

Finally, because soft bodies when they are great doe easily fall into themselues, therefore the braine was diuided into two partes that it might the better consist, as also that the instruments and organs which were led vnto it might not be shufled together: and somuch of the vses of the diuision of the braine.

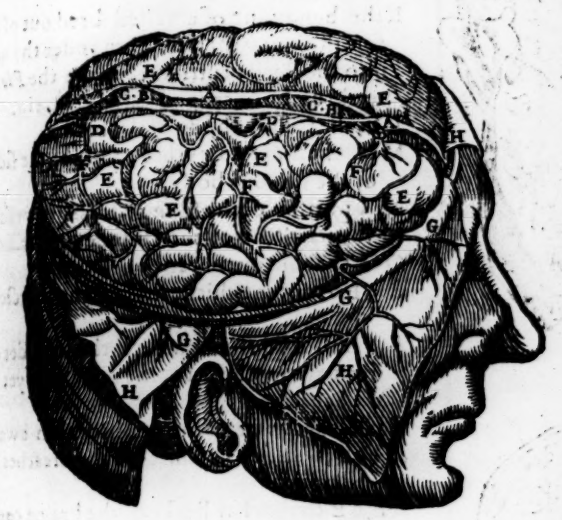
The conuolutions of the braine. Now the outward face of the braine which we sayed was of an Ash-colour rather then white, hath many and diuers orbicular circumuolutions and circular ruts, which the Antients sayeth *Vesalius* and those after him haue excellently compared to the gired windinges of the guts when the kell is taken off. [Table 8. figure 2. tab. 9. figure 3. c c c.] *Galen* in his 8. booke of the *Vse of partes* and the 13. Chapter calleth this *variam compositionem*, and *Vesalius* himselfe compareth them to the Clouds that a Painter maks in the roofe of a house. Some of these snailing paths are deeper, others do not pierce so deep into the substance of the braine [Table 9. figure 4. ᴰᴰ] and therefore are called *pars varicosa cerebri*, the knotted or embossed part of the braine by *Laurentius*. They are inuested with the *pia mater* or thin *meninx* (and when that is taken off may be better discerned) which not onely compasseth them and contayneth them in their superficies, but also with them in many places diueth into the depth of the braine.

Some

FIG. I.



II.



Some are of opinion that these conuolutions are onely framed of necessity, but haue no vse at all: but we with *Galen* do determine that their vse is to secure the vessels, that going together with the *Pia mater* they might carry vnto the braine nourishment and life, and not be in danger of breaking in the perpetuall motion and agitation of the brain. For the *Pia mater* being a thin and fine membrane and simple (not double that the vesselles might run betwixt the duplication thereof) needed these winding Meanders to secure the vessels. Their vses. *Galen.*

But if the superficies or surface of the braine had bin smooth and æquall & the vessels had run along about the circumference thereof they had been subiect to breaking, especially in the *Dyastole* or Eleuation & in the full of the Moone, at which time the braine by reason of the humidity thereof so swelleth that the vessels must needs haue borne vpon the Scull. Beside, the vesselles would not haue beene sufficient to haue irrigated and watered the huge and vast body & bulk of the brain if they had onely runne ouer the surface thereof. *Platerus* addeth further; because the venall and arteriall bloud arising to the braine is not yet fit for the vse thereof, it was necessary it should runne in proper vessels, and that into the inmost substance of his marrow where the inbred power of the braine might labour it and purge it from those excrements which are gathered and heaped vp in these Conuolutions, that being so prepared the braine might apply it vnto his nourishment and also for the procreation of Animall spirits. *Platerus.*

Another vse of the Conuolutions remembred also beside *Bauhine* by *Archangelus* and *Laurentius* is; for the recreation of the spirits and the bloud contained in those vessels. For if there had not beene these gyrations in the substance of the braine, the vessels especially in the full of the Moone would haue beene so closely compassed by the Scull, that their motion would haue beene intercepted, and the spirit being compressed would haue beene suffocated or strangled, and the heate for want of ventilation extinguished. Another vse out of *Bauhine Archangelus. Laurentius.*

Erasistratus thought that the braine of a man had more Conuolutions then the braines of other creatures because of his reasonable soule; which conceite of his *Bauhine*, *Archangelus* and *Laurentius* do sweetly smile at, when they behold the same conuolutions in the braine of an Asse, the most dull and stupid of all other creatures. Beside we learne out of *Galen* in his 8. booke of the *Vse of parts* and the 13, chapter, that vnderstanding followeth not the variety of the composition but the good temper and disposition of that bodye which vnderstandeth. *Laurentius* and *Columbus* thinke that Nature by these conuolutions prouided for the lightnesse of the braine, and to make it more prompt and ready for motion. But *Archangelus* taxeth them for it. As if (saith he) Nature could not haue made it of a lighter matter if that had beene behouefull, or a little lesse and so lighter? Beside *Erasistratus* his conceite disputed. *Archangelus* taxeth *Columbus* and *Laurentius.*

Tab.9.Fig.3. ſheweth the braine vncouered from both his Membranes, and laid on the one ſide that the proceſſe or duplication commonly compared to a Mowers Sythe, which diuideth the Braine; as alſo the Callous body might better be ſhewed.

Fig.4. ſheweth the Braine freed from his Membranes, as alſo a part of the braines it ſelfe is taken away that the marrow and the ventricles might be better diſcerned.

TABVLA. IX.

FIG. III.

FIG. IV.

A A, The right ſide of the Braine.
B B, the left ſide of the Braine.
C C, the conuolutions or breaches of the Braine.
D D, the duplication or proceſſe of the *dura meninx* called the Sythe.
E E E, the beginning of the veſſels proceeding out of the third *Sinus* into the thin membrane are heere broken off.
F, A paſſage running out of the fourth *Sinus* in manner of a veine into the lower part of the thicke membrane,
G G, Certaine propogations of this paſſage running vpward into the ſame membrane.
H H, Certaine Surcles diſſeminated from the lower ſide of the third *Sinus* into the proceſſe.
I I, the beginnings of the veſſels which paſſe from the fourth *Sinus* into the thin Membrane.
K the beginning of a veſſell bred out of the fourth *Sinus*, which runneth vnder the arch into the third ventricle to make the *Plexus* or thrumbe of criſped veſſels therein.
L L, the Callous body of the braine.
M M, the *Sinus* on eyther hand, at the ſides of the Callous body.
N, A portion of the Sythe which groweth to the partition of the Organe of ſmelling.
O O, the thin membrane or *Pia mater*.
P P, Parts of the thicke membrane reflected.

Fig.4.

A A A, B B B. the right and the left ſides of the marrow of the braine remaining yet in the Scull,
C C C, A part of the braine taken away,
D D, D, Diuiſions or lines frō the breaches of the braine.
E E E E, the Shel or Barke of the braine compaſsing his marrow.
G G, H H, the marrow of the braine which when it is preſſed is full of red points or ſmall drops or graynes.
I I I, the Callous body freed on eyther ſide from the ſubſtance of the braine.
K K, A part of the Callous body. L L, M M, the right & the left ventricle of the braine.
N N, A part of the vpper ſide of the left ventricle.
O O, the complication or thrumbe of veſſels called *Plexus Choroides*.
P P, Small veines growing to the ventricles.
Q, Other veſſels running frō the ſame veins into the *Pia mater* or thin membrane.

we ſee that the heart is of a moſt ſolid and firme ſubſtance without any of theſe gyrations & yet it moueth in *Syſtole* and *Dyaſtole* very freely. *Veſalius* and *Laurentius* adde that they were alſo ordained for the ſupportation of the ſoft ſubſtance of the braine that it might æqually be ſupported and not ſway too much to eyther ſide. And thus much for the vſes of theſe conuolutions as alſo for the vpper part of the ſubſtance of the braine.

Another vſe out of *Veſalius* & *Laurentius*.

Now the internall or inward ſuperficies hath in it diuers parts and impreſsions becauſe of the many vſes for which Nature hath ordained it. The ſubſtance therefore of the Braine is by *Archangelus* diuided into the Braine and the Marrow. The Braine he calleth that Aſh-coloured part which compaſſeth the reſt, whereby he meaneth the marrow: we will ſay it may be diuided into the Shell and the Kernell. The Shell is that Aſh-coloured bodye

The inward part of the Braine.

The Shel & the Kernell.

[Tab.

[Table 9. figure 4. Table 10. fig. 5.^{FF}] which compasseth immediatly the kernel or marrow. The kernell or marrow is that white body [Table 9. fig. 4. ^{GH} Table 10. fig. 5. ^{GH} Table 11. fig. 7. and 8.^{BB}] which is hid within the ash-couloured body and is somewhat more solide; for this white body is within the ash-coloured body as the christaline humor of the eie is in the glassie humour. Wherefore the shell differeth from the kernell first in colour, the one ash-coloured the other white; then in consistence for the shell is softer the kernell a little harder firmer and more compact; then in scituation because the kernell is in the middest the shell in the circumference distinguished with oblique and crooked lines.

Wherefore the kernel or Marrow is the middle and white body of the braine, of which there are two parts; one contayned within the skull, the other falling out of it and lengthned downe to the great hole of the *occiput* and ending in the spine of the back. These two bodies also, the shel and the kernel, may actually be separated if we haue the head of a sound man newe slaine and presently with dexterity dissected, otherwise both of them will grow very moyst and extreame soft, as it hapneth to the mammillary processes which are the instruments of smelling, which in a fresh body may easily bee parted at the marrow, but not so if the body haue beene dead any time. The kernel or marrow. Note this.

Now if you dissect the braine ouerthwart, about the middest of it you shall perceiue small vessels therein descending to his ventricles, and if the marrowey substance be pressed there will start out of it many drops or graines of bloud, which make me remember that of *Hip.* in his book of the falling sickneſse. *Many and small veines doe ascend out of the whole body vnto the braine, and especially two notable, one from the Liuer another from the Spleene*: in the quest of which (if any such be) I would haue the great Anatomistes spend some of their curious howres. A difficult place in *Hip.*

Aristotle in the first booke of his History and the 16. Chapter is of opinion, that the braine is altogether without bloud (that we finde false by manifest experience) neither contayneth any veine within it, but that onely the Meninx about it hath veines. *Vesalius* leaneth too neare vnto him, for these are his wordes: The substance of the Braine and Afterbraine is neuer found with any veines therein, although you shall find in those that die mad or phreneticall and such as are hanged, certaine red and bloudy specks or spots; but these spottes carry no resemblance of a veine at all. Notwithstanding, though these two great Clarkes, the one the Genius of Nature and the very President of her priuy Councell and the other the Eye of Anatomie, haue thus resolued vpon the case: I presume there is something in that *Hippocrates* hath so particularly related, whose vse is not so peremptorily to seduce his Reader: but I leaue the disquisition to those whose meanes and oportunities are fit for such priuy searches, onely adding this one thing which I confidently auouch, that the onely writings of *Hippocrates* after so many ages and Commentaries past, haue in these dayes led the diligent and studious Readers into the knowledge of more mysteries of our Art, then all the writers in the world beside; for he alone is a boundlesse and bottomles ocean of Physicke: we returne to our history. *Aristotle.* *Vesalius.* Commendation of *Hip.*

If you lightly with your fingers deuide the sides of the braine till you come to a veine of a notable bignesse running through his length and sprinckling branches on either hand into the braine, there will offer it selfe vnto your view a body placed exactly in the middest of the braine [Table 9. fig. 3.^{LM}] gibbous or rising somewhat round [Table 9. figure 2.^{L}] in which sayeth *Archangelus* the two first ventricles are excauated, long, narrow, smooth and equall, whiter also then the vpper part as being made of the marrow or inward substance, which because it is harder and somewhat like a callus or hardneſse of the skinne gotten by labour but much whiter is called τυλώδες σῶμα, by *Galen* in the 9. Booke of his Anatomicall Administrations and the third Chapter, that is, *A callous body*. It is a part continued with the braine, wherefore at the sides thereof in his length two *Sinus* or ventricles [Table 9. fig. 3. at^{N}] are hollowed in the marrow of the braine like deep lines or hollow pipes, which are esteemed to receiue the defluxion, of rheume, or phlegme out of the vpper partes of the braine, and to send it forward by the gibbous *superficies* of the callous body vnto the nose. But the vse of the callous body vndoubtedly is by his vpper part to sustaine the waight of the braine which lieth vpon it, and that by his mediation both the parts of the brain might be conioyned, as also to make a distinction or hedge which they call *septum* [Table 10. fig. 1.^{XX} holdeth vp ^{YY}, ^{XX}, and ^{XY} lift vp ^{SYT}, least ^{AAA} in the sixt figure should presse ^{HI} in the same fig, or ^{E} in the 7 and 8. figures of the 11. Table] which separateth the two ventricles; which partition it also sustaineth & lifteth vp the arch called *Fornix*, least falling downe it should The *Corpus Callosum.* *Archangelus.* The vse of it.

compresse the third ventricle.

A story out of *Bauhine*. In this place sayth *Bauhine* in the yeare 1582. I found a scirrhus or hard tumor in the noble Baron *Bonacurtius* (who lay a long time in a manner Apoplecticall or astonished) when we opened his head after his death.

When we haue cut away the substance of the braine on either hand as deepe as vnto the Callous body before we lift it vp, we must mark the *septũ* or partition of the two first ventricles.

The *septum lucidum*. This *septum* or partition [table 10. fig. 5. at ʀʀʀ reflected backeward] in the vpper part groweth to the Callous body and is perfectly vnited thereto (wherefore *Vesalius* calleth it the inner or lower *superficies* of that callous body) but below it groweth to the place of the Arch or *Fornix*, so that it standeth in the middest between the callous body and the Arch. This *septum* before it be stretched is loose & rugous and doeth not shine, neither can you perceiue how it is continued with those bodies of the *Callus* and the Arch; but drawe it vp so high till it be streatched (and take heed it breake not for it is but thinne) and then if you Diuersly compared. put a waxe candle to one side of it you shall perceiue the brightnesse of the light through it as if it were through a glasse. *Vesalius* compares it to the host in the Masse, which being a thinne wafer and a little wet you may see a dull light through it; or say it is like a sliuer of the Muscouy glasse whereof we vse to make Lanthorns, or the horne of a lanthorn it selfe.

The names of it. Whereupon *Columbus*, *Archangelus* and *Laurentius* haue called it *speculum*, *speculum lucidum*, *septum lucidum* and *lapis specularis*, the Looking-glasse. *Galen* giueth it a name from his vse in his 9. Book *Anatomicis Aministrationibus*, the first, the third and the fourth chapters, calling it διάφραγμα τῶν προσθίων κοιλιῶν, *The partition of the foremost ventricles*, because the inner lips of the ventricles are hereby distinguished; wherefore you cannot aright perceiue it vnlesse both the ventricles be layd open, and if it be neuer so little too much streched it easily breaketh, because it is so very thinne and subtile, yet cannot it not be manifestly seene vnlesse it be lifted vp.

An Anatomist therefore in these curious thinges had neede to haue a fine and a dainty hand and at command. This partition is of the same substance (sayth *Galen* in the book before named and the third Chapter and after him *Vesalius*) with the braine but thinner, and in respect of his tenuity as it were the substance of the braine drawne out into a membrane. *Columbus* and *Archangelus* thinke it is nothing else then the *pia mater* in this place duplicated; but *Laurentius* and *Bauhine* agree with *Galen*. Yet though it bee thinne it is not simple, and it hath in the middest a little rising like a line [Table 10. figure 5. ʏ] which line bearing downward is by degrees lessened and becommeth the partition of the ventricles [tab. 10, fig. 5. the lower part of the *septum* at x x the vpper at ʏ.]

The substãce of it. *Galen* & *Vesalius*. *Columbus* & *Archangelus*.

These ventricles beeing taken away to the middest of their substance, wee meete with foure swelling particles: two before, about which is the Basis of the ventricles; two on the backeside making the Arch or *Fornix* of which wee will entreate in the next Chapter.

CHAP. XI. *Of the ventricles of the Braine, the Arch, and the Plexus Choroides.*

The ventricles of the braine. ALthough the Cauity which is in the Brain be continuated quite through, yet because according to the forme of the Braine and the vse it is diuerslie formed, so that one part is more dilated another more angustated or contracted; therefore the Anatomists haue diuided it into certaine places, and the larger of them they cal ventricles, the narrower they call *meatus* or passages. The ventricles called by *Galen* κοιλίας, the Antients and many of the new writers also following therein *Herophylus* haue reckoned foure. In the Braine three; two foreward a right and a left, and the third in the middest. The fourth they make common to the after-braine and the spinall marrow.

The first two of (these called by *Archangelus* the *Superior* because they hang ouer the other; by *Galen* in his 8. booke of the *Vse of parts* the 10, 11, and 12, chapters and diuers other places the *Anterior* ventricles) are cut out of the marrow of the braine and are the largest of all the rest, because (saith *Laurentius*) they containe a crasse spirit or rather aboundance of phelgme. They are on eyther side one, the right on the right hand and the left on the left, alike each to other in scituation, forme, magnitude and vse. They are scituate lengthwise in the marrow of the braine in the very middest thereof, [Tab. 5, fig. 4, Tab. 10, fig. 5, fig.

fig. 6, the right is noted with [r] but the left in the 9 Table and the 4, figure and the 10. Table and the fift figure at [M] in the 6. figure at [E]] whether you respect the length or the depth of it. In their fore and hinder parts they are broader and more disioyned, in the midst lesse where they are only diuided by that thin partition we spake of in the former chapter. [tab. 10, fig. 5, [xxyy]] They runne obliquely or semicircularly saith *Archangelus*, [Tab. 9, fig. 4, from [L] to [M]] for beginning about the temples where the marrow begins, they are by little and little curued toward the center of the marrow, and at the Region of the Eares they are bent againe, and so seeme to make two Semicircles. They are long, winding & somewhat large. Their forepart is blunt and round [tab. 9, fig. 4, and tab. 10, fig. 5, [L] and the lower [M]] and in their inside they sinke downe vnto the third ventricle, [Tab. 10, fig. 5, vnder [S T V] and in the 6. figure at ["] and [I], in the eleuenth table and the 7, fig. at [R]] whereupon some who haue not diligently followed their curued passage haue thought that beside these two there are other two ventricles in the forepart of the braine, and so haue made vp the number of sixe ventricles: but we esteeme them to be portions of these vpper, for they are indeede larger then vsually they are esteemed. Backward also they are obtuse and round, [tab. 9, fig. 4, the vpper [L] and [M]] and do descend by degrees downeward into the substance of the brayne, and foreward are straightened like the small end of a horne, and so creepe on to the mammillary processes and the ingresse of the opticke Nerues [tab. 11, fig. 7, and 8. [F O]] and the sleepy arteries. Their vpper face is lined with a waterish moysture, and they are often found full thereof. Their vpper part [tab. 9, fig. 4, from [L] to [L] and from [N] to [N]] according to the length of the braine is smooth and æquall; the lower part is vnæquall. [tab. 10, fig. 6, [R] or [S]] because of the hollownesse prepared to receiue the defluxion of the phelgme; which hollownes creepeth obliquely out of the backepart of the ventricles foreward into their common cauity: For these two ventricles, as we shall say by and by, do determine into a common cauity. *Galen* and the ancients after him do write that the superficies of the first three ventricles are as the brayne couered with the *Pia mater*. *Vesalius* denyeth it and addeth a reason: for, saith he, if the ventricles were lined within, the Membranes would hinder the substance of the braine from working the matter conueyed into them into Animall spirits. But *Columbus* and *Archangelus* side with *Galen* against him, and *Archangelus* thinketh that the *septum lucidum* is made of the duplication of the *Pia mater* after it hath inuested these ventricles. We leaue this to be farther scanned by the curious Dissectors: sure we are that that which is called *Plexus Choroides* lyeth vpon them, from whence small veines [tab. 9, fig. 4, [P P]. tab. 10, fig. 5, [r] figure 6, [o o]] are deriued which grow in the forepart to their substance, like vnto those which runne through the coate of the eye called *Tunica Adnata*. *Archangelus* is of opinion that the *Pia mater* being it selfe of exquisite sense may by meanes of these small veynes suffer inflamation, whence come those deepe paines which are sometimes felt in the Center of the brayne. And indeed *Galen* maketh expresse mention both of the *Pia mater* compassing their cauity as we haue saide before, as also of these veines which insinuate themselues into the ventricles in the second and third Chapters of the 9. Book of his Anatomicall Administrations: so that *Archangelus* doeth but gather the conclusions out of *Galens* præmises.

Their figure.

The water in them.

Whether they bee lined with the *Pia mater*.

Vesalius against *Galen*.

The cause of deepe paines in the head.

It behooued sayeth *Galen* in the 8. Booke of the *Vse of Parts* and the 10. Chapter, that there should bee two of these ventricles, (because the Braine and euery organ of sence is double; for the braine is the first and most common cause of all those double organs) that if one of them be violated, the other might serue the turne; and this hee prooueth by an instance of a young man of *Smyrna*, who was wounded into one of these ventricles and yet escaped: but sayth hee, if both of them had beene wounded he could not haue liued a moment of time.

Why two ventricles out of *Galen*.

A story by him cited.

Vesalius (as he is an importunate aduersary of *Galens*, the lesse his thanke) reproueth him for this, alledging that though the braine be parted into two, yet it is againe vnited before the ventricles are formed therein; and to say trueth it is hard to conceiue how one ventricle should be wounded and the other not violated, considering the thinnesse of the membrane or partition that parteth them, and beside the common cauity whereinto they both determine; but experience often assureth vs of that which meere Reason and discourse wil not allow of or subscribe vnto.

Vesalius oppugneth him not without some reason.

The vse of these ventricles is according to *Galen* in his eight Booke of the *Vse of Parts* Chap. 10. and 11. that of the ayre which we draw in conuayed into the brain by the organs of smelling & of the vitall spirit ascending from the hart by the sleepy arteries, the Animal

The vses of these ventricles. *Galen.*

Archangelus. Laurentius. spirites prepared before in *plexu choroide* might in those ventricles bee perfected, but how perfected? *Vesalius* thinketh by the particular substance and forme of the Brain. *Archangelus* thinketh they haue no such vse or power as to make Animall spirites. *Laurentius* sayth that they serue for the inspiration and expiration of the Braine, to receiue smels and to prepare the Animall spirites, and to containe them as it were in a store-house yet not perfectly accomplished but inchoated onely. *Archangelus* subscribeth vnto this and addeth moreouer, that the ayre drawne through the nose and spongy bone into the ventricles, is laboured and prepared for the nourishment and refection of the Animall spirites, as the ayre is prepared in the Lungs for the refrigeration & recreation of the vital spirits. Another vse sayth he of them is (but that onely a secundary vse) to serue for wayes whereby the excrements of the braine may be purged. Neither sayth he, is there cause why we should wonder that the same ventricles should hold the Animal spirits and serue also for the ablegation of excrements, seeing we know that Nature hath ordained the Nose first and primarily to be a meanes of smelling, and secondarily to call out the phlegme out of the brain and auoide the same.

Archangelus his other vses

Baubine. Wee sayeth *Baubine* thinke, they serue to gather the excrements which are separated in the nourishment of the Brain, the phlegme (for example there) engendred, and by their common passage to send it into the Tunnell called *Infundibulum* to bee conuayed away by the throate.

A passage to be obserued. *Archangelus* in this place maketh mention of a passage which is (sayth he) is in the middest vnder the mamillary processes and hath a double issue, one directly into the ventricles wee speake off, the other into the pallate and so into the Lungs. This passage is knowne but to a few, neither can it be found but in a sound Brain when the man commeth to a sudden and vnlooked for end and is presently dissected; for the partes of the braine that are about this passage do in a short time so fall and close together that the passage is cleane obliterated.

Galen explayned. Hence *Galen* in his 8. booke of the *Vse of parts* and the 10. Chapter sayed, that the ayre we breath in by our noses passeth vnto the heart, but a part of it getteth into the ventricles where it is prepared and made the nourishment of the Animall spirites. *Columbus* ascribeth the finding out of this passage to himselfe, but *Archangelus* taxeth him therfore. And so much of the two first ventricles.

The 3. ventricle. The third ventricle followeth, which is nothing else but the concurrence or meeting of the two former lengthned out somewhat backward. For the two former ventricles in their lower part vnder the Arch [Table 10. fig. 5. ττ] figure 6. ΔΔΔ] do meet together in one place & there determine, being in their nether parts like a narrow path which runneth out backe ward a pretty length into the hindmost ventricle. This is called by *Galen* in his 8. booke of the *Vse of parts* and the 12. Chapter, the common cauity or common place of the forward ventricles; [Table 10. figure 6. vnder " ' table 11. fig. 7. and 8. "] by others who doe deny the third ventricle it is called the perforation of the two former ventricles: others call it the third ventricle or the middle ventricle, becausе it is in the middest of the braine, yea and in the very Center of the marrowe betwixt the two forewarde ventricles and the fourth.

Galen.

The forme of it after *Galen.* This at the first sight is like a long slit or cauity, [Tab. 11. fig. 7. and 8. "] but more backward it becommeth larger, and is discerned, part of it when the arch is drawne a little backward, part of it when th Testicles and the Buttocks of the braine are diuided in the midst. It tendeth directly from the forward ventricles vnder the arch, the testicles and the buttocks, [Table 12. fig. 10. from ' to "] toward the fourth ventricle [Tab 12-fig 10. " sheweth the end of it]. And this is *Galens* delineation of his passage in his 8. book of the *Vse of parts* and the 11. chapter, whereunto *Vesalius*, *Platerus*, *Archangelus* and *Laurentius* do subscribe, but *Columbus* maketh it shorter and sayth it endeth at the backeward passage neare to the *Glandula pinealis*. The figure of it sayeth *Archangelus* is vncertaine becausе there are many eminencies or inequalities in it.

The two passages thereof. This third ventricle hath two passages, of both which *Galen* maketh mention in his 9. booke of Anatomicall Administrations and the fourth Chapter, the one he calleth the vpper hole or the Tunnell, the other the great hole of the third ventricle, wee according to *Baubine* will describe them thus.

The first. The one [Table 11. fig. 7. and 8. '] proceedeth out of the middest of the ventricle and is reasonable large: it is caued in the substance of the braine and runneth directly downward to-

toward the *Bason* which receiueth the phlegme at the Basis of the braine, and by it the phlegme of the two forward ventricles doth descend.

The other passage [Table 11.fig 7. and 8.[x]] which is the more backeward (*Laurentius* addeth the larger also) is not round in his originall although it be a part of the third ventricle which is round. *Galen* in the 9. booke of his Anatomicall Administrations and the 5. Chapter, thinketh that it hath a peculiar coate like that of the *pia mater* wherewith it is lyned. It runneth vnder the Buttocks [Table 11,fig.7.[MN] fig.8.[NOPQ] table 12.fig.19.[PQRS]] and the Testicles into the fourth ventricle aboue the beginning of the spinall marrow. Out of the lower and forward angle of this passage, as soon as it is gotten vnder the testicles, there issueth another passage [Table 11.fig,8. neare to [x]] farre narrower then the former, which passing slily forward through the substance of the braine, sinketh downeward and determineth in the end [Table 11.fig.8.[y]] of the first passage; out of both which ariseth an orifice [Table 15 figure 20.[n]] which endeth in the *Bason*, and leadeth the phlegme out of the third ventricle. This *Vesalius* taxeth *Galen* for pretermitting, in the place next aboue named. Now whereas at the second passage there appeareth a certaine slitte or cleft, *Columbus* will needs liken the same vnto the lap or priuity of a woman.

Second.

Another passage.

Vesalius taxeth *Galen*.

The vse of the third ventricle is to be a receptacle of the Animall spirit, which also is by Nature so quaintly formed (for *Archangelus* referreth all those resemblances of the arch, the buttocks, the testicles, the fundament, the womans lap and the yarde vnto the third ventricle) that it driueth them into the fourth ventricle.

The vse of the 3. ventricle.

Aboue this third ventricle lyeth the *Fornix* or Arch called καμάρωσις ἡμιολιακή, because in forme and vse it resembleth a crosse vault or arch. *Columbus* calleth it *Corpus camerarum* The vaulted body, which (saith he) is supported with 3. pillers. This arch is but one and lyeth vnder the Callous body almost in the middle of the braine but a little backward, and swelleth equally out of both sides thereof: for it is common to both sides of the brain. It groweth out of the backe part of the two vpper ventricles [Table 9. figu. 4. the vpper [LM] Table 10.fig.5.[ST] figure 6.[xc]] where they bow forward. VVhilest it is contayned within the brain it is a long and callous body, yet broader toward the backpart, but as it creepeth forward it groweth sharpe to his very end. [Table 10.fig.5. from [s] to [y] fig.6. from [xc] to the vpper [A].] At that forward sharpe end [tab.10.fig.6. at [r]] it is againe ioyned to the substance of the braine as also to the callous body; but in the middest and in the rest of his bredth it is free and at liberty [tab.10.fig.6.[xx].]

The *Fornix* or arch.

His names.

And delineation.

The figure of it is Triangular but consisting of vnequall sides, so sayth *Galen* in his eight booke of the *Vse of parts* and the 11. Chapter. *Vesalius* and *Laurentius* call it *semicircular*, or rather like a bridge whose backpart standeth vpon two knees, the forward vpon one. For first in the backpart it reacheth from one of the ventricles ouer to the other, and that side is short [Table 10.fig5. from [s] to [t] and fig.6. from [B] to [D].] The two other sides are equall and somewhat longer, reaching from the backpart to the forepart [tab.10.fig. 5. from [s] to [v] and frō [t] to [v] fig.6. from [B] to the vpper [A] and from [c] to the vpper [A]] so that backward it hath two Arches and forward one, and standeth like a threefooted stoole vpon the braine.

His figure. *Galen*.

The substance of it is like the substance of the ventricles but somewhat whiter and harder, like the substance of the callous body. It is no where compassed with the *pia mater*, and in the bottome where it archeth ouer the ventricle, it is free and at liberty not tyed to any of the adiacent parts. [Table 10.fig.6.[AAA].] In the sides where it respecteth the two forward ventricles [tab.10.fig.5.at [LM].] it is supported, backeward with two props and forward with one; the superficies of it is smooth and moystned with a watersh humor.

Substance.

On the outside neare the originall it is gibbous, embowed [tab.10.fig.5.[ST]] or conuex, and in the originall *orbicular* or round, that without payne (sayth *Galen* in the 8. *de vsu partium* and the 11.) or desease it might sustain the waight of the braine lying vpon it, that the common passage or third ventricle vpon which it coucheth, might be kept open and large and not compressed, because vnder it the two first ventricles do meete.

In the length of it it swelleth a little in the middest like a broade line [table 10.figure 5. [n]] by which it is continued with the partition of the ventricles called *septum lucidum*.

VVithin it is hollow [Table 10.fig.6.[AA]] as well for the free passage of the spirits, as also that the vessell [table 10.fig.6.[n] table 11.fig.7.[y] arising from [r]] arising out of the fourth *Sinus* of the *Dura mater* and deuided into the two forward ventricles, might passe vnder it and not be pressed by the substance of the braine hanging ouer it. And thus much of the arch.

The

Table 10. Figure 5. sheweth the same that the former Table did, saving that the Callous body is the foreside separated from the Braine and reflected backward, and some from the partition which distinguisheth the ventricles; is heere more manifestly to bee perceived together with the Fornix or Arch of the Braine.

Figure 6. sheweth the Arch loosned on the foreside and drawne backward, that the lower part and the vessels might thereon be seene.

TABVLA X.

FIG. V.

Figure 5.

IRR, The lower *superficies* of the callous body reflected.

STV, The *triangular* surface of the Fornix or Arch.

XX, The lower part of the partition of the ventricles continuated with the Arch.

YY, The vpper part of the partition continued with the callous body.

Figure 6.

AAA, The lower surface of the Arch.

BC, Two corners of the Arch by which it is continuated with the ventricles.

DE, The right and left ventricles.

FG, Arteries climbing vp from the sleepy arteries thorough the lower side of the ventricles for the forming of the complication of vessells which is called *Plexus choroides.*

H, A vessel issuing out of the 4. *Sinus* vnder the Arch & passing into the third ventricle.

IKL, The diuision of this vessell, a part whereof goeth to the right ventricle at *K* and another to the left at *L.*

MN, The *Plexus choroides* made of the artery FG and the vessell H.

OO, Small veines passing thorough the ventricles of the braine produced from the vessels K and L.

P, Other veines arising from the same, dispersed without the ventricles into the *pia mater.*

Q a passage from the third ventricle vnto the *Bason or Tunnell.*

RS, Canales or *Sinus* grauen or furrowed in the substance of the ventricles in which the phlegme is led along to the orifice of the foresaid passage marked with Q.

The *Plexus Choroides.* The names.

The *Plexus Choroides* hath his scituation in the forward ventricles [Table 13. figure 13. δ] betwixt them and the Arch, they are called χοροειδὴ πλέγματα, because they are like the χόριον that is, the After-birth or membrane which compasseth the Infant. But by all Anatomists they are called *Plexus Chore formes* or *Reticulares.*

what it is.

They are complications of small vessels in the ventricles of the brain compassed with the *pia mater* [Table 9, fig. 4.^o table 10, fig. 5.^o fig. 6.^MN.]

Diuers descriptions thereof.

How and of what vessels they are made is diuersly set downe by the Authours of Anatomy, and because it is a speciall matter and of subtile conuayance, I will not spare my labour to set downe the diuers delineations of *Archangelus, Laurentius, Vesalius, Fallopius,* and *Bauhine.*

Ar-

Table II. *Figure* 7. *sheweth the Brain, wherein that part is taken away which made the vpper ventricles and did lie vppon the* Cerebellum: *here also the vessell led along from the fourth Sinus, is separated from the* Plexus Choroides *& soeleuated, that the third ventricle, the Sinus of the* Dura Meninx, *and the After-braine it selfe may better be deseerned.*

Figure 8. *sheweth the Braine yet further dissected and more of it taken away, so that the Testicles are diuided that you may see the passage of the third ventricle into the fourth, and the* Cerebellum *vncouered from the thick membrane.*

TABVLA. XI.

xx, vessels from the *Dura meninx* sprinkled in-
zz, the cōnexiō of the *dura meninx* to the skul.

Archangelus thus: It is made of arteries (to which no veines are ioyned) creeping vp into the ventricles through the inside of the braine from that admirable net or complication seated in the *saddle* of the wedge bone. *Archangelus.*

Laurentius thus: It is a mazey laberynth of small veines and arteries running through the parts of the *pia mater* as it riseth vpward. *Laurentius.*

Vesalius and with him *Platerus* thus: It is wouen of a braunch of the fourth artery, and of *Vesalius & Platerus.*

of the veſſels proceeding out of the fourth *Sinus* of the *dura Mater*, and of the *Pia Matter*, and a duskiſh kinde of fleſh.

Falloppius. *Falloppius* in his Inſtitutions more particularly thus. It is made of Arteries onely without any admixtion of Veines, partly of the Soporary Artery which alſo maketh the *rete mirabile* or wonderful Net, partly of Arteries which aſcend through the tranſuerſe proceſſes of the Necke and go into the Braine by that large hole whereout the ſpinall marrow yſſueth; and are led vnder the Baſis of the braine, and do degenerate into Veſſelles like Veines, which vniting themſelues into one braunch doe approach forward to that place where the wonderfull Net is made by thoſe ſoporarie Arteries, and being vnited with theſe do make the *Plexus Choroides* which paſſeth through all the foure Ventricles, & as it paſſeth thorough the third Ventricle when it commeth to the fourth *Sinus* of the *Dura Mater* it is ioyned thereto by certaine ſmall and ſlender branches.

Bauhine. *Bauhine* yet more particularly thus. It is wouen of veſſels which arriue at the Ventricles partly running from the fourth *Sinus* of the *Dura Mater*, partly of Arteries ariſing other-whence. For from the end of the fourth *ſinus* of the *Dura Mater* [Tab.13,Fig. 13,^{i}] is formed a venall Veſſell, [Tab.13,Fig.13,^{i}] which running through the middle ventricle is led along in the forward Ventricles. [Ta.13,Fig.13,^{lm}] So alſo another of a branch of the fourth *ſinus* which goeth downeward and forward to the vpper Ventricles [Tab. 13,Fig. 13,^{s}] And another of a branch of the fourth Artery of the Braine which paſſeth into the Ventricles. [Tab.13,Fig. 13,$^{\wedge}$] All theſe Veſſels are accompanied with a portion of the *Pia Mater* which embraceth them and knitteth them together; a reddiſh Fleſh or Glandulous ſubſtance being ſcattered betweene them: which Veſſels, Membrane and Fleſh make the *Plexus Choroides*. This Webbe or complication ariſeth from the Lower part of the Ventricle to the backe part of the Ventricles, and ſo paſſeth on till it meete with that Venall veſſell [Tab.13,Fig.13, from ^{i} to ^{x}] brought from the fourth *ſinus* forward thorough the third Ventricle where they ioyne together, and then it diſtributeth ſmall branches through the ſubſtance of the Ventricles [Tab.10,Fig.6. from ^{z} to $^{\phi}$ to ^{xx} after to ^{xl}, then from ^{i} to H. Tab.13,fig.13, from $^{\wedge}$ to $^{f\,l\,r}$]

The vſe of the *Plexus Choroides.* In theſe complications are the Animall ſpirits concocted, attenuated and prepared, *Columbus* (as he is alwaies his owne friend) brags that hee firſt found out the generation of the Animal ſpirits in this web: but *Archangelus* gaynſayeth him and quoteth *Galen* where he maketh mention of the ſame. He alſo thinketh that the Animall ſpirit is but inchoated in the *Rete mirabile* and perfected and abſolued in this complication: but the power whereby it is perfected is from the ſubſtance of the Marrow of the Braine it ſelfe. And then that they are powred out from this *Plexus* into the forward Ventricles, and thence into the Organes of the ſenſes. *Platerus* cannot admit of this vſe of the Plexus, but ſaith, that becauſe the inner ſubſtance of the Braine hath no ſuch complications or gyrations as the outward hath, or veſſels deriued vnto it; theſe Veſſelles were by Nature ordained in the center therof, that by them it might receiue vital ſpirit and a proportion of blood, that as the outſides had aboundance, ſo the inſide might not bee altogether deſtitute of life and nouriſhment. And thus farre of the *Plexus Choroides*.

Platerus his conceit of the vſe of it.

CHAP. XII. *Of the Glandule called* Pinealis, *the Buttockes, the Teſticles and the fourth Ventricle of the Braine.*

The Pine. glandule. IN the third Ventricle at the entrance into the fourth, [Tab.11,figure 7^{r}] there is ſeated a Glandule or Kernell, [Tab.11,Fig.7,^{l}.fig.8,^{M}. Table 12 fig.10,H] reſting vpon the foreſide of the Teſticles, [Table. 11,fig.7,$^{M\,N}$] Tab. 12,fig.10,$^{\pi\,\rho}$] and lyeth vnder the Venall veſſel [Tab.10,fig.6,H,I. Tab.11,Sig.7,^{v}. Tab.12,fig: 10,$^{\tau}$] which ſpringeth out of the fourth *Sinus*, with which veſſell alſo in Diſſection it is eaſily drawne away from the Braine, for in men it ſcarſe cleaueth to the ſubſtance of the Braine, but in a Sheep or Calfe it is continuall after a manner with the ſubſtance of the Braine: alſo in Beaſts it is much larger then in men, yea not onely this Glandule but all the other partes and particles of the Braine are farre larger and more conſpicuous in bruite beaſts then they are in men: and therefore it is fit that yong men ſhould bee initiated and exerciſed in cutting vp the braines of a Calfe or ſuch like, that when they come to diſſect a man they may not be too farre to ſeeke.

Calfes heads fit to cut vp.

The Figure of it is like a Cone, that is a round turbinated figure, much like the fruit of

Table 12. *Figure* 9. *Sheweth the* Cerebellum *drawne a little out of the skull aboue the Braine, that the lower surface thereof and the cauity of the spinall Marrow might better bee discerned.*

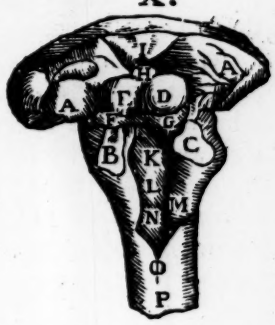
XI.

X.



XII.

AA, a part of the Braine left in the skull.

BCD, Three parts of the *Cerebellum* reflected, incompassed with the *Pia mater* and growing to the marrow of the backe.

E, The hindermost processe like to a worme called *vermi-formis*.

FGH, the beginning of the spinall marrow falling out of the skull to H.

I, the greater part of the 4. ventricle which is excauated or hollowed in the marrow of the backe.

K, Vessells deriued to the *Cerebellum* from those vessels which are emptied into the first and second *Sinus*.

L, other vessels from the *dura meninx*, sprinkled into the *pia mater*.

MN, the fist and sixt coniugation of nerues.

O, the toppe of the fourth ventricle like the neb of a quill.

PQR, The backeward bosome of the skull made to receiue the *Cerebellum*, which bosome is yet couered ouer with the *Dura meninx*.

SS TT, the first and second *Sinus* of the *dura mater*.

Figure 10.

AA, Parts of the spinall marrow cutte from the braine.

BC, the places where this marrow did grow vnto the braine.

DE, the Testicles. FG, the buttocks, H, the pine-glandule.

From I to K, a part of the third ventricle going to the fourth, vnder the Testicles.

KLMN, A part of the fourth ventricle which is engrauen in the marrow.

O, the top of the fourth ventricle.

P, the place where the spinall marrow goeth out of the skull.

Figure 11.

AB. Parts of the optick nerues.

CD, the sleepy arteries. *E*, the *Bason* or Tunnell hanging downe.

F, A hole or perforation of the *Dura meninx*, through which the Tunnell reacheth vnto the glandule.

GG, parts of the second coniugation of sinnewes.

Figure 12.

A, The Glandule. *B*, The *Bason* or Tunnell called *Peluis* or *Infundibulum*.

CDEF, the foure holes thorough which the phlegmatick excrement issueth.

a Pine-apple, broade and round in the Basis, and growne smaller but keeping round to the top; and hereupon it is that it is called κωνάριον, and *Glandula Pinealis*: some haue resembled it to the end of the Virile member, and therfore call it *penis Cerebri*, the yarde of the brain. Somewhat long it is, and the Basis sayth *Vesalius* resteth vpon the substance of the braine, but the top regardeth vpward.

The

Substance. The substance of it is somewhat hard, rather sayeth *Vesalius* inclining vnto the nature of a glandule then of the Braine, and couered with the thinne membrane. The colour of it somewhat differeth from that of the marrow, as being a little yellowish. It lyeth vnder the vessell sayth *Bauhine* [Table 10.fig.6 H] which goeth to the third ventricle, from which vessell all the webs almost which are in the ventricles doe proceede: and hath the same vse that other glandules haue, which are placed vnder vessels, that is, to confirm their diuisions. For as soone as this vessell entreth into the third ventricle, it is presently diuided into many branches couered ouer with the *Pia Mater*; and therefore the glandule becommeth to them a streng h and stay; but *Archangelus* denyeth this vse of it. Againe, it hath another vse acknowledged by *Vesalius*, *Platerus* and *Laurentius*, and that is to keep the passage of the third ventricle open that it bee not stopped by the ingate of the fore named vessell, and so the Animall spirit hindered from descending into the fourth ventricle.

Vse.

Archangelus his conceit. *Archangelus* obseruing that this glandule was placed at the beginning of the middle or third ventricle, out of which the spirit is transmitted into the ventricle of the after braine, thought that this glandule had the same vse that the *Pylorus* of the stomacke hath, to be a Porter as *Galen* saith to moderate the outgate of the spirits. But the the trueth is, that this Glandule can haue no such vse because it is no particle of the Braine, neither adhereth to the inward sides of the ve tricle, but only lyeth vpon it on the outside; neither indeed doth it so nearely touch the passage as that it can stop the same. Indeede if it were a part of the brane (sayeth *Galen*) then it were more likely, that as the braine is dilated and compressed, the Glandule also should alter his position and somtimes open the passage sometimes shut it, but seeing of it selfe it cannot moue being no part of the Braine, this vse cannot bee attributed vnto it.

Disproued.

The Testicles and Buttocks. Vnto the backeside of the Pine-glandule on either hand the third ventricle and vnder the Arch doe leane foure [Table 11.figure 7.^{MN} figure 8.^{NOPQ}, table 12.fig.10.^{EDFG}] small bodies, which *Galen* in his eight Booke of the *Vse of Parts* and the 14. Chapter, calleth thinne and long eminencies of the braine, for they swell vp round and are somewhat hard. They are particles of the Brain and of the same substance therewith, but their colour approcheth nearer sayth *Vesalius* to the colour of the Braine there where it lyeth next to the *Pia Meninx*. In their lower part they grow out of the Braine, but aboue and at the sides they are not continued to any part of it or in it, but are onely couered with the *Pia mater*; but because they are scituate betweene the forepart of the After-braine and backside of the third ventricle they are better descerned when the *Cerebellum* is taken away.

And because they carry the representation of two buttocks ioyned together, *Galen* in his 8. Book of the *Vse of Parts* and the 14. Chapter called them γλουτία that is, small buttocks; and if you marke well the meeting of these two, and also cast your eye vppon the spinall marrow that descendeth by them, you will readily compare them to a mans thighes set close together. Others comparing the to Testicles, had rather call them διδυμία then γλουτία. Others, because these bodies are not separated into parts, but distinguished onely by an ouerthwart line [table 12.figure 10. betwixt ^{ED} and ^{FG}] do call those parts of them which are next to the Pine-Glandule [table 12.figure 10.^{N}] and vppermost, Testicles, and those that are lower, Buttocks: because in their lower and backward part [table 12. figure 10. vnder ^{F} and ^{G}] when the After-braine is remoued, the passage out of the third ventricle into the fourth conspicuously appeareth [tab.11.fig.8.^{K} table 12.fig.10 aboue ^{K}] which passage resembleth the very fundament between the buttocks.

Their vse. The vse of these bodies is to sustaine the waight or bulke of the braine, least the third ventricle or the passage [table 11.figure 7.8.^{K} table 12.figu.10.^{IK}] which goeth out of the third into the fourth should be compressed, and so the Animall spirit intercepted. Some thinke that these particles driue foreward the Pine glandule to shutte vp the passage of the ventricle: and *Archangelus* thus. The Testicles thrust forward the Gladule, and the Buttockes thrust forward the Testicles: for if you deuide these particles and enter a Probe at the backe hole of the third ventricle, you shall more plainly perceiue the other part of the third ventricle scituated vnder the Testicles [Tab.12.figure 10.^{I} and ^{K} shew the whole third ventricle] which endeth into the fourth.

The fourth ventricle. The left ventricle which *Galen* in his 8. Booke of the *Vse of Parts* and the 12. Chapter, calleth the ventricle of the *Cerebellum*: *Laurentius sinus quartus* the Common Anatomists the fourth ventricle [table 12.fig.9.^{I} fig.10.^{IMNO} with table 15.fig.21.H] is scituate betwixt the After braine and the spinall marrow for it is common to them both: so sayth *Vesalius*

It

It is compounded of the hollownesses of the *Cerebellum* and the Marrow of the backe, no otherwise then if you ioyne both your hands together and make one hollownes between them, or as *Fallopius* hath it in his Institutions. It is scituate in the back part of the Braine, betweene it and the *Cerebellum* where the beginning of the spinall Marrowe ariseth out of the braine, for in it it is for the most part formed. It is the least and the finest of all the Ventricles: the figure of it is round, but withall somewhat long after the fashion of an Egge. At the first it beginneth somewhat large and by degrees is straightned till at length it end in a sharpe corner. For the lower and chiefe cauity of this ventricle is in the spinall Marrow [Tab.12,fig.10, from ˣ to °] hauing a hollownesse like a slit, which sinus *Herophylus* likened to the cauity of a writing pen, the end of it which is resembled to the neb of the pen arising on eyther side [Tab.12,fig.10, ᴺ] like a wing. The vpper part of it is made of the After-brain and the *pia Mater* encompassing it. [Tab. 15, fig. 21 H] For this Ventricle is lined with the *pia Mater*, before [Tab.11,fig.7, ᵒᵒ neere to ᴺᴺ] where it ioyneth the *Cerebellum* to the Braine and to his buttockes, behind [Tab.11, fig.8. as it were ioyning ᶻ to ᴺ] where it ioyneth the *Cerebellum* to the spinall Marrow.

The Figure.

Calamus scriptorius.

This Ventricle is not double but single, because out of it the Spinall Marrowe was to be produced as *Galen* saith: now the Spinall Marrow is single, for it had not beene possible, or if possible, it had not beene fit that one Creature should haue hadde a double Spine. The magnitude therof is conuenient to receyue the Animal spirits out of the forward Ventricles by the common passage or third ventricle and to communicate them to the Nerues which vnder the head are distributed into the whole bodie, whence it was that *Herophylus* called this Ventricle *Principalissimum*, the most principall. Yet it is lesse then the forward Ventricles, because (sayth *Galen*) it conteyneth a thing of more power and Faculty. In this ventricle *Vesalius* thought was the seate of the Memorie, but wee knowe and are able to demonstrate that no cauity of the bodye is the seate either of the sensatiue soule or of any of her Faculties, but rather the solid substance of the parts.

The magnitude.

Herophylus.

The vse of it.

Vesalius his conceite disprooued.

This Ventricle we finde in Dissections (as also al the rest) to conteine in it a wateriſh moysture. The two forward beside this water conteyne also the *Plexus Choroides* [Tab.9. fig.4. OO. Ta.10,fig.5,OO.fig. 6, ᴹᴺ] and the third the Venal Vessel [Ta.10, fig. 6, H, I. Tab.11.fig.7, ᵛ brought out of ᵀ] which is propagated from the fourth *sinus* of the *dura Meninx*, and maketh the *plexus* as we saide before more complicated. Many there are who thinke that all these foure Ventricles do conteine the Animal spirits laboured and perfected in the *plexus Choroides*.

What euery one of the ventricles conteine.

CHAP. XIII. *Of the Tunnel, the Flegmaticke* Glandule, *the wonderfull Net, and the vse of the Braine.*

AT the first or forward hole of the third Ventricle, or at the sides of that hole or orifice [Tab.11,fig.7,and 8 I] we meet with a deepe cauity ioyned aboue to the Braine and made (as saith *Galen* in his ninth booke of the Vse of parts and the third chapter) of the *pia mater* compassing the basis of the Braine. For of this *pia mater* lengthned out is made a round processe or production, [Tab. 15. fig.20. ᶜᶜ] whose beginning is large and ample, [Tab. 12, fig.11, ᵗ fig.12, ᵗ] but after is straightned into a pipe till it end in a long Fistule or quill (wouen with small but many veines) which through a proper hole [Tab.12. fig.11, ᵗ] made for it in the *Dura mater* descendeth and determineth into the Pine-Glandule. This passage by *Galen* in his ninth Books of the Vse of parts and of Anatomicall Administrations and the third Chapters, as also by many that haue followed him, is called πυελὸς *peluis* the *Bason*. He calleth it also in the place before named χοάνη *Infundibulum* the Tunnell, because in the top it serueth as a Tunnels top to admit the Humor, and in the bottome like the pipe to let it out; for by this the thicker excrements of the Braine stored vp in the ventricles are receiued and transmitted to the Flegmaticke Glandule of which we shall speake by and by. *Vesalius* maketh the vpper part to be called πυελὸς, and compareth it to a Bathing tub such as they vse in Hot houses. The neather part χοάνη, which cannot be better compared then to the pipe of a Tunnell such as they run Beere with.

The Tunnell.

His Names.

Vesalius.

Concerning the vse all Anatomists do agree; but *Laurentius* me-thinkes for the fashion and the vse compareth it best to such a bagge as wee call *Manica Hippocratis* in English commonly an *Hippocras* bagge, because through it they run; *Hippocras* which is called *Hip.* wine. Next to the bason followeth the flegmatick Glandule. *Galen* in his 9. book *de vsu*

Glandula pituitaria.

partium and the third Chapter calleth it simply δδὸν, that is, a Glandule. The seate of it is vnder and without the Meninges at the end of the Tunnell in the saddle of the wedge-bone. For this saddle or bosome of the bone was purposely made to receiue this Glandule: and therefore the forme of them both differeth little; for it is flat hollow aboue, gibbous below and almost foure square. The substance is Glandulous, but yet more compact and harder then other glandules. Thicke it is and compassed about with the *Pia mater* haply with that part thereof which maketh the Tunnell, and by this Membrane it is tyed to the bone and leaneth to two branches of the *soporary* Arteries called *Carotides* which creepe vp by the sides thereof. [Table 12, fig. 12. C D E F] This Glandule receiueth the excrements in manner of a sponge as they fall from the braine, which extrement it not onely emptieth into the palate, but also some fals downe by his sides through those holes which are bored in the Basis of the Scul. Neyther was *Hippoc.* ignorant hereof, who in his books *de Glandulis* & *de locis* in *omine* saith, that *Humors fal out of the head through the eares, the eies, the nosethers by the Pallat into the throat & the gullet, some also through the veins into the spinal marrow and into the bloud: that is 7. wayes.* For at the sides of this Glandule there are bored two holes in the bōe which descēd, one forward ending in that hole where through the 2. payre of sinewes is led, the other descendeth more backward and passeth by the sharp Cleft at the sides of that hole through which that notable branch of the *soporary* Artery ascendeth into the Scull, of which outlets we shall speake more at large in the History of the bones.

His substance

Vse.

Hippocrates.

And these are the wayes by which the phelgme is euacuated out of the braine. For the braine being great and large stood in need of much aliment, and because it is very moist & not very hot out of that much aliment many excrements do arise & are gathered therein; which excrements being of two kindes thinne and thicke, the thin do vapour out through the Sutures, the thicke are euacuated partly by the Nostrils as we haue saide already, partly by the Palate. For those that arise aboue the Ventricles and are stabled in the diuision of the braine are purged by the foreward hole and the Nose, and is called *Mucus*; we giue it a homely name but proper to it, and call it Snot.

But those that are gathered in the ventricles do most what descend to the Tunnell and are auoided by the Palate, eyther by simple spitting which we call Rheume, or else by excreation or hawking which we cal phelgme. And thus much of the Glandule & vse therof.

Wonderful Net.

Wherof made

The vse of it.

The *Rete mirabile* or wonderfull Net which *Galen* (in the 9. booke of the *Vse of parts* & the third chapter) calleth, δικτυοειδὲς πλέγμα, [Tab. 13, fig. 14,] that is, the Net like complication, hath his name from the artificiall figure; for it is made of the soporary arteries, [tab. 13, fig. 14. A B] which arising vpward from the heart through the Chest climbe vnto the head and at the Basis of the Brayne neere the originall of the opticke Nerues, do make this web or Net. This net compasseth the glandule [Tab. 13, fig. 14, B] at the sides of the saddle of the wedge-bone, and is not like a simple Net, but as if you should lay many fishers Nets one aboue another, wherein this is admirable, that the replications of one are tyed to the replications of another so that you cannot separate the Nets asunder, but they are all of them so wrought into one another as if it were a bodye of Net meshed together not into breadth onely, but euen into thicknesse also. In these according to *Galen*, the Animall spirits make long stay; which haue for this proper and immediate matter the vitall spirits raised vp in the arteries and heere wrought into Animall, from whence they are conueyed into the ventricles of the braine. For saith *Galen* (in his 9. booke of the *Vse of parts* and the fourth chapter) where Nature intendeth exactly to forme any thing she prouideth that it shall remaine some good space in the instruments of concoction. Some are of opinion that the vitall spirits are prepared in these small arteries, and some (*Archangelus* for instance) that the Animall spirits are inchoated heere and perfected in the *Plexus Choroides*, that hauing receiued their power and efficacy from the Braine & the marrow thereof, they might yssue into the ventricles and there be stored vp for vse.

Bauhine.
Vesalius.

Vesalius affirmeth that this wonderfull Net is onely found in the heads of beasts, but we, saith *Bauhine*, haue beene able to make demonstration of it in all the mens heads we haue hitherto cut vp, although we confesse that in Calues and Oxen it is much greater & more conspicuous. Now these three particles, the Tunnell, the Glandule and the Net

The way how to demōstrate these parts.

cannot be demonstrated before the substance of the After-braine be taken away; and the 2. latter not before the *Dura meninx* be dissected. Finally, before you make demonstration of these three, you must shew the spectators the Mamillary processes and the payres or coniugations of the sinewes, which otherwise in the search for these will be defaced.

The

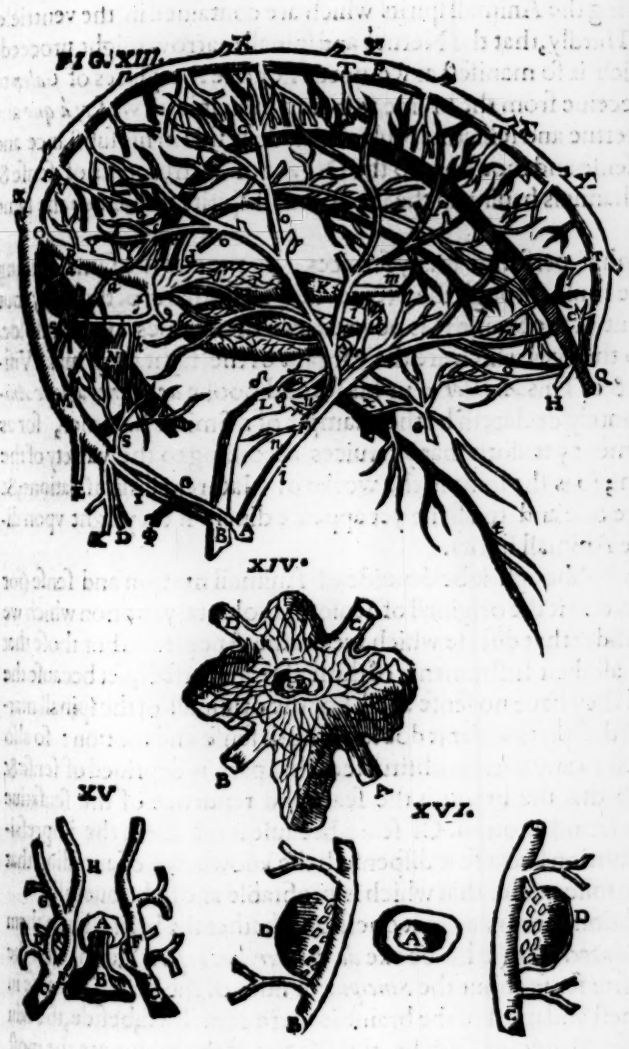
Table 13. Figure 13 exhibiteth the vesselles of the Braine and their distribation, especially through the right side, whither they proceede from the internall Iugular veine, or from the sleepie Arterie, or from the sinus *of the* Dura Meninx.

Figure, 14. sheweth the wonderfull Net as Galen describeth it.

Figure 15. sheweth the pituitary Glandule with the Bason and the sleepy Arteries.

Figure 16. sheweth the Rete-mirabile *or wonderfull Net, together with the glandule as it is found in the heads of Calues and Oxen.*

TABVLA XIII.



A. The internall Iugular veine.
B. The sleepy or Iugular artery.
C. the first veine.
D. the 2 veine which is led vnto the *Sinus*.
E, the 3, creeping through the *dura meninx*
F, the fourth running into the *Sinus*.
G H, the 5 and 6 going to the *dura meninx*.
I, the first Artery.
Φ. A braunch of the same Artery running through the Muscles of the necke.
K, the second artery reching into the *sinus*
L, the third without a companion.
r A small branch of the third Artery.
M, N, the 1 & 2 *sinus* of the *Dura Meninx*.
O, the congresse or meeting of both those *sinus*. PP, the *3 sinus* of the *Dura Meninx*
Q, The end thereof.
R, the fourth *sinus* of the *Dura meninx*.
SS, Branches of the first *Sinus* deriued into the Membranes neere at hand.
TTTT, Branches of the third *Sinus* dispersed into the *Pia Meninx*.
V V, the lower smal branches of the 3. *sinus*
X X, the vpper, distributed through the *Dura meninx*.
Y Y, certain surcles of the 4 *Sinus* sent vpward. *aa*, Others sent downward.
b, the vpper passage of the fourth *Sinus* running by the *Syth*.
cc, Surcles runing vpward from this passage
de, the right & lest vpper branches of the fourth *Sinus*, *f*, The lower branch going to the *Pia mater*.
g, A branch of the same pas: going forward
h, The same bending backewarde to the *Choroides* reflected to the *Cerebellum*.
i, A notable vessell into the which the 4. *Sinus* doth determine.
K the vpper. The by-partition of this vessel in the braine.
l, *m*, Two branches of this by-partition.
n. A surcle reching to the organ of hearing
ooo, the distribution of the 3 vein & artery,
ppp, Surcles proceeding from the Brãches marked with *o* derived into the *pia mater*
q, The diuision of the third artery where it entreth into the scull. *s*. A braunch reaching to the hollownes of the nostrils
t, the end of this in the extreamity of the vessel. *uu*, 2 branches entring into the scul
x. A branch deriued vnto the eie from the coition or meeting of the branches *uu*,
e, A branch attaining to the *pia mater*.
A, A brãch attaining to the right ventricle
Φ The complication of vessels called *Plexus Choroides* formed on either side of the scull, and making this wonderful net.

branch marked with A. *Fig.* 14. A, B, Arteries climbing. C D, Branches into which the surcles of that net are ioyned in to E, the pituitary glandule or kernel of flegm *Fig.* 15. A, the Glandule receiuing the bason. B, the bason it selfe, or if you wil, the Tunnel called *Peluis* or *infundibulum*. CC, the sleepy Arteries. D, A branch of the artery going to the side of the *Dura Meninx*. E, Another branch of the same artery going to the nostrils. FF, An artery in one side diuided into 2 branches, but in the other side meeting togither againe. G, A partition of the artery creeping through the *dura meninx*, H, Another branch which getteth out of the scull and reacheth to the eies. *Figure* 16, A The petuitary Glandule. B, C. The sleepye arteries going into the scull. D, D. The wonderfull Net.

For the vse of the Braine. *Aristotle* (in his second booke *de partibus Animalium* and the 7. chapter) writeth, that the braine was made as a commõ good for the behoofe of the whole Creature, to temper the feruour and heate of the heart; which opinion because it is sufficiently refuted by *Galen* in his 8. booke of the *Vse of parts* and the second chapter wee wil not insist The vse of the Braine.

insist long vpon it, only these two things we open. First, that the heart is sufficiently refrigerated by our perpetuall inspiration and expiration. Secondly, that if Nature had intended the brayne to coole the heart, she would not haue set them so farre distant, but placed it eyther about the heart or at least in the Chest: as well therefore might he haue saide that the Heele was made for the vse of the heart as the Braine:

Diuerse

Wherefore we determine the vse of the braine to be, first for a habitation for the soule whereby she performeth her Animall functions, as well those that are principall as also those of sense and motion. Secondly, that in the substance thereof the Animall spirits might bee laboured, therein conueyed and from thence deriued into the body. For so

Galen.

saith *Galen* (in his 8. booke of the *Vse of parts* and the 13. chapter, and the 9. booke and the 4. chapter.) In the whole substance of the body of the Braine is the Animal spirit wrought and reserued, not onely in the ventricles: and in his 12. booke of Method the 5. chapter & the third *de locis affectis* and the 7. speaking of the falling sickneſse he saith, It is caused in the braine, the humor hindering the Animall spirits which are contained in the ventricles that they cannot yssue out. Thirdly, that the Nerues and spinall marrow might proceede from the marrow thereof, which is so manifest as we neede not cite the places of *Galen* to proue it. For the Nerues receiue from the braine as from a principle, as we say *à quo* and of dispensation, the Animal vertue and sensatiue soule which do reside in his substance and do distribute the faculties of sense and motion into the Organs or Instruments of sense & motion as it were through Channels hauing in thē the Animall spirits to conuey the same faculties.

The Animall spirit.

This Animall spirit although it performe many seruices, is one and the same; leading all the faculties of the sensatiue soule through the Nerues into all the parts of the body: but the Instruments into which out of the braine it is powred into the Nerues are manifolde. Wherefore if they runne into the eyes which are the Organs of the sight they make Vision; if into the eares Hearing, &c. This *Aristotle* (in his second booke *de generatione Animalium* and the last text) elegantly declareth by the example of a Smiths hammer, for as the hammer is but one instrument yet doth many seruices according to the variety of the subiect vpon which it worketh; so is the spirit in the worke of Natures administrations; & as the beames of the Sunne are one and the same yet appeare diuers if they light vpon diuers coulers, so is it with the Animall spirits.

Aristotles Comparisons.

The seate of the sensatiue soule.

The substance of the Braine although it be deuoide of Animall motion and sense (for it is not deuoide of Naturall) yet is it the originall of sense and voluntary motion which we may better perceiue if we consider that disease which we cal the Apoplexie. For those that are Apoplecticall although all their Instruments of the senses are perfect, yet because the Animal spirits are intercepted they haue no sense at all. For the originall of the spinall marrow being totally stopped, all the parts vnder it doe loose both sense and motion: so also if the Nerue which is conueyed to any part be obstructed, that part is depriued of sense & motion. Hence it followeth that the braine is the seate and residence of the sensatiue soule, and the fountaine of sense and motion. Of sense, because it receiueth the impressions of all sensible things. Of motion because it dispenseth the knowledge of auoiding that which is hurtfull, and desire to follow after that which is profitable and behouefull.

Animall motion & sense.

Natural sense

As for Natural sense and motion there is a great question whether the braine haue them or no: and first for sense. *Hippocrates* (in his booke *de vulneribus capitis*) saith, that the braine hath present and exquisite sense about the *Sinciput* or sides of the head, because in this place the bone is the thinnest and most of the braine is there contained; beside, the skin of the head is there thinnest also. Moreouer saith he, the diseases of the braine are the most *acute* and dangerous, yea for the most part mortall and hard to be iudged of by those that are not very well experienced.

Galen.

Galen (in his first booke of the cause of *Symptoms* and the 8. chapter) saith, that the braine was not made by Nature an instrument with sense, but so that it is able to comprehend or perceiue all those things by which it suffereth, as if he should haue saide, The braine is not made to be a particular instrument of sence, so as it can perceiue or apprehend colours onely as the eyes, sauours onely as the tongue, &c: But it is a common instrument of sensation discerning colours, sauours, smels, sounds and tactile qualities; and in a word all sensible obiects.

Wherefore the braine feeleth vniuersally whatsoeuer is offered vnto it, not with choice as the eye which receiueth not the sound but onely his owne obiect and so in the rest. It

remai-

remayneth therefore that the Naturall ſence of the braine is none at all or at leaſt ſo weak and dull as it is hardly perceiued, for in his ſubſtance there is rather a faculty of Touching then an inſtrument of Touch.

Fernelius thinketh that all motion is from the marrow of the braine, and all ſence from his membranes; becauſe the body of the braine is perpetually moued but hath no feeling at all: on the other ſide, his membranes are of themſelues immouable eſpecially the *Dura mater*, but feele very exactly. So in the Lethargy or Phrenſie which are diſeaſes of the ſubſtance of the braine there is no paine at all, but if a ſharp vapour or humour be raiſed vp vnto the Meninges, then grieuous paine followeth. Moreouer the ſpinall marrow and all the nerues haue their marrow from the braine & that couered with the Meninges, al which haue the ſame and no other power or faculty then what they receiued from their original. wherefore the forepart of the braine is the beginning of Sence, the hinder part of Motion, but of Touching the Meninges or Membranes are the originall. Thoſe nerues which are full of marrow are the inſtruments of Motion; of Touching, thoſe whoſe greater parts are produced by the Meninges. And this is *Fernelius* his Philoſophy concerning this poynt, but how conſonant to reaſon we ſhall ſee afterward.

Fernelius his Philoſophy about this.

Concerning the motion of the braine great difference there is among Authors. *Galen* in his 8. booke of the *Vſe of Parts* and the ſecond Chapter, ſayth it hath perpetuall motion. *Veſalius* denies it, anſweres his arguments & addeth that he could neuer perceiue any ſuch motion either in great woundes of the head, or which is more in his diſſections of liuing Creatures. *Fallopius* halteth in this poynt, he ſayes it but hee dares not auouch it.

The motion of the braine.

Veſalius againſt *Galen*.

Platerus thinks that thoſe that ſay it moues, miſtake the motion of the braine for the motion of the third *Sinus*, which beateth like an artery. *Columbus*, *Archangelus* and *Laurentius*, doe all conſent that it moueth continually; and inſtance in woundes of the head. *Laurentius* is ſo confident that he ſayth he is a mad man and wants his ſences that will deny it. To reſolue vpon ſomewhat among ſo many opinions, we think; that the braine is not moued by any Animall or voluntary motion, but by a Naturall and that double: one proper of his owne, another from the arteries, albeit this laſt *Archangelus* doth deny, becauſe thoſe arteries that runne aboue are too ſmall, but thoſe that are in the bottom of the brain much leſſe, yet it giueth the power of voluntary motion to other parts.

Laurentius.

What we reſolue of.

This motion is proper and peculiar to the braine, for the generation, nouriſhment and expurgation of the Animall ſpirit, for it is dilated and againe conſtringed as may be ſeene in wounds of the head where a notable part of the Scull is taken away, as alſo of the membranes ſayth *Bauhine*. And in children new borne in the mould, the braine is ſo manifeſtly ſeene to beate and pant, that euen the bones which at that time are very ſoft are mooued therewith. When it is dilated it draweth out of the *Sinus* of the *dura mater* (ſome ſay out of the wonderful net or web of the *ſoporarte* arteries) vitall ſpirits and ayre by the noſthrils, for the reſtauration and preſeruation of the Animall ſpirites, & when it contracteth it ſelfe it driueth out the Animall ſpirits laboured in his ſubſtance through the nerues, as through pipes and canals into the organs of ſence and motion, or as *Archangelus* hath it out of the foreward ventricles being contracted into the third and fourth, and ſo into the organs aforeſaide: which ſpirites when they ariue in the particular parts they nouriſh the Animall ſpirits bred and fixed in thoſe partes. For the Animall ſpirit floweth through the nerues into all the parts, not onely to be the conuayer of the ſenſatiue and mouing Soule, but alſo to giue nouriſhment to the Animall ſpirits fixed in the parts; and this ſpirit is the *medium* or Meane by which the Senſatiue Soule and al his faculties which are incorporeal are ioyned with the body. The outward parts becauſe their inſtruments are farther off, ſtood in neede of nerues as it were Channels through which the Animall ſpirites accompanied by the Vital as it were by guides might be conuaied, but the inward parts becauſe their inſtruments are neare and at hand needed no nerues, but receiue the ſame by blind and inuiſible by-waies yet guided by the ſame Vital ſpirits.

The vſe of the motion.

How the motion is diſcerned.

The Animal ſpirits.

We haue alſo ſayd that at the entrance into and at the out-gate from the heart there are certain Values or floud-gates ſet, and their vſes wee haue allotted. Now *Archangelus* is of opinion that the Buttocks and Pine-glandule of the Braine doe here the ſame offices that the values did in the heart. For ſayth he, in the dilatation of the braine the way out of the third ventricle into the fourth cloſeth it ſelfe, and beſide is ſhut vp by the glandule falling betweene the Buttocks, that no part of the ſpirits can returne out of the fourth ventricle into the third. On the contrary, in the contraction the glandule is lifted vp and the Buttocks

A witty conceit of *Archangelus*.

are diuided, and so a way is made for the Animall spirit to flow out of the third ventricle into the fourth.

Diuers opinions of the generation of the Animall spirits.

Concerning the generation of Animall spirits there are diuers opinions; especially seauen, one of *Galen*, another of *Vesalius*, a third of *Columbus*, a fourth of *Argenterius*, a fift of *Archangelus*, a sixt of *Laurentius*, and a seaueth of *Varolius*, to which *Bauhine* our author subscribeth.

Galens.

Galens opinion was, that they were made of the vitall spirite brought by the *soporarie* arteries and of ayre breathed in, mary as for the place of their generation he seemeth to be altogether vncertaine; for sometimes hee assigneth the *Plexus Choroides*, sometimes the ventricles, sometimes the substance and body of the braine.

Vesalius.

Vesalius sayeth they are laboured in the right and left ventricle by a power and efficacy receiued from the brain, and haue for their matter vitall spirits from the heart, & aire drawn in by inspiration ascending through the third ventricle.

Columbus.

Columbus sayth they are made of ayre drawne by the nosethrils and altered in the cauities of the forehead bone and the wedge-bone, and carried through the pores of the spongy bone to the forward ventricles where it meeteth with the vitall spirit sent vpward from the hart by the *soporarie* arteries, & powred into the *Plexus choroides* which is in the ventricles; both which spirits and ayre, sayth he, by the perpetuall motion of the braine and this *Plexus Choroides* are exactly mingled, and of them the Animall spirits are generated in that *Plexus Choroides* which is in the ventricles, and this he sayth was his owne inuention.

Argenterius.

Argenterius will haue but one influent or moouable spirite besides the fixed spirites of the particular partes, whose arguments shall be sufficiently answered in our Controuersies by *Laurentius*.

Archangelus.

Archangelus opinion is, that the Animall spirits are made of the vitall, changed by many exagitations and alterations by the arteries which make the *Rete mirabile* and the *Plexus Choroides*, but receiuing his vttermost perfection in and by the substance of the Braine, & so becommeth a conuenient vehicle of the sensatiue soule. The processe of which generation he sayth is after this manner. There is an inchoation or beginning made in the *Rete mirabile*, but the plenarie perfection is in the *Plexus Choroides*, yet that from a power or faculty of the marrow of the braine in which alone such power resideth; being so perfected they are powred out into the ventricles (which adde nothing to their generation) as into store-houses or places of receyte where they are kept to bee transported into the whole body.

Laurentius.

Laurentius thus, the Animall spirit is generated of the vitall spirit and the aire breathed in; whose preparation is in the labyrinthian webs of the small arteries, & in the vpper or forward ventricles; but they receiue a farther elaboration in the third ventricle and their perfection in the fourth, and from thence by the nerues are diffused into the whole body: but he reprehendeth those that auouch that this spirit receiueth his forme and specificall difference in the webs before named.

Varolius.

What we resolue of.

Bauhine.

Finally *Varolius* and with him *Bauhine* and wee with them will resolue, first for their matter that it is arterial bloud aboundantly fulfilled with vitall spirits and ayre drawn in by the nosethrils; for the manner wee say it is thus. The spirituous and thin bloud is sent vp from the heart by the *soporarie* arteries vnto the braine, and is powred out into the *Sinus* of the *dura mater* whilest they are dilated as is venall bloud out of the veins. With this is mingled ayre drawne by inspiration through the nosethrilles, and ariuing into the braine through the pores of the spongy bone. These substances thus mingled and mixed in the vesselles, whilest they are carried through the conuolutions of the Braine are altered and prepared, purged also from phlegmatick excrement, which whilst it nourisheth the braine, the more subtile part is transfused into his substance, and there, that is, in the marrowy substance of the braine, it is laboured into a most subtile Animall spirite, and so is from thence by the same passages returned and communicated to the spinall marrow and to the nerues of the whole body. Neither saith *Varolius* is it necessary that these spirits should haue any cauities to be laboured in; and hee sheweth it by an example. When wee shut one eye the Animall spirit in a moment returneth vnto the other, so that it dilateth the ball or pupill of the other, and yet is there no manifest passage between them, sauing those insensible pores which are in euery nerue and also in the substance of the braine.

Platerus.

And hereunto subscribeth also *Platerus* on this manner: the common opinion saith he, is that the Animall spirit is generated and contayned in the *Plexus Choroides*, which I cannot approue as well because

cause these vessells are so very small, as also because so many excrements of the braine fall through the ventricles. I thinke therefore that the Animall spirit is tyed to the substance of the braine, so that the braine is neuer without Animall spirites, neither can the Animall spirites subsist in any part without the substance of the braine: for what else is the inward substance of euery Nerue but a kinde of production of the braine compassed about with a production also of the membranes of the same.

And thus much shall be sufficient to haue sayed concerning the vse of the Braine and the generation of the Animall spirit. Now wee proceede to the After-braine or the *Cerebellum*.

CHAP. XIIII. *Of the Cerebellum or After-braine.*

THat the whole Masse of the Braine is diuided into the Braine & After-braine we haue already shewed. The cause of this diuision *Varollius* taketh to be this. Whereas of those things which are apprehended by the senses there are two chiefe, differing much the one from the other yet both of them so immediately seruiceable to the vnderstanding that they cannot be substituted one for the other; wherof one belongeth to the Sight the other to the Hearing; and because there is required to the perfection of sight the mediation of a moist and waterish body as we see in the eyes; therefore for their behoose especially and of the visible Species which they admit, that part of the braine was made which is the softer and so great that it filleth almost the whole Scull; and this is called properly *Cerebrum* or the Braine. But because those Species which are apprehended by sound, or resounding; do require a kinde of drines in their Organ, as *Hippocrates* excellently acknowledgeth (for where there is only moysture there is little or no resonance at all): therefore vnder the braine in the backepart of the head there is ordained and scituated a lesser and faster portion which they call *Cerebellum* we the *After-braine* which as it is truely harder then the braine it selfe, so is it consequently dryer. And this is *Galens* opinion in the 6. chapter of his 8. booke *de vsu partium* where he saith; that therefore it is harder then the braine becausc it produceth hard Nerues; al- eit *Vesalius*, *Columbus* and *Archangelus* wil not admit any difference in their substances. Wherefore the Braine it selfe was especially made for the behoose of the eyes, & theyr obiects: the After-braine for the vse of resounding *species* or such things as were to bee represented to the hearing. And because the sight is more excellent then the hearing, ministring vnto vs more difference of things, therefore it is seated aboue the braine.

The reason of the diuision of the Braine.

Galen.

Vesalius.

Why the braine is aboue the after braine.

The *Cerebellum* or After-braine, called in Greeke παρεγκέφαλις and by *Aristotle* ἐπικρανὶς, that is *after the Braine*; is as it were a priuate and small Braine scituated in the backe and lower part of the scull vnder the Braine [Tab. 11. fig. 8. ᴿᴿ] from which it is separated: it is also couered with both the Meninges or Membranes, and is vnited to the spinal marrow for a little space where also it affoordeth a part out of it selfe to make the bulke of the same narrow.

The after-braine. *Aristotle.*

His connection.

In brute Beasts it is round and acuminated or growing sharpe and taketh vp almost all the backpart of the head. It is continuated on eyther hand to the sides of the Braine by two orbicular or round portions: [Table 11, fig. 8. neare ᴺᴼ.] But to the spinall marrow it is ioyned in the very middest, yet toward the backside, [Table 12, fig. 9.ᴿ] by the interposition of the *Pia mater*: And because the fourth ventricle should not there start open it is compassed with the thinne Membrane which is spred as farre as to the Buttocks. [Table 11, fig. 8. betwixt ᴼᴾ and ᵠ] It is separated from the braine that through the thicke Membrane the vessels might be securely conueyed into the depth of the braine.

The forme of it is broader then long or deepe, and in the lower and backpart it resembleth a flat bowle, in the middest whereof there is a sharpe impression ietting out from the bunch of the Nowle-bone; forward toward the buttocks of the braine it runs into a sharpe wedge hauing that figure because the place will admit no other.

The forme of the after-braine.

It consisteth of three parts, the right, the left, and the middle (which yet are not diuided but continuated) because of the bunch of the Nowle-bone, of which we shall speake more particularly hereafter.

The parts of it.

The right and the left parts are like two bowles set together, [Table. 12, fig. 9.ᴿᴰ] in the middest of which where the bowels do not touch, is placed the third part which is rounde and runneth as it were into a Ring from before backward, & maketh those processes which are called *vermiculares*. By reason of these parts it hath three-fold impressions, some ouerthwart

Table 14. figure 18. Sheweth the Head on the left side somwhat raised from the right side, as also a part of the Brain (the After-Braine being remooued) remaining, and a little eleuated and reflected backeward, that the Instruments of smelling might be discerned.

Figure 19. sheweth the Head set vpon the Nowle, that a portion of the Braine hanging backward, the Organs of smelling, the coition or meeting of the Optick Nerues and the Soporary Arteries might better appeare.

CC. Those swellings of the brain which are called the Mamillary processes.
D, E. The organs of smelling reflected togither with the braine.
FFFF. The two vpper shew the bosomes of the scull in which the Mamillary processes do rest, the two lower shewe the bosoms or cauities of the organs of smelling
G. A partition distinguishing these organes and their bosomes or cauities.
H. the 6 veine doth here enter into the scull.
I. The fift veine of the braine.
K. A vessell like a veine running out of the *dura meninx* into the *Tennis*.
LL. The beginning of those passages which run by the sides of the *dura meninx* ioyned to the arteries after the maner of Veines.
M N. The right and left optick nerues.
O. Their coition or coniunction.
P. A branch of the Soporary artery, perforating the Dura Meninx at the side of the Tunnell.
Q. A branch of the Arterie reaching to the right ventricle.
R. Another branch going to the *Pia mater*.
S. The Tunnel receyuing the Phlegm of the braine.

thwart and scored along through it; others running right downeward which are ioyned on eyther side as it were vnto a Center. For the lynes it hath are long and almost superficiary, yet diuided manifold and distinguished by the thin membrane running betwixt them. The reason why they runne in the superficies or surface only is, because if they did descend deeper as we see in the Conuolutions of the Braine it selfe, they would perforate the *Cerebellum* euen vnto the ventricle. They are also manifolde that their plenty might supply their superficiall course; as for those long and winding contortions which are in the braine, in this After-braine they are not to be found.

The Line.

Why superficiary.

The substance of it is almost the same with the substance of the Braine it selfe, if wee take it freed from the *Pia mater*, excepting in the Basis of the Braine where the spinall marrow beginneth, which is harder then all the other parts, yea then the After-braine it selfe.

The substance

For

Table 15. Figure 20. ſheweth the head turned vppon the Eare, that the inner Baſis of the Skull couered with the dura Meninx *might be ſeene, there is a ſo ſo much of the Braine and ſpinall marrow left, as ſerueth to exhibite the coniugations of the nerues of the Braine.*

N, the beginning and ſurcles of the ſixt paire of nerues.
O, the beginning of the ſeuenth paire of nerues.

Figure 21.

AB, the right and left part of the After-braine.
CD, the *anterior* and *poſterior* regions of the middle part of the After-braine.
E, the *anterior* wormy proceſſe.
F, the *poſterior* wormy proceſſe.
GG, In this place the After-braine did grow to the ſpinall marrow.
H, the cauity of the After-braine which with the cauity in the ſpinall marrow maketh the fourth ventricle.
IK, the *anterior* and *poſterior* proceſſes of the braine, called *vermi-formes* or the wormy proceſſes.

For this ſpinall marrow neither in colour nor in hardneſſe is anſwerable to the *Cerebellum*, becauſe the After-braine is yellower or rather more Aſh-coloured, being no where white but in the ſurface of his ventricle; but the ſpinall marrow is exceeding white, as alſo is the Baſis of the Braine which giueth beginning vnto it.

The quantity of the After-braine is much leſſe then that of the Braine. The Braine being as ſayth *Fallopius* foure times, as *Veſalius* would haue it, tenne times as bigge as the *Cerebellum*. The quantity.

In the middeſt thereof it hath a broad *Sinus* or hollowneſſe not very deepe, which maketh as it were the roofe or vpper ſide of the fourth ventricle, for the reſt of it is couered with the thin membrane; [Table 15. fig. 21. ⁿ] with in ward it hath no cauities as hath the braine, becauſe it neither aboundeth with ſo many excrements, and thoſe it doth gather, it eaſily turneth downe on the out ſide. The *Sinus*.

It hath two proceſſes (*Platerus* reckons foure) [Table 15. figu. 21. C D] which becauſe they are like to wormes in rotten wood, *Galen* in the 14. Chapter of his 8. Book *de vſu partium* calleth *vermi-formes excreſcentias*, VVormy proceſſes, one of which regardeth the foreſide, the other the back of that ventricle which is common to the After-braine and the *Platerus*. *Galen*. The wormy proceſſes.

ſpi-

ſpinall marrow. Theſe proceſſes are diuerſly orbiculated or rowled vp, conſiſting of many particles, not oblique or right but tranſuerſe, coupled together by the *pia mater* or thin membrane, whoſe end or top is embowed and thinne (which *Aurantius* calleth the *peake*) and entreth the cauity which they call the Ciſterne, yea into the fourth ventricle.

Aurantius.

Archangelus maketh this wormy proceſſe not as *Galen* would haue it, to be of the ſubſtance of the braine and a part thereof, but a long membranous body, being indeede nothing elſe but the *pia mater* corrugated or foulded together, which in the dilatation of the braine is neceſſarily extended: but in the contraction is corrugated or crumpled vp like a worme.

Archangelus his opinion of the ſubſtance of the wormy proceſſe.

For becauſe (ſayeth hee) the braines of thoſe that die are contracted and fall into themſelues, it neceſſarily followes that after death the membrane muſt in that part bee contracted.

It appeareth alſo thicker then otherwiſe the crumpled membrane would, becauſe being ſcituated in a low part, it receiueth the moyſture there collected and encreaſeth with that additament. VVherefore ſayth he the worme as it is a worme is of no vſe at all. But to returne.

The firſt proceſſe.

VVe ſayde theſe wormy proceſſes were two, the firſt which lyeth on the forepart [table 15. figure 21. C] neare the buttocks is thought by *Galen* in the 5. Chapter of his 9. Booke of Anatomicall Adminiſtrations, to keepe open the paſſage of the third ventricle into the fourth; albeit *Veſalius* taxeth *Galen* for aſsigning that vſe vnto it. *Galen* alſo in the 14. chapter of his 8. Booke *de vſu partium* ſayth further, that this proceſſe when it is extended ouer the foreſaid paſſage doth wholly obſtruct or ſtop the ſame; but if it be reflected backward and rowled vp, his imbowed parts do draw the membrane to them adioyned, and the paſſage is ſo farre opened as way is made by that retraction. For as it is reflected and rowled round, by howe much the length of it is diminiſhed by ſo much the breadth is encreaſed; wherefore it behoued not, that theſe proceſſes ſhould be either too thicke or too thin: not too thicke, for then they could not haue exactly cloſed the paſſages becauſe they ſhould haue had no ſlender parts which might haue inſinuated themſelues into the narrow ſtraits of the paſſages. Againe, if they had beene too thin, the paſſages before ſaid could neither haue bin exactly ſhut nor well opened.

Galens vſe of the wormy proceſſes.

And leaſt theſe proceſſes ſhould altogether fall into the paſſages, Nature hath on either ſide bound and conioyned them to the buttockes with ſlender bodies which the Anatomiſts call *Tendines* proceeding from the thinne membrane; which membrane being extended to the hinde-moſt ventricle maketh the end of this proceſſe. And this is *Galens* Anatomy concerning theſe proceſſes, and deſerueth well to be conſidered of, eſpecially if we make our diſſection of the head after the ordinary and accuſtomed manner.

The other proceſſe [table 15. fig. 21. FD] which is the hinder, and from behinde inclineth forward, doeth not beare out as the former did, but his poynt is rather hid in the ſubſtance of the *Sinus* of the After-braine.

The 2 proceſſe.

The vſe of the firſt is to vſher the ſpirits; of the ſecond that the way or paſſage of the fourth ventricle (which *Galen* in the 11. 12. and 13. Chapters of his 8. Booke *de vſu partium* calleth the ventricle of the *Cerebellum*) might not be obſtructed by the After-braine preſſing vpon it. But we are of opinion that this is the common vſe of both the proceſſes, becauſe this paſſage (ſo often now mentioned out of the third into the fourth vētricle) ought neuer to be ſhut but to remaine alwayes open that the Animall ſpirit might haue perpetuall free influence into the ſpinall marrow. *Platerus* thinkes that this vſe is common to all the foure proceſſes (for he reckoneth foure.) But *Veſalius* aſsigneth to them no other motion or office then to the reſt of the ſubſtance of the *Cerebellum*, but if you aske his reaſon, I thinke it was onely that he might gain-ſay *Galen*.

Their vſe.

At the ſides of theſe proceſſes we meet with two other portions which are continuated to the ſpinall marrow [table 15. fig. 21. GG.]

The vſe of the After-braine (as ſaith *Galen* in the 6. Chapter of his 8. Booke *de vſu partium*) is that from it the harder nerues might haue their originall: which notwithſtanding *Veſalius* and *Columbus* doe deny. *Archangelus* and *Platerus* eſteeme it to be of the ſame nature with the braine and adorned with the ſame faculties. *Galen* thinketh that the Animall ſpirit being contained in the whole ſubſtance of the braine, not only in the ventricles thereof, is in great quantity treaſured vp in this After-braine, as being to be the original of all the ſinewes which were to bee diſtributed into the whole body: and that thoſe middle

The vſe of the *Cerebellum.*

dle diſtances which tye together the parts heereof, are the paths and wayes wherein the Animall ſpirits diſport themſelues.

Finally, *Varolius* conceiueth, (which we partly touched before) that the Braine was e- *Varolius.*
ſpecially made for the eyes and the viſible obiects. The After-braine for the eares and reſemblances of ſounds to be conueyed vnto them.

CHAP. XV. *Of the ſpinall Marrow or pith of the Backe.*

THE name of Marrow is properly attributed to that ſubſtance which is ſimple and vniforme, moiſt, fat, white, without ſenſe contained in the Cauity of bones and hath his original from the bloud; which through the veines ſlideth by ſecret pores and paſſages into their hollowneſſe or ſpungy ſides. It becommeth white and as it were ſpermaticall by a mutation it receiueth from the bones, becauſe in them it is ſtored to be their proper nouriſhment and to refreſh them when they are heated and dryed by motion or other violent cauſes. What true marrow is.

But of this marrow we do not intreat at this time: the name is improperly giuen to the Braine alſo and the pith of the Backe: For the Braine it ſelfe is called μυελὸς ἐγκεφάλου *medulla cerebralis* the Marrow of the Braine, becauſe ſaith *Plato* the ſubſtance thereof is marrowye, although there be great difference betweene them, for that it will not melt and conſume as marrow doth, and beſide is inueſted or clothed with both Membranes the thicke and the thin *meninx*. Why the Braine is called marrow. *Plato.*

Moreouer to diſtinguiſh it from ordinary marrow, it is called by *Galen* ῥαχίτης *Spinalis*. By *Hippocrates* in his book *de Carnibus*, νωτιαῖος *Dorſalis*, by others *Ceruicalis* and *Lumbaris*, becauſe it deſcendeth through the Neck, the Backe and the Loynes, and filleth the whole ſpine or Ridge-bone. The names of the pith.

Now there is a double acceptation of the Spinall marrow, for in the larger ſignification it ſignifieth the whole marrow of the Brain lengthened out, one part wherof is yet contained in the Scull, [Tab. 17, fig. 1. from ᴰ to ᵀ] the other continuall with the former yſſueth at the great hole of the Nowle-bone and deſcendeth to the very end of the ridge. [Tab. 16. fig. 1. from ᴬ to ᴮ] A double acceptation of the ſpinall marrow.

But in a ſtrict & more proper acceptation it betokeneth that part of the marrow which without the Scull is contayned in all the racke-bones or *vertebræ* of the ſpine or chine. [ta. 16. fig. 1. is an expreſſe Image of it] Wherefore that it may bee free from all ambiguity, the hiſtory thereof is on this manner.

That which is commonly called the Braine, that is, the whole ſubſtance included within the Scull we haue diuided into the Shell and the Kernell or Marrow. For theſe two differ in colour and conſiſtence. That which on euery ſide compaſſeth the marrow is Aſh-coloured; the marrow it ſelfe is white and of a more ſolid, faſt and compacted ſubſtance: and theſe two parts in greene or freſh heads are diſtinguiſhed by many oblique lines, ſo that with a rayſor they may be ſeparated if a man haue a ſteddy and cunning hand, yet not without breaking both the ſubſtances; ſo that *Archangelus* ſaid well, that the white was drowned in the Aſh-coloured as the chriſtalin humor of the eye is in the glaſſie; and as the glaſſie humor is eſteemed to be the Aliment of the chriſtaline, ſo the Aſh-coloured ſubſtance may well be thought to be the foode of the white, becauſe the Aſh-coloured appeareth ſo to be by reaſon of innumerable veines diſſeminated through it. The parts of the Braine. *Archangelus.* An elegant Compariſon.

The marrow it ſelfe may be ſaid to be double, one Globous or round, the other Long. The Globous part which is like the figure of the Scull, is of a great bulke and therein are ventricles excauated or hollowed. At this and continuall with it hangeth the other called *Cerebellum* of which we haue intreated in the Chapter going before according to the receiued opinion of Anatomiſts. The marrow double. Globous.

The Long marrow of the Braine which is like a Pith or ſtaffe may bee diuided into that part which is contained within the Scull, and that which is yſſued out which properly is called the ſpinall marrow; although ſome there are that giue this name vnto all the Long marrow of the Braine as well within the Scull as without; and this is it of which wee now ſpeake. Long.

The Spinall Marrow therefore according to this large ſignification taketh his beginning (as *Galen* ſaith in the tenth chapter of his 8. book *de vſu partium*) from the backe ventricle of the Braine; for he thought it nothing elſe but the Braine lengthened, which may ſeeme to agree with the Scripture which calleth it *The ſiuer cord*. And this, hee ſaith in the twelth The originall of the ſpinal marrow. Eccleſiaſtes.

twelfth chapter of the former booke, is continuated onely with the Braine at the Basis thereof.

Diuers opinions. There be many opinions of the originall of this spinall marrow, we will reckon vnto you the most notable.

Hippocrates opinion. The first is that of *Hippocrates* in his booke *de Carnibus*, where he saith in general words that it ariseth from the Braine. *Galen* more particularly and distinctly from the hinder ventricle of the Braine. The common opinion is that it ariseth out of the *Cerebellum* or After-braine. *Vesalius* saies from the Basis or foundation of the Braine. *Archangelus* from the Globous part of the marrow of the Braine, betwixt the Braine it selfe and the *Cerebellum*; for those that say it hath a double beginning say as much as nothing. *Platerus* thinketh that it proceedeth like a new Long Braine from the Basis of the other and receiueth increase of strength from the *Cerebellum* also. *Columbus* saith it is nothing else but a Long Braine hauing a double beginning, the one greater from the braine it selfe, the other lesser from the after braine. The beginning it hath from the braine is but single, that it hath from the after-braine is double and as it were forked into a right and a left. The greater originall is from the forepart of the braine but a little distant from the Region of the Opticke sinewes, and therefore, saith he, I am constrained to confesse that the 3, 4, 5, 6, 7, and 8. paires of sinewes do not arise from the braine but from the spinall marrow.

Galen. The common opinion. *Vesalius.* *Archangelus.* *Platerus.* *Columbus.*

Varollius. *Varollius* who indeed was excellent in diseeting of the head saith, that there yssue from the braine and the *Cerebellum* foure roots making one notable trunke which they call the spinall marrow, out of which do yssue Nerues deriued vnto all the parts of the body. *Laurentius* is also of the same opinion. The truth is, that it is a production as well of the braine it selfe as of the after-braine out of which it proceedeth as a stemme from the roote, which we shall more particularly shew afterward.

Laurentius.

The scituatiõ and proportion thereof. This spinall marrow lying vnder the *Cerebellum* to which it is continewed, taketh vp that hollownes of the Scull which is aboue the great perforation or hole in the bone of the Nowle or backpart of the head; and the beginning thereof for the length of foure fingers breadth cleaueth to the braine within the Scull, [Table 17, fig. 1. from ᵖ to ᵗ] the latitude and depth of that originall are so æquall that it appeareth almost circular neere the quantity and forme of an Hens Egge as *Archangelus* saith; and from this originall those Nerues which are accounted the proper sinewes of the braine together with the Organs of smelling are produced and deriued into the Instrument of the fiue senses as *Varollius*, *Platerus*, *Archangelus*, *Laurentius*, and *Dominicus* do ioyntly agree.

The spinall Marrow properly so called. But the spinall marrow properly so called or the other part of it which is continual with the former [Table 16, fig. 1.] is wholy without the Scull. For when the marrow of the braine now lengthened attaineth vnto the great perforation in the Nowle-bone [Tab. 13, fig. 17.ᵗ] it discendeth and passeth along through the holes of the racke-bones euen to the end of the *os sacrum* or holy bone. It passeth I say through the bones themselues, least being soft and like the substance of the braine as *Galen speaketh*, it should in the length of his production suffer violence by those things which might light vpon it, whereas now the bones are as it were a safe conduct and firme defence thereunto all the way that it passeth.

Galen.

His course.

And hence it is, that the *Gracians* call this perforated part of the spine, ἱερὰν συρίγγα *sacram fistulam* the holy pipe. Sacred or holy because it containeth a principall part, and a pipe because it is as it were fistulated or bored, through which Cauity such a substance is transported as where from all the other Nerues are produced.

It is inuested or clothed with three membranes which *Hippoc.* in his booke *de Arte* calleth ἴλυτρα. The first of which, according to *Galen*, ariseth from a strong ligament exactly fastening the foreparts of the *vertebra* or rackebones, which ligament in the backpart determineth into a Neruous and strong coate, least in the bending or extention of the spine it should be broken or offended by the bones; because it is contained not as the braine in any immouable bone, but in rack-bones, which are not only moued but also sometimes somewhat dislocated. Wherefore the Nerues also which arise from the spinall marrow properly so called (least they should bee offended by the hardnes of the bones through which they passe) are clothed beside the two Menings with this third coate also.

The 3. Membranes of the Marrow. The first.

The vse of the humor. About this is a thicke and slimy humor powred, as also about all the ioynts and parts that were to be moued; least being ouer dried they should suffer paine, and so their actions or functions be interrupted; which wisedome of Nature men doe imitate when about the Axeltrees

Axle-trees of Carts and Coaches they ſmeare a ſoft and *viſcous* greaſe that they might more currantly moue.

The ſecond membrane ariſeth from the *dura mater* or hard Meninx; the third from the *pia mater* or thinne Meninx [Tab. 16. figure 1. expreſſeth the coates ioyned together] which two are not ſeparated as they bee in the braine: moreouer the thicker ſecureth the marrow from the bones, the thinner infoldeth his veſſels and cloſely bindeth together his ſoft ſubſtance, for through the thinne membrane the veines and arteries which nouriſh the marrow and ſupply it with vitall ſpirites are conuayed; which veſſelles we haue obſerued to proceede from the veines and arteries of the loynes as wee haue already ſhewed in the third Booke. The ſecond and third Membrane. The veſſels of the marrow.

The ſubſtance of this ſpinall marrow is all one with that of the Baſis of the braine, or rather of the globus marrow. VVherefore it is ſomewhat hard, compacted and white, yet ſo that it is much harder then the braine it ſelfe. And *Galen* in diuers places of his ninth Booke *de vſu partium* ſayth, that this ſpinall marrow is the originall of the harder nerues, as the forepart of the braine is of the ſofter; for to the ſtrength of motion a harder production was more behoofefull; and for the exactnes of ſence a ſofter. Note againe that the further it is diſtant from the braine, by ſo much it is harder and more compact; neither is it anſwerable to the colour and hardnes of the *Cerebellum*. For the *Cerebellum* or After-brain is onely white in the ſurface of his ventricle, other-where it is yellowiſh or Aſh-coloured; but the ſpinall marrow is very white moſt like to the marrow of the braine, ſauing that it is without any contortions or conuolutions, becauſe it is made onely to receiue and not further to labour that it hath receiued. His ſubſtance. *Galen.*

VVith the Braine it hath theſe things common; firſt his ſubſtance; ſecondly that it is an originall of ſinewes (*Ga.* addeth of all ſinewes) and is compaſſed with both the Meninges. Yet heerein they ſay it doeth not communicate with it, becauſe the braine (though it bee contayned within an immouable bone) yet beateth and is moued; wheras this marrow albeit be contayned within mouable ſpondels or rack-bones is not it ſelfe at all moued. But if that motion bee in the ſubſtance of the braine by an in-bred faculty, and the ſpinall marrow hath the ſame nature and ſubſtance that the braine hath, me thinks it ſhould bee reaſonable that this marrow ſhould be moued in like manner as the braine is moued, albeit our ſence is not apprehenſiue of it. And truely *Archangelus* conceiueth that it hath a motion, and when it is dilated receiueth Animall ſpirits from the fourth ventricle, and when it is contracted powreth them againe forth into the nerues which ariſe there-from. What it hath common with the Braine.

The figure of it is long, thicke and large at the originall, [Table 17. figure 1. from ᴰ to ᴵ tab. 16. fig. 2. from ᴬ to ᴮ] and though being gathered together it become ſomewhat narrower, yet is it not (as ſome thinke) by little and little continually attenuated till it come to the extremity of the *os ſacrum*: for as far as the *vertebræ* of the loynes [table 16. fig. 1. from ᴵ to ᴷ] it keepeth an equall thickneſſe almoſt; although *Galen* and *Veſalius* did thinke that it was conſumed as it ſent more nerues out from it. *Fallopius* in his obſeruations and *Platerus* doe not thinke that it groweth leſſe at all. Yet we muſt needes acknowledge that we find it fuller & thicker in the neck whence thoſe great nerues iſſue which are diſperſed through the armes, [Table 16. fig. 1. from ᴵ to ᴷ] and in the loynes whence proceede the great nerues of the loynes which deſcend vnto the thighes; [tab. 16. fig. 1. from ᴵ to ᶜ] and that afterward when it commeth nearer to the *os ſacrum* his marrowy ſubſtance is ſomewhat abated. The figure.

A cauity or *Sinus* there is formed in it preſently after his originall whileſt it yet remaineth within the Skull; which is like a writing pen, and therefore it is called *Calamus ſcriptorius* [Table 12. fig. 10. ᴷᴸᴺᴼ] for it is hollowed into a poynt or neb becomming leſſe by degrees, becauſe in that place there are no more excrements. His cauity. *Calamus ſcriptorius.*

This cauity maketh the middle part of the fourth ventricle of the braine; for the reſt of the ventricle is formed by the After-braine [table 15. figure 21. ᴺ] at which place the After-braine is ioyned to this marrow. [Table 15. fig. 21. ᴳᴳ is ioyned to ᴮ ᶜ as alſo in the 12. tab. and fig. 10.] *Archangelus* conceiueth that this cauity is vnder the fourth ventricle and continued with it, and that out of the fourth ventricle into it the Animall ſpirits doe flow, and that from this cauity they are diſtributed moſt what into all the fiue ſences. *Archangelus.*

And although the marrow be but ſingle and ſeemeth to haue no manifeſt cauity, yet in the very middeſt it is deuided into two parts by the thinne Meninx as far as to the rack-bones of the loynes; ſo that on either ſide there appeareth a little cauity which may not onely be demonſtrated in the marrow of an Oxe if it bee lightly boyled, but alſo as ſayeth

Table 16. Figure 1. ſheweth the true forme of the ſpinall marrow properly ſo called, together with his membranes & the nerues proceeding from the ſame.

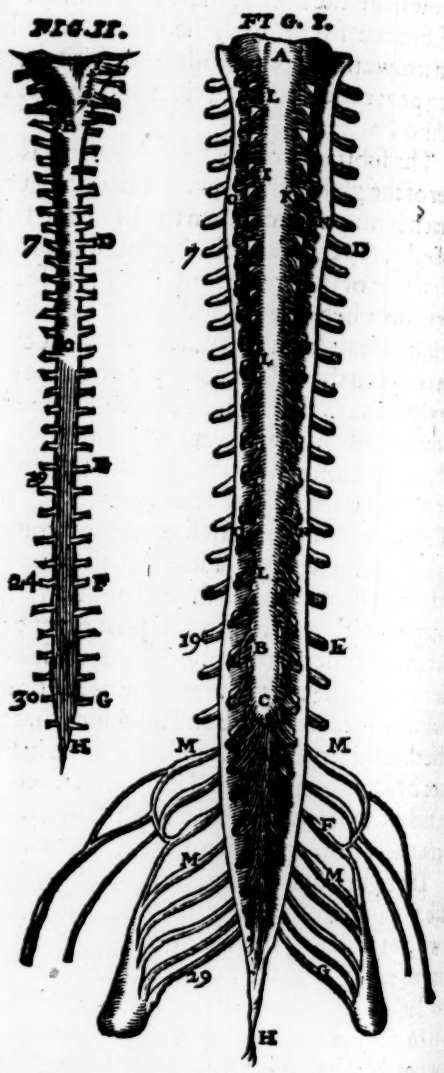
Figure 2. ſheweth the ſpinal marrow naked & bare, as it appeareth both within the skull & without, together with his nerues as moſt part of the Anatomiſtes heretofore haue deſcribed it.

TABVLA. XVI

A, The beginning of the ſpinall marrowe where it fals out of the skull.
B, the thickneſſe thereof in the ſpondels or rack-bones of the loynes.
C, the diuiſion thereof into ſtrings, or hairy threds.
D, the ſeauen nerues of the necke.
From D to *E* or from 7, to 19, ſhewe the nerues of the backe.
From *E* to F, the nerues of the loynes,
From F to G, the nerues of the *os ſacrum*, or holy bone.
H, the end of the marrow.
IK L, doe ſhew howe the nerues doe yſſue from the marrow in ſtrings.
MM, the knots of the ſinewes made of the coniunction of thoſe ſtrings.
NO, the membranes that inueſt the marrow.

Figure 2.

A, the beginning of the ſpinall marrow in the skull.
3,4,5,6,7. Theſe Characters ſhew (according to *Veſalius* opinion) how the cõiugations of the nerues of the braine doe take their originall from the marrow remayning yet within the skull.
B, the egreſſe of the ſpinall marrow out of the skull.
C, the cords or ſtrings whereinto it is diuided.
D 7, the marrow of the neck and ſeuen paire of ſinewes.
E 19 twelue pairs or coniugations of nerues proceeding from the marrowe of the Cheſt.
F 24, the marrow of the loynes and 5. paire of ſinewes.
G 30, the marrow of the holy-bone and 6, paire of ſinewes.
H, the extremity or end of the ſpinall marrow.



Platerus in a mans, becauſe it may bee parted aſunder without laceration. *Archangelus* thinks this cauity to be ſufficiently manifeſt to the eye; we are ſure to the vnderſtanding it is moſt apparant, by that we finde in thoſe that are troubled with the Palſie, in whome ſometimes one ſide ſometimes another is alone affected. Howſoeuer the marrow appearing ſimple and vndeuided paſſeth through the whole necke and the Cheſt euen vnto the loines and lower; [Tab. 16. fig. 1. from ^ to ^] and in his paſſage it ſcattereth nerues out of his ſides: afterward, that is, at the reſt of the loynes it is no more ſimple but deuided into many ſmal threds and filaments, very much reſembling a horſe tayle and ſo runneth on to the end of the *os ſacrum*. For as it began with the ſpine (wee meane the marrow properly ſo called) ſo it determineth therewith, ſometimes ſimple ſometimes deuided into three ſhort ſurcles. For it was neceſſary that in that part where the ſpine was eſpecially curued or bent backward or forward, it ſhould be diuerſly diuided that it might not be compreſſed by the *vertebræ*. Hence the reaſon appeareth why a hurt or annoyance in the lower part of the ſpinall marrow is worſe and more dangerous then in the vpper, becauſe below it is more Neruous aboue more marrowy.

How it may be ſaide to be deuided and where.

Whereof his nerues are made & how they yſſue.

Now although the Nerues yſſuing from the ſpinall marrow be almoſt infinite, yet according to the number of the out-lets or holes of the *vertebræ* they are ſaid to be ſo many coniugations as the *vertebræ* haue holes. For euery Nerue doth indeed conſiſt of many hairy ſtrings or marrowy fibres, which by the helpe of the Membranes at the holes of the

ver-

vertebræ are conioyned and making as it were a knot do yssue out of the bone, so that one Nerue seemeth to be made of one propagation. [Table 16. the first figure sheweth it at ll] which thing as it is true in those Nerues which proceede out of the Marrow whilest it is simple and single, so is it also in them which after the diuision are distributed into the lower parts. [Table 16, fig. 1, at mm].

To put an end to our discription of the spinall marrow, we will take leaue to insert in this place a description therof out of *Rondeletius* and *Laurentius*: which is on this manner *Rondeletius.* All the Nerues, (saith *Rondeletius*) which no man before me hath obserued, are diuided frō the very beginning of the spinall marrow in the Brain. Wherfore the cause of the Paralysis or Palsie doth not so much proceed from the marrow of the backe as from the very heads of the sinewes; & thence it is that *Galen* so often repeateth that the Palsie hapneth when the heads of the sinewes are eyther obstructed or resolued. Thus *Rondeletius* hath it in his chap. of the Palsie. *Laurentius* thus: All Anatomies haue hitherto beene ignorant of the origi- *Laurentius.* nall and propagation of the Nerues of the spinall marrow; for they al thinke that the nerues of the necke come onely from the marrow of the necke; the nerues of the backe from the marrow of the backe, and of the Loynes from the marrow of the Loynes. But how miserably they haue bin mistakē, is conuinced by a new and vnheard of obseruation of mine own. Separate therefore the marrow from the rack-bones but keepe it whole, then take from it both the Membranes wherewith it is compassed, cast it into water and shake it a little, and you shall perceiue that the whole marrow from the top to the bottome is made of innumerable surcles and filaments, like a Horse tayle composed of infinite hayres; and that the nerues of *os sacrum* do arise from the same beginning with the nerues that are aboue. This new and admirable obseruation maketh plaine an obscure probleme, why, when the marrow of the neck is offended the motion of the thigh is sometimes taken away, when as the motion of the armes and of the Chest is not at al vitiated; thus far *Laurentius*. To conclude. *A hard probleme explained.*

The vse of the spinall marrow properly so called, is saith *Galen* in his twelfth booke *de vsu partium*, that from it as from one other brain there should proceed many nerues as it were small riuerets which might conuey the Animall faculty, sense, motion and the Animall spirit; which they receiue by continuation from the braine (to the parts vnder the head) excepting those whereto are transmitted certaine propagations from the first payre [table 17 fig. 1, and 2, e] of the marrow of the braine, which also are disseminated through the middle and lower bellies. For, because it was not safe, in consideration of the length of the way, that all the nerues should be transported vnto the inferior parts from the marrow of the braine contained in the Scull; and yet it was necessary that those inferior parts should be supplyed with voluntary motion and sense to apprehend annoyances: it was most requisite that from this marrow, as from the braine elongated or produced, those sinewes should be deriued; for if a man had wanted motion hee had beene more like an Image then a creature. And thus much of the vse of the marrow properly so called. But if you take it in the larger signification, then the vse of it is, that from it where it is included within the Scull on both sides should yssue seauen Coniugations or payres of nerues, (as is commonly thought) we say eight, which are called the nerues of the braine, [table 15, fig. 20, BONIXMNO] together with the Organs of smelling. [table 14, fig. 19, pp]. But as it consisteth in the spine without the Scul there are produced there-from thirty paire [table 16, fig. 1] euen al the nerues that passe through the whole body. And thus much of both the braines and the spinall marrow, now it followeth that we should intreat of the nerues yssuing there-from. *The vse of the spinall marrow*

CHAP. XVI. *Of the Nerues of the Braine, and first of the Organs of smelling, called Processus Mammillares.*

THE Nature of the Braine, the After-braine & the Spinall Marrow being thus manifested, it remaineth that we should speake of the Nerues proceeding frō each of them; and first of the Nerues of the braine. Whereas therefore there are fiue outward senses, the Sight, the Smell, the Hearing, the Taste and the Touching, which from the braine it selfe or rather from the Marrowe thereof doe receiue by nerues as it were by Channels some of them the faculty of Sensation alone, some of them of Sensation and motion together, which nerues are sayed thence to arise as from a principle of dispensation & radication, from whence they bring the Sensitiue and mouing faculties of the Soule to the instruments of the Sences: it is very fit that in this place we should deliuer their history. Wee will therefore begin with the Organs of smelling. Although the Nose be the way & path of sinels, yet is not the instrument of smel- *The 5. senses. and their nurs.*

ſing, neither yet his blodmoſt coate, but farther within the skull there are certaine proceſſes or productions eſteemed for the very organs of this ſence, which the Anatomiſts looking onely vpon their prominent part haue called *Proceſſus mammillares*, and ſome the organs of ſmelling. Vnder which Title *Galen* hath written of them at large. Theſe are two ſome thing like nerues but ſcituated in the Baſis of the braine; they are whiter, ſofter and broader then nerues are. Notwithſtanding like nerues they are round and ſlender. In men they are very ſmall; in beaſtes as Oxen, Goates, Sheepe and Dogges they are much larger; whence it is that all theſe Creatures haue this ſence of Smelling more exquiſite then men.

Why beaſts ſmell better then men. Their originall.

Theſe proceſſes ariſing out of the marrowey ſubſtance of the braine in his Baſis [tab. 17

Tab. 17. *Fig.* 1. *Sheweth the Baſis of the Braine and After-braine freed from their membrane that the originall of the Nerues of the brain might be better perceiued.*

Fig. 2. *Sheweth one ſide of the Braine the After-brain, the ſpinall marrow and the Nerues.*

TABVLA. XVII.

FIG. I.

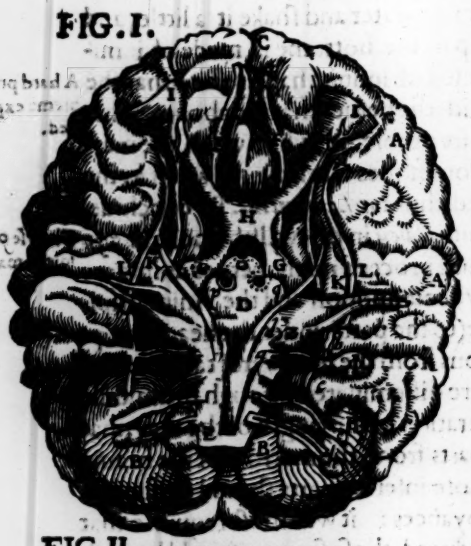


FIG. II.

A A 1,2. The braine.

B B 1,2, The After-braine.

C C, 1,2, the ſwellings of the braine which ſome call the mammillary proceſſes.

D, 1, the beginning of the ſpinal marow out of the Baſis of the braine.

E 1,2, a part of the ſpinall marrowe when it is ready to yſſue out of the skull.

F F, 1,2, the mammillary proceſſes which ſerue for the ſence of Smelling.

G G 1,2, the opticke nerues.

H 1, the coition or vnion of the optick nerues.

I I 1,2, the coate of the eye whereinto the optick nerue is extended.

K K 1,2, the ſecond paire of ſinewes ordained for the motion of the eyes.

L L 1,2, the third paire of ſinewes, or according to moſt Anatomiſts the leſſer roote of the third paire.

M M 1,2 the fourth paire of ſinewes, or the greater roote of the third paire.

N 2, a braunch of the third coniugation deriued to the muſculous skin of the forehead.

O 2, a branch of the ſame to the vpper iaw.

P P 2, another into the coate of the noſethrils.

Q 2, another into the temporall muſcle.

R 2, a branch of the fourth coniugation crumpled like the tendrill of a vine.

S 2, a branch of the ſame reaching vnto the vpper teeth and the gummes.

T 2, another of the ſame to the lower iaw.

V 2, a Surcle of the branch, T to the lower lip.

X X 2, other ſurcles from the braunch T to the rooters of the lower Teeth.

Y Y 2, the aſſumption of the nerue of the fourth coniugation vnto the coat of the toung.

Z 1,2, the fourth paire vulgarly ſo called, which are ſpred into the coate of the pallat.

α 1,2, the fift paire of ſinewes which belong to the hearing.

ρ, the *Auditory* nerue ſpred abroade into the cauity of the ſtony bone.

* a hard part of the fift coniugation aboue the * which may accounted for a diſtinct nerue.

b 1,2, a ſmall braunch deriued from this harder part of the fift payre.

c 1,2, a lower branch from the ſame originall.

d 1,2, this nerue is commonly aſcribed to the fift paire, but indeede is a diſtinct coniugation, which we will call the Eight, becauſe wee would not interrupt the order of other mens accounts.

e 1,2, the ſixt paire of ſinewes. *f* 2, a branch from them deriued to the necke and the muſcles couched thereupon, *g* 2, another branch to the muſcles of the larynx or throttle. *h* 1,2, the ſeauenth paire of ſixe ewes. *i* 1, the vnion of the ſeauenth paire with the ſixt, *l* 2, a propagation of the ſeauenth paire to thoſe muſcles which ariſe from the appendix called *Styloides*. *m* 2, Surcles from the ſeauenth coniugation to the muſcles of the toung, the bone *Hyois* and the Larynx. *o p q* 1, three holes; through the hole *o* the phlegme yſſueth out of the third ventricle of the braine to the Tunnell, and at *p q* is the paſſage of the *ſeparate* arteries to the ventricles of the braine.

fig.

fig.1.& 2.[F] tab.14.fig.19.[DF]], neare the optick nerues [tab.17.fig,1,2.[G]] do passe betwixt the braine, (whereto they are tyed by the mediation of the *pia mater*) the wedge-bone and the bone of the forehead vnto the *Sinus* or cauity of the spongy bone; [tab 14.fig,19.[H F]] which cauities are couered with the *dura meninx* diuersly perforated & are made to receiue these productions. To each of these processes saith *Fallopius* reacheth a manifest hole from the ventricle, from which hole the passage is open to the spongy bone. This passage in a man is very narrow, so that it cannot be discerned, but when the head is very greene or new. In Oxen it is very large. Through these passages & productions aire and vapors attracted or drawn in respiration through the nosthrils as it were by pipes and channels, are carried vn to the braine that it might iudge of odoriferous obiects. *Varolius* is of opinion that from these productions there is no free passage vnto the ventricles themselues; although *Fallopius* was vtterly of another minde. They are like to nerues in their passage, colour and vse, and therfore do well deserue to be called the *Nerues of smelling* as *Archangelus* stileth them. But *Vesalius* counteth them to be the first paire or coniugation of the braine; yet because they neuer attaine through the thicke membrane and cauity of the skul, neither haue as other nerues any propagations deriued from them: therefore neither *Herophilus* nor *Marinus* nor *Galen* himselfe, nor many amongst the *Neotericks* or new writers haue vouchsafed them the name of nerues; wee stand not vpon wordes and therefore passe from them vnto the nerues of the eies.

Fallopius.

Their vse.

How they may be called nerues.

CHAP. XVII. *Of the nerues of the Eyes, or of the first and second Coniugations.*

ALbeit in a particular discourse hereafter following wee intend more districtly and carefully to prosecute the Nature and diuarications of nerues in generall and euery one in particular; yet because all the nerues of the head haue their originall from diuers partes of the substance of the same: Wee cannot chuse in this place but make some mention of them though it be the briefer.

The optick nerues.

The first coniugation therefore of the nerues of the braine are the Opticks, [Table 17. figure 1.and 2.[G]] larger and softer then all other simple nerues. Larger because they bee sensibly perforated, softer because they arise out of the Center of the Basis, whence proceeding forward with a slow course they are vnited aboue the saddle of the wedge-bone [tab. 17.figure 1.[H] table 14. figure 19.[G]] and so make a common body. After being againe separated [Table 14.figure 19.[M N] Table 17.figure 1. aboue [M]] they passe obliquely foreward through their proper hole] table 4.figure 10.[B]] the one to the Center of the right eye, the other to the Center of the left [ta.3.lib.8.fig.8.[a] or together with the membrane fig.2.[abc].]

Their double substance.

They consist of a double substance, the one marrowey the other membranous. The marrowey is soft like the substance of the braine, which you shall perceiue to yssue if it bee hard pressed, and of this marrowy substance dilated in the orbe of the eye is that coat made which of the similitude of a net is called *Retina tunica* [Tab.17.fig.1 and 2.I] and this compasseth the glassy humour like a sphere.

Marrowey.

Their membranes.

It hath two membranes from the two Meninges of the braine. The thin membrane inuesteth it from the originall to his out-let from the skul; the thick Meninx is added to it, frō thence to the eye; and so the thicke membrane degenerateth into the horny coate, the thin is consumed or spent in the *Vuea*, and so the Animall spirit is transported through the continuation of this nerue vnto the *pupilla* or Apple, which is the hole of the grapie mēbrane.

They are called therefore Opticke nerues from their action, because they communicate to the eye the sence of seeing.

The second coniugation is of the nerues which moue the eyes, [table 18.figure 1.and 2. [F] tab. 15.figure 20.[G]] which is distinguished from the former only by a little and thin bone, and riseth from the Basis of the braine [tab.25.fig.1.[C]] a little behinde the former as *Vesalius* saith. This is smaller and slenderer by much then is the optick, as also harder because it was to be inserted into the muscles. It yssueth by a proper hole of his owne [tab.4.fig.10. [G]] which is the second of the wedge-bone, where after it is diuided into notable braunches which are sent into the muscles. In some bodies (though it be but seldom) they send small twigs to the temporall muscles; whence it is that sometimes if that muscle be offended the eie also suffereth with it, and so on the contrary.

The 2. coniugations of the mouing nerues.

Their frame.

Note this.

Their vse is to afford to the muscles the facultie of Motion, as also a drawing power to their membranes. Now the reason why when one eie is mooued to the side the other also necessarily followeth, is, because these nerues are continued one with another in their originall.

Their vse.

Why both eies moue together.

CHAP. XVIII. *Of the third and fourth coniugations of the Nerues of the Braine.*

The 3. Coniugation.

THE third coniugation [Tab. 19, fig. 1 and 2 [L]. Ta. 15, fig. 20 [M]] is sent vnto the Muscles of the face & is commonly called the smaller *roote* of the third paire, but it deserueth, we think, to be a particular coniugation, because it is not ioyned with the following paire [Tab. 15. fig. 20 [I]. Tab 19. fig. 1 and 2. [L] with [M]] neyther in his beginning nor in his progresse.

His Original.

It ariseth from the lower and backer part of the marrow of the Braine. It is very smal and perforateth the *dura Meninx* at the side of the basis of the Braine where it is fastned to the second coniugation [Tab. 19, fig. 1. [R]] and so with it yssueth into the orbe of the eye by a hole common to them both. [Tab. 3. fig. 8, [o]] Then it is diuided into four branches: the first [Tab. 19. fig. 2 [N]] ascendeth vpwarde by the fat of the eye and yssueth at a hole of the forehead bone proper vnto it [Tab. 3. fig. 8 [A]] and so passeth into the skinne of the Forehead to which it giueth motion, as also to the vpper eye-brow.

Issue. 4. Branches.

The second descendeth [Tab. 19. fig. 2. O] and passeth through a hole of his owne, bored in the fourth bone of the vpper Iaw [Table. 3. fig. 8. [B]] and so is dispersed into the Muscles of the vpper lip, into those that moue the wing of the Nose outward, into the tip it selfe and some of the gummes.

The third branch [Tabl. 19. fig. 2. [P]] passeth thorough the second hole of the vpper iaw [Tab. 3. fig. 8 C] and attaineth into the Cauity of the Nosethrilles and is spent into their coate, [Tab. 19. figu. 2. the lower P] and affoordeth a small surcle to the membranous Muscle vvhich contracteth the wing of the nose.

The fourth branch [Table. 19. fig. 2. [Q]] being led thorough the Fissure which is betwixt the bone of the vpper iawe and the Wedge-bone [Tab. 3. fig. 8 [D]] is spent into the inner part of the temporall muscles.

The fourth Coniugation.

The Fourth Coniugation are the Nerues of Tasting, [Tab. 19. fig. 1. and 2. [M]. Tab. 15. fig. 20. I] it beareth on the former in his progresse but not in his originall.

The reason of his Originall.

It proceedeth not out of the backe parts of the brain because they are hard; not out of the sides because their waye would not haue been safe; but out of the basis yea the very Marrow of the Braine [Tab. 25. fig. 1. Char. 3] aswell for security as because of the Situation of the toong.

Where it yssueth.

It yssueth at the sixt hole of the wedg-bone [Tab. 3. fig. 9. [Q]] and presently sendeth a Surcle out of it like the crumpled Tendrill of a Vine, in which the Animall spirit maketh some stay. Afterwards, it is by two branches vnited to the Nerue of Hearing, [Table. 19. fig. 1, 2. [b c]] and so is disseminated into the muscles of the face the Temporall, the grinding Muscles of the Cheekes and to the Skinne of the face.

It hath three branches.

A second branch it also parteth with [Tab. 19. fig: 2 S] which affoordeth surcles to that part of the Gummes wherein the grinding Teeth are fastened, yea vnto the teeth themselues.

TABVLA. XIX.

FIG. I.

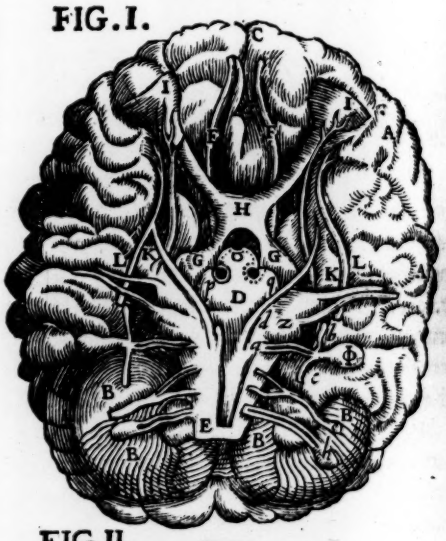

FIG. II.

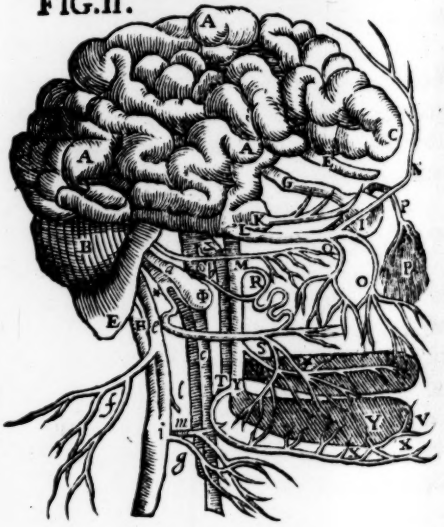


A third branch also sprowteth out of his back-part, [Table 19, fig.2.[r]] which is inserted into the muscle that lurketh within the mouth, and passeth through the inner hole [tab.11. lib.8.fig.2.[r]] of the lower Iaw, and there offereth surcles to the Rootes of the lower teeth on the same side, [Tab.19, fig.2.[xx]] and by their helpe the teeth haue sense, whereas the other bones haue none. How the teeth haue sense.

Finally, the Trunke it selfe [Table 19, fig.2.[y]] passing through the muscles lurking in the mouth together with the Trunke of the other side attaine to the side of the tongue and is consumed into his coate to make it a conuenient Organ of Gustation.

CHAP. XIX. *Of the Nerue of hearing, or of the fift Coniugation of the Braine.*

THE fift Coniugation [Tab.20, fig.1, and 2,[a] Tab. 15, fig.20.[x]] ariseth out of the Marrow of the Braine lengthened, where it ioyneth with the *Cerebellum*. [Table 25, figure 1,[i]] There his originall seemeth to be out of two Surcles or Nerues, the one softer the other harder, which together perforate the membrane and passe to the stony bone. The fift Coniugation. His 2. surcles.

This Nerue passeth through a notable writhen hole thrilled in the stony-bone, which they call the fift hole of the Temple bone, where it meeteth with that cauity which is compared to a Conniborough and prepared for the Organ of hearing. Afterward the harder part falleth into the cauity called *Tympanum* or the Drum. His out-gate.

The softer part [Table 20, fig.2,[a]] which is indeed *Neruus auditorus* the sinew of hearing, accompanieth the former, and when it attaineth to the extremity of the aboue named cauity it is dilated like a membrane [Table 20, fig.1,2.[Φ]] and becommeth the speciall Instrument of hearing, and in that place remaineth haply after the same manner that wee saide before the Organ of Smelling was extended. The true Organ of hearing.

CHAP. XX. *Of the sixt, seauenth, and eight Coniugations of the Sinewes.*

THE sixt Coniugation [Tab.21, fig.1, and 2,[c] Tab.15, fig.20.[y]] taketh his beginning of a few fibres a little below the originall of the Nerue of *hearing*. These Nerues being instantly vnited doe make one notable Nerue as some haue thought, but indeed they are neuer so vnited but that they remaine two Nerues contained or held together in one membrane, and passe out at one hole, [Tab.4, fig.10.[b]] which is counted the 2. hole of the *occipitium* or Nowle-bone. The one of those is the forwarder & the lesser: the other the backwarder & the greter. The lesser runneth directly to the muscles of the tongue, and for the most part is spent in the mouth; the greater as soone as it is issued out of the Scul sendeth a branch backward [Tab.21, fig.2, [f]] which is diuersly distributed into the *Mũcks-hood* muscle of the shoulder blade. The trũk it selfe descending is tyed to the seauenth Coniugation, [Tab.21, fig.2.[x]] and at the sides of the throtle is increased with a branch from that seauenth Coniugation, [Table. 21, fig.2,[i]] with which notwithstanding it is not mingled but onely colligated or tyed: after it sendeth surcles to the muscles of the *Layrinx* or throtle, [Tab.21, fig.2.[g]] as also some other smaller to the muscles of the Chops, thence it descendeth to the Chest, where we will leaue it til another time. That the fixt Coniugation is not one but two Nerues. Where it issueth. The course of it.

The seauenth Coniugation [Ta.21, fig.1,[h] fig.2,[x]] moues the tongue, and is the hardest of all the sinewes proceeding out of the Scull; for it ariseth iust at the place where the marrow of the braine falleth out of the Scul. [Tab.21, fig.1,2,[x]] It ariseth of many Roots somewhat distant each from other, which ioyning together into one do passe out of the Scull at an oblique hole bored in the bone of the *Occipitium*, and for more security is ioyned by strong membranes with the sixt Coniugation, yet not mingled therewith. For this seauenth paire keepeth his owne body and so runneth downward to the roote of the tongue, where the most part of it [Ta.21, fig. 2,[z]] is loosened into many fibres which giue motion therto. Other parts of it are deriued to the muscles of the bone *Hyois* and the Throtle to giue them motion; some surcles also it sendeth [Ta.21, fig 2,[l]] to those muscles that arise from the appendix called Stylo-ides. The seauenth Coniugation. His originall and course.

The eight Coniugation [Tab.21, fig.1,2,[d] Table.15, fig.20,[z]] proceedeth out of the marrow of the braine aboue the Auditory Nerue betwixt the second and the third Coniugations. The eight Coniugation.

It

It perforateth betwixt thoſe 2. paires the thicke Meninx and attayneth into the orbe of the eye through the hole that belongeth to the ſecond coniugation, and is almoſt wholly ſpent into that muſcle of the eye which draweth it vnto the vtter corner.

CHAP. XXI. *Of the Nerues proceeding from the ſpinal marrow properly ſo called.*

HAuing acquainted you with thoſe coniugations of ſinewes which belong vnto any part of the brain or his productions contained within the Skull, it remayneth nowe to giue you a ſhort viewe of thoſe nerues which are deriued out of the ſpinall marrow contayned in the rack-bones of the Chine. Theſe therefore are accounted to be 30. paire, all proceeding out of diſtinct and ſeuerall parts; that is to ſay out of the racks of the neck, the cheſt, the loines & the holy-bone.

Seauen or 8. paires of the Necke.

The Coniugations of the Neck ſome account ſeauen, others eight, diſperſed into the outſide of the whole head and the muſcles thereof.

The firſt Coniugation yſſueth betweene the *Occipitium* or Nowle bone & the firſt rack-bone, and is diuided into two little branches, a forward and leſſer, [Tab.22,[n]] and a backward. [Tab.23,[r]]

The ſecond Coniugation of the Necke hath two originals, a forward [Tab.22,[x]] and a backward which is the larger, [Table 23,[t]] which is diuided into two branches, a thicker [Tab.23,[x]] and a thinner. [Tab.23, aboue [x]]

The 3. paire [Ta.22, charracter[3]] breaketh out of the common hole betweene the ſecond and the third ſpondels or rackes and is diuided into two branches, one forward [Tab.22, [r]] which is ſubdiuided into foure Surcles. The firſt at Tab. 22,[o].] The ſecond at Ta. 22, and 23,[x].] The third at Tabble 22,[s] and Table 23,[x l].] The fourth at Tab.22, and 23,[r].] Another backward, [Tab.22, and 23,[o]] diſſeminated into the muſcles which are common to the head and the necke.

The fourth Coniugation [Tab.21, Char.[4]] falleth out of the common hole of the third and fourth *vertebræ*, and is diuided into two branches, the firſt forward and greater, [Tab. 22, and 23,[x]] which is diuided into three Surcles, the firſt at [tab.22,[y].] the ſecond at [tab. 22,[z].] the third at tab.22,[b].] The ſecond branch is the leſſer and more backward, [tab.22, and 23,[y]] and is ſpent in the muſcles of the Necke and the membranous muſcles of the Cheekes.

The fift Coniugation [tab.22, char.[5]] falleth out vnder the fourth rack-bone, and is diuided into two branches, one forward and another backward; the forward [tab.22, & 23,[f]] hath three Surcles, the firſt at tab.22,[a d]] the ſecond [tab.22,[c]] the third [table 22, & 23,[f]] The backward branch [tab.23,[c]] is diſtributed as is the backward branch of the fourth paire.

The ſixt Coniugation [table 22, char.[6]] falleth out vnder the firſt racke, and is likewiſe diuided into a fore and a hinder branch: the fore branch at [table 22,[l]] the hinder branch at [table 23,[k].]

The ſeauenth Coniugation [table 22, char.[7]] yſſueth vnder the ſixt racke bone of the Necke, and is ioyned with the ſixt paire of the Necke and the firſt of the Cheſt [tab.22,[f].] for more ſecurity; and the greateſt part of it paſſeth into the arme, which ſometime ſendeth a branch to accompliſh the Nerue of the Midriffe. The backer branch [table 23,[f]] is the leſſe, and is beſtowed vpon the muſcles lying vpon the necke and vpon the ſquare muſcle of the Cheeke, which firſt ſuffereth conuulſion in the diſeaſe called *Spaſmus Cynicus*, or the Dog laughter.

And thus much of the Nerues proceeding from the ſpinall marrow contained within the *vertebræ* or ſpondels of the necke, which we ſayde were ſeauen Coniugaions. It followeth now that we ſhould intreate of the nerues proceeding from the marrow of the rack bones of the Thorax or Cheſt. Of theſe there are as ſome thinke but eleauen Coniugations others reſolue of twelue, all which after their outlet are diuided into two branches, one greater, the other leſſer; one paſsing forward, another reflected backward.

Twelue paire of the Cheſt.

The firſt Coniugation [table 22, char.[8]] is ſnewed betwixt the ſeauenth bone of the Neck and the firſt of the Cheſt. It hath two branches, the firſt greater ſendeth certaine propagations to the ſhoulder blade [table 23,[aa]] to the firſt rib. [table 22,[y]] The ſecond leſſer [table 23,[u]] is diſſeminated into the adioyning muſcles.

The ſecond Coniugation [table 23, char.[9]] yſſueth betwixt the firſt and ſecond bone of the Cheſt; then it diſtributeth a branch backward, [table 23, [e]] and after is ioyned with a branch

branch of the former Coniugation, [tab. 23, ^] & so passeth into the arme; that which remaineth of this Coniugation followeth the course of the first ribbe, and maketh an intercostall Nerue.

The 3. Coniugation as also all the other nine [table 22, from char. [10], to [20]] of the Chest are distributed after the same manner. For after they fall out of the sides of the *vertebræ* they are diuided into two branches, one forward and another backward; the forward branches are called Intercostales, that is, *betwixt the ribs*, [table 22, nn] for from them many branches are disseminated into the Intercostall muscles, [table 22, θθθ and the charracters of the left side] into the muscles lying vpon the Chest, [table 22, θθ ιι κκ] as the great and lesser *Saw*, the pectorall and the broad Muscle; [table 22, μμ] and are strangely reflected to the vessels thereabout. The backward branches leane backward to the spines or sharpe points of the *vertebræ*, and are deriued into the muscles which moue the backe of the Chest, and into the skinne of the backe; but their distribution is not in all men alike. The third and all the rest.

Finally, the two last coniugations of the twelue do send Surcles [tab. 22. at the sides of the 18. and 19. Characters] to the head of the sixt muscle of the thigh.

From the spinall marrow contained in the racks of the loynes doe arise fiue coniugations greater then the former, deuided likewise after their out-gate into a forward & a backward branch, and from their backward branches [table 23, char. [51] and [53]] send surcles into the muscles which grow to the *vertebræ* of the Loynes. The nerues of the Loynes fiue paire.

The first Coniugation [table 22, char. [20]] as also all the rest yssue out of the holes of the *vertebræ* vnder the *Peritonæum*, and is diuided into two branches, a greater and *anterior* partly ascending to the *Diaphragma*, partly to the muscles of the *Abdomen* or paunch, and a lesser and *posterior* which is reflected into the muscles which leane vpon the *vertebræ* of the Loynes.

The second Coniugation [table 22, char. [21]] runneth vnder the sixt muscle of the thighe and riseth to the top of the haunch bone, but the forward branch is distributed to the sixth internall Iliack, and the first bender of the legge. It sendeth also a small long nerue [table 21, char. [49]] accompaning the spermaticall vessels of the same side euen vnto the Testicle.

The third coniugation [Table 22. Char. [22]] yssueth also vnder the Lumball muscle; the fore-branch passeth neare the haunch-bone & is deuided into two propagations, one going to the knee the other accompanying the veine called *Saphena*; but the back braunch is reflected and disseminated into the muscles, lying vpon the loynes and into the skin. So likewise from all the fore-branches of the three first coniugations certaine shootes [Table 22. & the sides of the 20. 21. 22. Characters] do attaine to the costall nerue, and are loyned therewith.

The fourth Coniugation [Table 22. Char. 23.] which is the biggest of all the coniugations of the loynes accompanieth the veine and arterie to the groine, and distributeth certaine surcles to the forward muscles of the thigh and the leg.

The fift coniugation [table 22. Char. 24.] is parted in twaine as are the former. The fore-branch and the greater passeth through a hole betwixt the *Coxa*, the share-bone and the haunch-bone and sendeth diuers shootes to the muscles of the thigh, the yarde, the neck of the wombe also and the bladder; but the backe-braunch is reflected to the muscles, they leane vpon the *vertebræ* of the loynes and into the skin there abouts. Furthermore, these coniugations are tyed one vnto another, the first to the second, the second to the third, the third with the fourth, and the fourth with the fift, as is shewed in the first figure of the 22. Table.

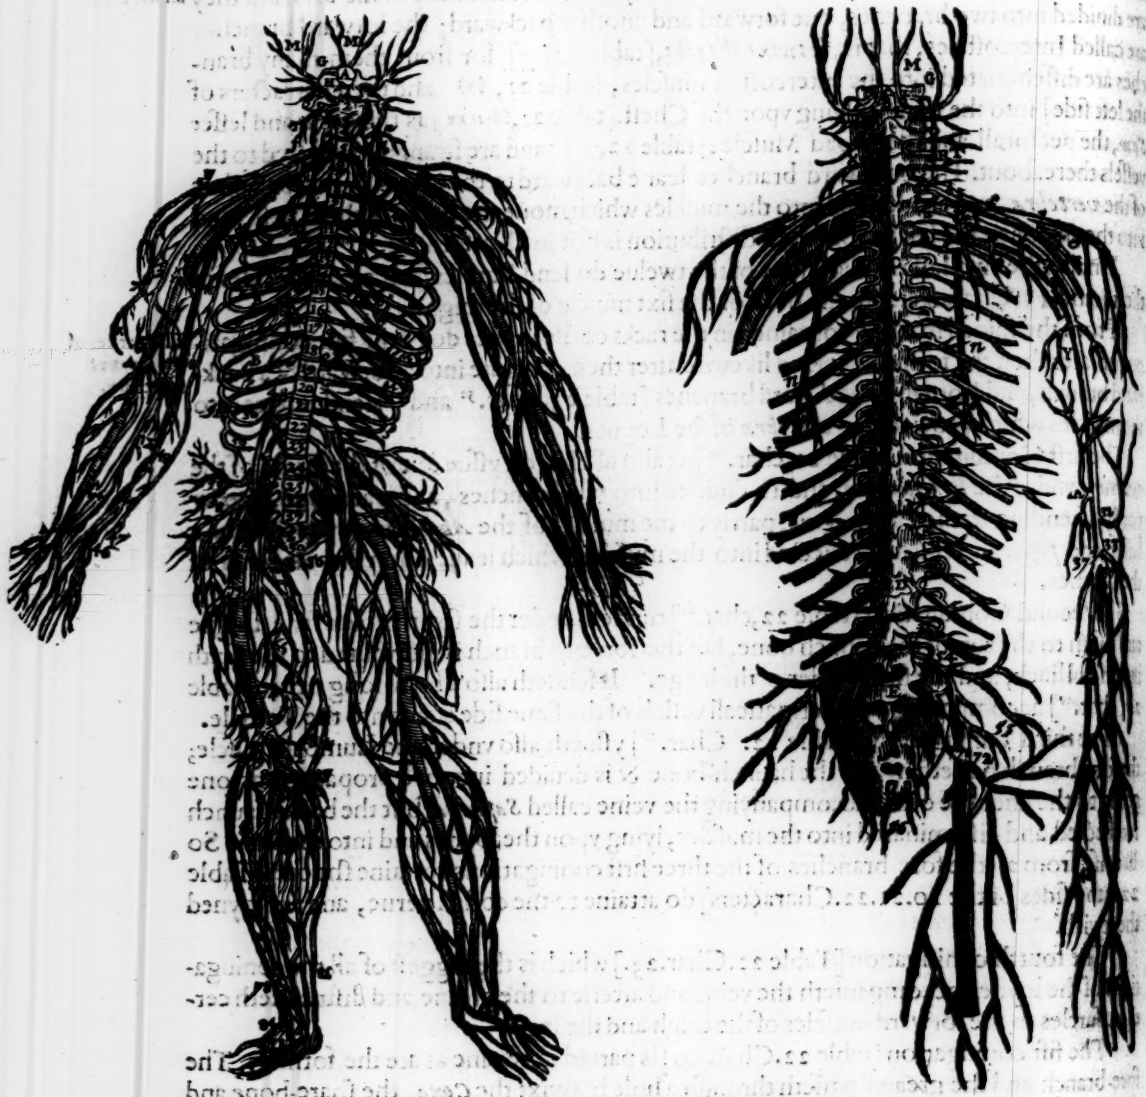
To conclude, out of the marrow conteyned in the *vertebræ* of the *Os sacrum* or holy-bone doe proceed sixe coniugations. The nerues of the Os sacrum.

The first [Table 22. char. 25.] yssueth betwixt the last of the loyne and the first racke of the holy-bone, and is deuided into a fore-branch and a hind-branch; the fore-branch sendeth a surcle [table 22. charact. 43] into the inside of the haunch-bone, from which certaine shoots are offered to the muscles of the *Abdomen*, and the seuenth muscle of the thigh. The back-braunch passeth in a like course as doe the backe branches of the other coniugations aforesaid beside into the muscles [table 23. charact. 54.] produced from the haunch-bone, specially into the first mouing the thigh, from whence it is consumed into the skin.

The fiue other coniugations [table 22. from the 26. to the 30. chara.] are produced after another manner for before they yssue they are double on either side; one proceeding forward and another backward. Of the fore-branches the three vppermost runne to the leg, the The other fiue.

Table 22. and Table 23. Because the same Characters belong to them both, we haue set them together.
Table 22. sheweth the Racks of the spine and the nerues yssuing there from on the foreside.
Table 23. sheweth the same Racks and Nerues on the backside.

TABVLA XXII. & XXIII.



A 1,2, The spinall marrow as it goeth into the rack-bones. BC 2, The seauen *vertebræ* or racke bones of the neck. Character from 1,2, to 50. in the 15. table do shew the racks of the whole spine. CD 2, amongst these the twelue racks of the Chest. DE 2, The fiue Racks of the Loynes. E 2. The holy bone. F 2, the hinder braunch of the first coniugation of sinewes. G 1,2, the distribution of the same branch into the muscles of the head. H 1, the forward branch of the first coniugation. I 2, a small branch of the hinder propagation of the second paire which is distributed vpward. K, a thicker braunch of the same nerue. L 2, the coition or coniunction of a branch of the third paire, with the branch of the second paire marked with K. MM 1,2, the second paire distributed vnto the skin of the head as far as to the necke. N 1, the *anterior* branch of the second paire. Character 3 in the first Table sheweth the third coniugation and the third rack-bone. O 1,2, the hinder branch of the third paire reflected first backeward, then forward vnto the muscles: & such a reflection there is in all the nerues vnto char. 24. P 1, the *anterior* braunch of the third paire parted into foure. Q 1, the first going vnto the muscles. R 1,2, the second ioyning with the fourth paire. S 1, the third commixed with the branch K. T 1,2. the fourth branch going to the muscles of that place. Character 4, in 1, the fourth coniugation of the fourth rackbone. V 1,2, the *posterior* branch of the 4. paire. X 1,2, the *anterior* braunch of the 4. paire parted into three. Y 1, the first admitting the branch R. *a* 1, the 2 going to the muscles. *b* 1, the 3 reaching to a part of the fift payre marked with. Char. 5 in 1, the 5 paire. *c* 2, the *posterior* branch of the 5. payre. *d* 1,2, the *anterior* brach of the 5. paire. *e* 1, this portio maketh the nerue of the midriffe. *f* 1,2, a brauch of the nerue *d* creeping along the top of the shoulder, vnder which are certain surcles attaining to the shoulder blade. *g* 1,2, a surcle of the nerue *f* deriued to the skin on the top of the shoulder. *h* 1,2, a surcle of the nerue *f* going to the second muscle of the arme. *i* 1,2, another branch inserted into the same muscle and the skin. Char. 6, in 1, the sixt paire. *k* 2, the *posterior* braunch of the same sixt coniugation. *l* 1, the *anterior* braunch of the same coniugation. *m* 1, a surcle of the same nerue appointed to make vp the sinew

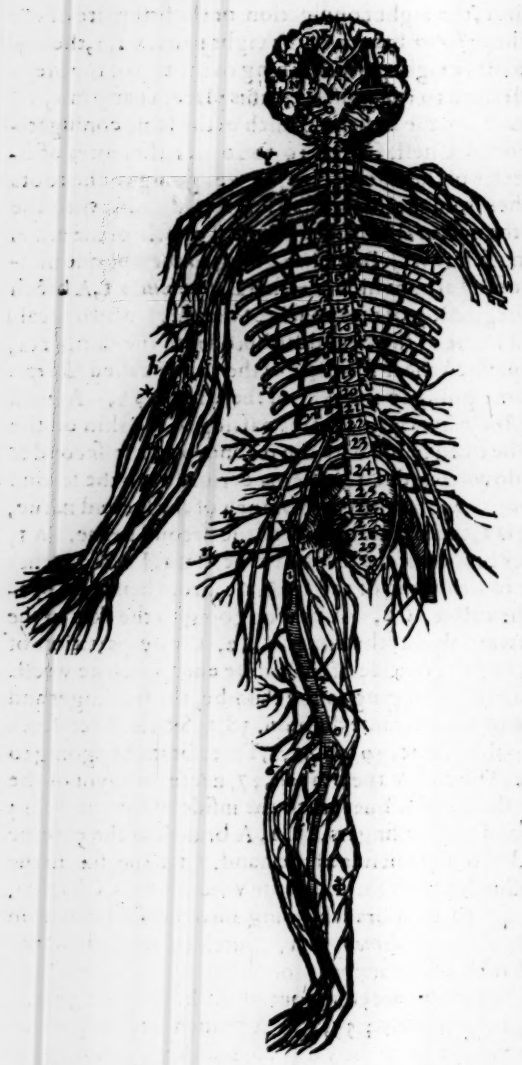
Sinew of the midriffe. *n* 1,2, the nerue of the midriffe made of three ſurcles, *b*,*b*, and *m*. *oo* 1,2, the inſertion of this nerue into the midriffe. *p* 2, A branch of the ſixt coniugation running to the cauity of the ſhoulder blade. *q* 1,2, the coniunction or implication of the branch *l* with the branches neighbouring about it. Char 7 in 1, the ſeauenth coniugation of ſinewes. *r* 2, the *poſterior* branch of the ſeauenth paire. *ſ* 1, the congreſſe or meeting of the ſeauenth coniugation with the branches that are neere it. *tt* 2, Surcles of this nerue deriued to the muſcles of the ſhoulder blade and the arme. char 8. in 1, the eight coniugation or the firſt paire of the Cheſt running aboue the firſt rack-bone of the Cheſt. *u* 2, the *poſterior* branch of the eight paire. *x* 1,2, the coition or coniunction of the 8. paire with the 7. *y* 1, A brãch of the eight paire reaching to the top of the breſt. *uu* 2, Surcles proceeding from the eight coniugation and deriued to the muſcles in this place. char 9 in 1, the ninth paire of nerues. *β* 2, the *poſterior* branch of the ninth paire. *δ* 1, the *anterior* branch of the ſame coniugation. *ζ*, 1 Surcles from this branch to the diſtances or ſpaces of the Cheſt. Chara. 10, to 20, in 1, the paires of ſinewes deriued to the diſtances betwixt the ribs. *mm* 1, Surcles of the intercoſtall ſinewes going to the roots of the ribs and increaſing the *coſtall* nerues. *θθθ* 1, Branches from the intercoſtall ſinewes deriued vnto the muſcles which lye vpon the Cheſt. *ιι*, 1 Branches going to the pectorall muſcle or the firſt muſcle of the arme. *κκ* 1, Other branches going to the lower ſide of the ſame muſcle. *λλ* 1, Branches going to the oblique muſcles of the *Abdomen*. *μμ* 1, Others deriued to that muſcle of the arme which is called *Latiſſimus*. *ν* 1, A brãch paſsing vnto the Pap. *οο* 1, Branches from 18, & 19, to the beginning of that muſcle of the thigh which is called *Lumbalis* or the ſixt muſcle of the Thigh. *ππ* 1, the firſt nerue of the arme diſtributed into the skin. *ρ* 1,2, the ſecond nerue of the arme. *σσ*, 1, From this doe nerues paſſe to the firſt muſcle of the cubite called *Biceps*. *τ* 1,2, The third nerue of the arme. *υ* 1,2, A branch of the ſame going to the skin of the arme. *φ* 1, A ſmall branch deriued to the ſecond muſcle of the cubite called *Brachiæus*. *χ* 1, Others paſsing to the skin on the foreſide of the arme. *ψ* 1, the congreſſe or coniunction of the third nerue with the ſecond. *ω* 1, the ſecond & the third nerues after their coniunction doe heere creepe downeward. *Γ* 1, A Nerue deriued vnto the ſecond muſcle of the *Radius* which muſcle is called *Supinator longior*, *ΔΔ* 1, the vpper branch of the ſecond nerue, running to the wreſt and to the firſt ioynt of the thumbe. *Θ* 1, the middle branch of the ſecond nerue, *Λ* 1, the progreſſe of the ſame euen vnto the hand. *Ξ* 1, the lower branch of the ſecond nerue. *ΠΣ* 1, Two branches of the ſame nerue going to the inſide of the hand. *Φ* 1,2, the fourth nerue of the arme. *Υ* 2, From hence do proceede nerues to the muſcles which extend or ſtretch out the cubite. *Ω* 2, A branch going to the skin of the arme on the backſide. 32, 2 Branches deriued to the outward skin of the arme. 34, 2, the by-partition of the fourth nerue at the cubite. 33, 2, A branch creeping along the outſide of the cubite euen vnto the wreſt. 35, 2, The vpper branch of the foreſaide diuiſion. 36, 2, Surcles belonging to the thumbe, the forefinger and the middle finger on their outſides. 37, 2, the lower branch of the foreſaide diuiſion. 38, 2, Surcles heerefrom to the muſcles ariſing out of the externall bunch of the ſhoulder bone. 39, 40, 41, 2, Three branches going to the muſcles which ſpring from the bone called *Vlna*. 42, 2, The end of the branch, 37, neere the ioynt of the wreſt. * 1, 2, The fift nerue of the arme. 43, 1, Surcles of the third and fift nerues to the inſide of the cubite, 44 1, A branch of the third nerue going to the palme of the hand and the fingers. 45, 1, A branch of the 5, nerue to the inſide of the hand. 46, 1, A Surcle of the branch 45, led to the outſide of the hand. 8, 1, 2, the ſixt nerue of the arme. 47, 1, the end thereof next the ioynt. 48, 48, 1, Surcles from the ſixt nerue vnto the skin. Char. 20, to 24, 1, Nerues proceeding out of the racks of the loynes. 49, 49, 1, A branch going into the Teſticles from the 20 paire. 50, 50, 1, The nerues belonging to the muſcles of the *Abdomen*. 51, 1, Surcles from theſe to the broad muſcle of the arme called *Latiſſimus*. 52, 52, 2, The backward branches proceeding out of the racks of the Loynes. Char 25, to 30, The coniugations or paires of ſinewes proceeding out of the holy-bone. 53, 1, A branch of the 25 paire going to the inſide of the *coxendix* or hip-bone. 54, 55, 2, A branch attaining to the outſide of the *coxendix*. * 2, Hence proceedeth a nerue communicated to the yard. 56, 2, the end of the ſpinal marrow. 57, 1, The firſt nerue of the Leg. 58, 1, Brãches here from to the skin. 59, 1, Other brãches herefrom to the muſcles. 60, 1, The 2. nerue of the Leg. 61, 61, 1 Brãches herefrom to the skin. 62, 1, A brãch deſcẽding to the top of the foot. 63, 1. Branches from 61, compaſsing the knee. 64, 1, A branch of the 2. nerue going to the muſcles. 65, 1 A brãch here-from going to the fift muſcle of the thigh cald *Triceps* 66, 1, the nerue of the Leg. 67, 1, A ſurcle creeping to the hole of the ſhare-bone. 68, 1 A branch allowed to the skin on the inſide of the thigh. 69, 1. A portion of the third nerue going to the muſcles. 70, 1, A portiõ hereof communicated to the 2. muſcle which bendeth the leg or *Tibia*. 71, 1, 2, The fourth nerue of the leg 72, 1, 2, A branch heereof communicated to the skin of the thigh in the backpart. 73, 1, Another to the muſcles which ariſe from the *Coxendix*. 74, 1. A branch allowed to the fourth muſcle of the *Tibia* or leg and to the skin. 75, 1, Surcles from the fourth to the heads of the muſcles of the foote. 76, 1, The diuiſion of the fourth nerue in the Ham into two Trunkes. 77, 1, the outward trunke. 78, 78, 1, A branch heere from to the skin of the leg or *Tibia* on the outſide as farre as to the little toe. 79, 1, Another branch inſerted into the muſcles. 80, 1, A branch diſperſed into the skin of the foreſide of the leg from the branch. 79 81, 1, A part of the branch. 79, going to the muſcles of the foote. 82, 1, the inner trunke of the fourth Nerue. 83, 83, 1. A branch creeping along the inſide of the legge vnder the skin. 84, 1. A branch of the Trunke, 82, diſpoſed vnder the skin to the back ſide of the Calfe of the legge. 85. 85. 1, A branch of the trunke, 8 2, creeping along the foreſide of the legge to the vpper part of the foote. 86, 1, A branch of the trunke 82, paſsing along the backſide of the legge and diſtributed to the muſcles. 87, 1, The remainder of the inner trunke allowed to the Toes.

The two lowermoſt are diuerſly diſtributed into the muſcles of the Fundament & the Bladder and parts thereabouts. But the back-branches [table 23. char. 54. and 55] are diſtributed into the muſcles on the backſide of the hanch and holy bones, and into the skin of the buttocks.

Finally,

Table 24. sheweth the Braine together with the After-braine, the spinall marrowe and the nerues of the whole body.

TABVLA. XXIIII.



A, that part of the brain that is next the nosethrils.
B, that part which is at the side of the ventricles.
C, the backpart of the braine.
D, the *Cerebellum* or After-braine.
E, the Mamillary processe on the right side.
F, the originall of the opticke nerue.
G, their coniunctions.
H, The coate into which the optick nerue is extended.
I, the second paire of the sinewes of the braine.
K, the lesser roote of the third coniugation.
L, the thick roote of the same coniugation according to the common opinion.
M, the fourth coniugation of sinewes.
N, the lesser roote of the fift paire.
O, the bigger roote of the same paire.
P, The small membrane of the eare which they call the *Tympanie*.
Q the lower branch of the bigger roote of the fift coniugation.
S, the sixt paire of sinewes.
T, the seauenth paire.
V, the beginning of the spinall marrow out of the middle of the Basis of the braine.
X, the right sinewe of the midrisse cut off.
Y, a branch from the fist paire creeping to the top of the shoulder.
Z, the first nerue of the arme from whence there goeth a branch to the skin.
A, the second nerue of the arme, and a branch therefrom into the first muscle of the Cubite.
B, the third nerue of the arme and a branch going to the skin on the outside.
C, a branch from the third nerue to the second muscle of the Cubite.
D, the congresse or meeting of the second nerue with the third.
E, a small branch from the third nerue to the second muscle of the *Radius*.
F, the distribution of the second nerue into two branches
* The lesser branch of this diuision lengthened out to the skin as far as the thumbe.
a, the place of the spinall marrow where it yssueth out of the braine.

1,2,3, &c. Thirty paire of nerues arising from the spinall marrow are here noted by their Characters, that is to say, seauen of the necke, twelue of the Cheft, fiue of the loynes, and sixe of the holy bone. *b*, the thicker branch of the second nerue deuided into two parts. *c*, Braunches of the third nerue sprinkled here and there. *d*, Nerues from the third paire to the thumb, the forefinger and the middle finger. *ee*, the 4. nerue of the arme. *f*, the passage hereof through the inside of the shoulder. *g*, a tripartition of this braunch where it toucheth the Cubite. *b h*, a branch distributed from the fourth nerue to the outward skinne of the Cubite. *i*, the vpper branch of the deuision of the fourth nerue, *kk* a branch of *i* reaching to the outside of the hand. *ll*, the lower branch of the diuision of the 4. nerue passing through the backeside of the Cubite. *m*, the fift nerue of the arme. *n*, branches of this nerue dispersed here and there. *o o*, a branch of the 5. nerue reaching to the inside of the hand and the fingers. *p*, a surcle of the braunch *o* deriued to the outside of the hand and the fingers. *qq*, the 6. nerue of the arme and the course thereof vnder the skin. *rr*, the Intercostall nerues, there cut off where they are together with the ribs reflected forward. *ss*, branches on each side running backward. *t t*, nerues attaining vnto the cheft. *uu*, the commixtion of the nerues *rr* with the descending branch of the sixt coniugation of the braine. *xx*, nerues from the loynes led vnto this place. *y*, a branch going to the testicle here cut off. *z*, a nerue reaching to the first muscle of the thigh. *e*, the first nerue of the leg. *αβ*, a surcle of the former nerue deriued to the skin at *α* and inserted into the muscles at *β*. *γ*, the 2. nerue of the leg. *δδδ*, a nerue from the former, allowed vnto the skin as low as to the foot, & passing along the inside of the leg. *ε*, a branch of the 2. nerue running vnto the muscles. *ζ*, the third nerue of the leg. *η*, a surcle thereof vnto the skin. *θ*, another surcle vnto the muscles. *ι ι*, the 4. nerue of the leg. *κκ*, the *anterior* propagations of the nerues proceeding from the holy-bone. *λ*, the end of the spinall marrow. *μ*, a branch from the 4. nerue inserted into the muscles arising from the *Coxendix* or hip bone. *ν*, another branch going to the skin of the thigh on the backside. *ξ*, a propagation deriued to the 4. muscle of the leg & to the skin of the knee. *oo*, nerues attaining to the heads of the muscles of the foote. *πρ*, the deuision of the 4. crurall nerue into two trunks. *σ*, a branch from the trunk *π* dispersed into the outward skin of the leg. *τ*, a surcle of the trunk *π* deriued to the muscles. *υ*, another surcle to the skin of the leg on the foreside. *φφ*, a branch of the trunk *ρ* to the skin of the inside of the leg & of the foot. *χ*, a surcle of the trũk *ρ* to the hindmost skin of the leg. *ψ*, a brãch of the whole trunk *ρ* led along to the forward part of the leg & the foot. *ω*, the deſcẽt of the trũk *ρ* into the foot.

Final'y, the end of the spinall marrow [table 22. and 23. char. 56.] proceeding from the holy-bone sendeth one propagation on either side, which is sometimes diuersly diuaricated and disseminated into the fourth muscle of the thigh, and the skinne betwixt the buttocks and the fundament. Notwithstanding in Dogs and Apes there are three coniugations proceeding out of the Coccyx or rump-bone.

Wherefore to summe vp all, we must remember that the spinall marrow hath 30. paire or coniugations of sinewes; seauen belonging to the marrow of the necke, twelue to the marrow of the backe, fiue to the marrow of the loynes and sixe to the marrow of the holy-bone: all which it is very necessary a Physition and Surgion should know, that hee may be able to apply Oyntments, Cataplasmes and such like to the proper parts of the spine, when the nowle of the head, the face, the necke, the hands, the parts of the Chest, the muscles of the *Abdomen*, the wombe, the bladder, the fundament, the yard or the legges are depriued of Sence or Motion or both together. The vse of this chapter.

CHAP. XXII. *Varolius his manner of dissecting the Head.*

THere is in the body of man so great variety of all manner of parts, that it is impossible to follow the trace of Nature by humane diligence so neerly that a man shall not sometimes wander out of his way or be at losse. It is therefore no wonder if the ancient and first Anatomists (men questionlesse very oculate and sharp sighted) did not yet attaine to the exquisite knowledge of all particulars, but left many thinges to bee found out and perfected by their Successours. Nay we assure our selues that no processe of time, diligence of inquisition or helps of other mens labours shall euer be able to bring Anatomy to such perfection, but that there will be place left for them that come after to finde out something neuer before discouered; so like is this little world of mans body to the great globe of the Vniuerse, wherein euery day new Countries and Nations, yea populous and rich states and Common-wealthes are by Trauellers found out. An instance hereof in the Art we haue in hand is *Constantinus, Varolius*, who in the yeare 1570. inuented a new manner of dissection of the braine, which how it is accõplished as we haue partly learned by his Epistles written *An.* 1573. partly by our own dissections saith *Bauhine*, for these 24. yeares together we will here relate, because it doth better exhibite the true originall of the spinall marrow and the nerues proceeding there from, as also the structure of the ventricles for our better satisfaction in the causes of the deseases of the head and the explayning of some passages in *Hippocrates* and *Galen*. *Varolius* his inuention.

The difference betwixt these two Administrations is, that in the former, the vpper parts of the skull and the Meninges of the braine being remoued, the contayned parts are layde open to the view. But in this which is full of labour and difficulty, the bones of the head are on euery side remoued; and the parts contained within the skull yet couered with both the membranes hauing the eyes, the coniugations of the sinewes and the spinall marrow ioyned thereto; are at one view represented and the section begun at the Basis of the brain. But for this Administration the head must be greene and not waterish, otherwise we shall loose our labour: you must therefore take the head of a man newly cutte off, or for want thereof a Calues head will serue the turne, because all the particulars may bee therein discerned. How admnistred.

Of the Spinall Marrow.

First of all wee must begin at the *Spinall Marrow* which they say ariseth from the lower Basis of the braine at the great hole of the *occipitium* or nowle bone. [table 25. fig. 1. from [p] to [o]] This is established within the skul in his proper seat and is compassed or inuested with the membranes: wherefore after the thicke Meninx is remoued, the other called *pia mater* is also to be taken away, which is transparant and strong, & by whose mediation the forepart of the marrow is tyed to the braine and the hind part to the After-brain. It also detayneth or establisheth the spinall marrow that it be not reflected backward, which haply is the cause why Anatomists haue not knowne his true originall; for if you take it vp with a hooke and lightly remoone it with a knife from the partes vnder it, and bend the spinall marrow somewhat forward [Table 25. figure 2. [a b]] then will his originall shew it selfe to be not in the *occipitium* or where it was first tyed to that thin membrane, but ascending somewhat vpward and in the forepart of the braine. The admini-stratiõ of the spinall marrow.

This Marrow therefore consisteth of foure roots, whereof the two greater [Tab. 25, fig. 2, [b c] sheweth the trunke reflected, Char. 4. and 1. shew the trunke in his owne seate] The 4 roores thereof.

do yſſue out of two parts of the Braine in that place wherein the Ventricles are reflected [Tab. 25. fig. 2. f g] from the forward prominence or ſwelling of the brain vnto the middle, & whereabout the Opticke Nerue [Tab. 25. fig. 2. c d] paſſeth without the ventricle.

Where ioined

The other two Roots are two ſhort trunkes of the *Cerebellum* [Tab. 25. fig. 2. cha.6] ariſing on either ſide out of the vpper part thereof, which are ioyned to the two greater productions of the Braine euen now ſpoken of, [Tab. 25. fig. 2. betwixt the two characters 2 and 3] and ſo of foure are made two, [Tab. 25. fig. 1, x] which afterward do accompliſh the ſpinall Marrow, from which all the Nerues of the whole body haue their originall as diligent inſpection doth ſufficiently prooue.

Galen acknoledgeth the truth of this.

And the ſame *Galen* affirmeth in the 13. chap. of his 8. Booke *de vſu partium* and in many other places where he ſaith, That all the Nerues which are attributed to the ſpinal Marrow do ariſe from the After-braine, ſo that according to his Anatomy the ſpinall Marrow is ioyned to the *Cerebellum*.

He is taxed by *Columbus*. Redeemed by *Varolius*.

Some there are and *Columbus* among the reſt, who heerein taxe *Galen*, affirming that no Nerue proceedeth from the *Cerebellum*. But, ſaith *Varolius*, *Galens* opinion may be after ſome ſort maintained to be true; but thoſe that find fault with him affirme that which is abſolutely falſe, becauſe the ſpinall marrow ariſeth out of two roots of the brain where two paire of ſinnewes are produced, and out of two roots of the After-braine which are ioyned to the former and do together fulfill or accompliſh the ſpinall Marrow; and ſo all the Nerues of the ſpinall Marrow do ariſe out of the *Cerebellum*.

Why the originals of the ſinnews grow into one.

And verily that this ſhould bee thus, it was profitable yea neceſſary; for the principles or originals of all things had neede to bee firme and ſtable. Now by how much any thing is more ſingle and ſimple, by ſo much without doubt it is more ſolid and firme; wherefore it behooued that the originall of all the ſinnewes ſhould be but one ſimple and ſingle originall. For if all the Arteries and Veines be reduced to one originall, the Arteries to the Heart, the Veines to the Liuer; it is agreeable to the wiſedome of Nature that the Nerues alſo ſhould proceede from one originall; becauſe theſe are three common Organs or Inſtruments of the body through which the Animall, Vitall and Naturall Faculties are by the helpe of ſpirites tranſported together with the vitall & naturall blood. And this both *Hippocrates* & *Plato* ſeeme to haue known.

Hipp. & *Plato* inſinuate ſo much,

Hippocrates who in the beginning of his Booke *De Natura Oſſium* writeth, that the Originall of Sinnewes is from the *Occipitium* which is the ſeate of the After-brain. And *Plato in Timæo* ſpeaking of all the Sinnewes writeth, that God diſpoſed the Nerues about the lower part of the Head, and compaſſed them with a ſpinal Marrow, which is of a ſubſtance like vnto theirs.

why the ſpinal marow ariſeth out of the cēter of the braine.

Now the originall of the ſpinall marrow was to bee out of the middle part of the Braine, [Tab. 25. fig. 2. b e, and character 4. do manifeſtly ſhew it] becauſe through it as it were through a common water-courſe the ſpirits which are perfected in the middeſt of the Braine were to be deriued into other Riuerets and ſo into the whole body. Wherefore their beginning was to bee placed in the center of the Braine neere the Store-houſe or ſhop of the ſpirits, whence they might receiue them as it were with a ful ſtreame; like as Anatomy teacheth vs, that the Arteries and the Veines do ariſe out of the middle of the Heart and the Liuer.

Obiection.

It will be obiected, that this Trunke which heere we call the Spinal marrow ought not to haue that denomination till it haue attained into the *Vertebræ* or racke-bones of the Chine, and therefore it is improperly ſaide that the Opticke Nerues doe ariſe from the Spinall Marrow. We anſwere, that we haue before ſufficiently ſatisfied this doubte in the 15. chapter of this Booke, yet for further contentment (if they will bee contented with reaſon) we anſwere by inſtance; doe not the Nerues of the Sight, Hearing and of the reſt of the ſenſes receyue their names from the Organes to which they are deſtinated before they touch thoſe Organes? yea whilſt they remaine within the ſcull? So alſo this Marrow may be called the Marrow of the backe or the Spinall Marrow before it enter into the Spine. For whilſt it remaineth within the ſcull it is diuided from the Braine, and in it may be obſerued proper Fibres belonging to it ſelfe alone.

Anſwere by inſtance.

Of the After-Braine or Cerebellum.

After we haue done with the ſpinall Marrow wee muſt come vnto the *Cerebellum* [Tab 25. Fig. 1. BB. fig. 2. Ch. 8, 9, 10] bared from the Membranes, which beſide two proceſſes called *Vermi-formes* which are parts of the ſubſtance therof, and beſide the two lateral parts

which

Table 25. Fig. 1. sheweth the Braine taken out of the Scull separated from the Dura Meninx and inuerted, whose right side exhibiteth the Originall of the Spinal Marrow and the seauen Conjugations of the Sinnewes of the Braine, according to the ordinary receiued opinion: but the left side sheweth their true originals.

Fig. 2. sheweth the Braine inuerted, & the partes thereof in the Basis distracted, as also the Originall of the Spinall Marrow out of the braine and the After-braine, the largenesse of the Ventricle, and the originall of the Opticke Nerue out of the Marrow.

TABVLA. XXV.

FIG. I.

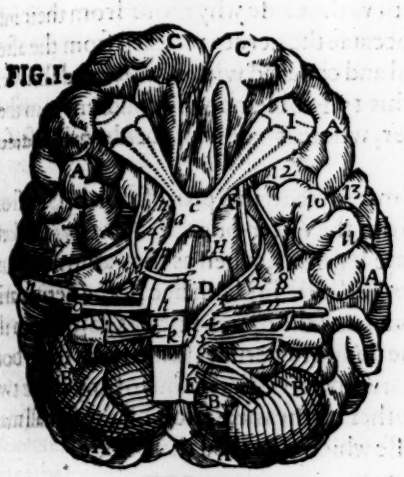


FIG. II

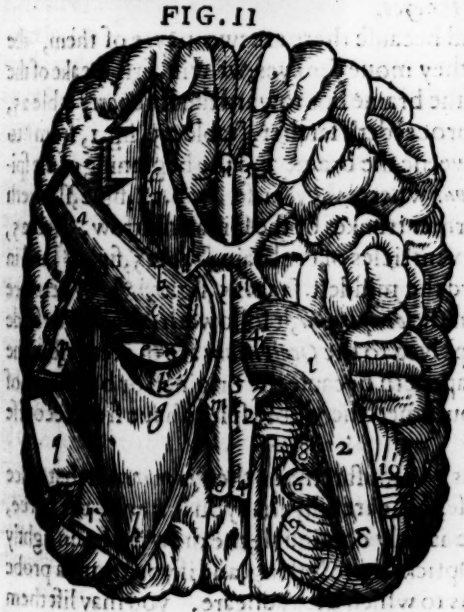


A A A. The Braine.
BBB, the After-brain.
CC, the swellings of the braine commonly cald the *Mamillarie* processes.
D, the beginning of the Marrow of the back, as it is commonly beleued.
E, the termination or end thereof in the Scull.
F, the originall of the Organes of smelling according to the vulgar opinion.
H, the originall of the Opticke Nerues, as it is commonlie receiued.
I, the coate into which the Opticke Nerue is inserted.
2. The second paire of sinnewes.
3,4,5,6,7. The coniugations of the sinnewes, whose Originall *Vesalius* himselfe attributeth to the beginning of the Spinal Marrow.
8. A branch of the third coniugation as Anatomistes doe beleeue which passeth forward, but we take it to be the third Coniugation.
9, A branch of the fift coniugation according to *Vesalius*, but we esteem it to be a coniugation of it self, and therefore cal it the eight paire.
10,11,12,13. The barke or shell of the Braine; for 8,9, 10, 11. is the verie marrow of the Braine it selfe, and these two are not cõtinual but only contiguous, or touching one another.
a,b. The whole Optick Nerue, and at *b.* is the reflection of the Nerue to the back-part of the Spinall Marrow.
c, The coition or concurse of the Optick Nerues.
d e. A part of the second Nerue not commonly knowne, whose originall is at *e.*
f,g,h. The Marrow of the Braine lengthened and determining in the spinall Marrow.
k. The transuerse processe of the After-braine which is called the *Bridge*.
i,i. the Auditorie Nerue arising out of this processe.
l,m. the passage of the Organ of smelling lurking between the vpper and middle prominence of the Braine, and at *l.* is his originall.
n, the middle prominence of the Braine diuided from the rest of the Braine.
o, the beginning of the backward prominence of the brain from whence the middle was dissected.
p, the intercussation which the Optick Nerue maketh with the Nerue that mooueth the eye.

The Second Figure.

1,2,3. The halfe of the Spinall marrow drawn to one side.
4,5. the coniunction of the same marrow with the ventricle
6. A portion of the spinall marrow growing out of the After-brain.
7. the Optick Nerue reflected in the backpart of the spinall marrow and entering into the cauity of the Ventricle.
8,9,10. the leftè side of the After-braine from which the right side is remooued.
11,12. A slit going vnto the second Ventricle, which slit is formed partly by the bodie of the Arch, partly from the inner part of the Spinall Marrow.
13,14. The Coniunction of the right and the left sides of the Braine by the Callous body.

a. The right part of the Spinall Marrow reflected vpward to his owne side, that so the originall therof which is in the cauity of the Ventricle might be perceyued. *c,b.* The beginning of this Marrow as it respecteth the hollownesse of the Ventricle. *d,e.* The Optick Nerue reflected about the roote of the Spinall Marrow. The first originall of the Optick Nerue. *f g,b.* The whole Cauity of the Ventricle, *f* sheweth the Anterior, & the middle, and *h* the Posterior Cauity hollowed in the Braine. *i,k.* The complication of vessels cald *Plexus Choroides* about the roote of the spinall Marrow in the ventricle. *l,m.* A portion of the *Basis* of the brain which together with the Spinall Marrow maketh the cleft which entreth into the ventricle. *n,o.* the length of the callous body which ioyneth together the two sides of the Braine. *p,q,r.* Portions of the braine reflected backward that the cauity of the ventricle might better be perceyued.

which resemble two bowles closed together, of which wee spake sufficiently before in the 14. chapter of this booke: there remaineth yet another processe thereof to be exhibited & manifested vnto you.

The processe called the Bridge.

This processe is a very notable one, [tab. 25, figure. 1, k] arising on eyther side out of the *Cerebellum* neere the trunks wherof the spinall marrow is amassed, and runneth ouerthwart forward and downeward, by the mediation whereof this After-braine imbraceth the fore-part of the spinall marrow after the same manner that the transuersall or ouerthwart muscles of the *Larynx* making the third paire of common muscles doth imbrace the back-part of the beginning of the *œsophagus* or Gullet and thence are called *œsophagæi*: and this processe is distinguished by a course of ouerthwart fibres with a kinde of eminency from the right fibres of the spinall marrow.

This processe *Varollius* calleth *pontem Cerebelli*, the bridge of the After-braine, from the similitude it hath with a bridge, because vnder it the spinall marrow runneth as a streame runneth vnder a bridge.

How the auditory nerue ariseth out of the Bridge.

At this processe the *nerue of hearing* hangeth and hence ariseth, [table 25, fig. 1, ii] so that we may boldly auouch that the *Cerebellum* is also the first originall of the sense of hearing. And this beginning of the auditory nerue teacheth vs the cause why more from their infancy are deaf then destitute of any other sense; for because the nerues proceed from the after-brain and run no long course, they are easily filled and choaked with *Mucous* and slimy excrements; & this is the reason, as saith *Cassius* in his 17 Probleme, why children from their infancy loose their hearing of both eares together, whereas vpon an accidentall disease it is more vsuall to haue one alone vitiated.

Two pretty questions resolued.

Seeing therefore almost halfe of the spinall marrow and this processe or bridge from which the auditory nerue ariseth do proceede from the After-braine; *Varollius* thinketh that *Galen* hath great wrong to be taxed by the late Writers, when as they affirme against him, that no nerue hath his originall from the *Cerebellum*: for saith hee, some nerues arise onely from the braine and not from the After-braine as the optick sinewes; some from the After-braine only and not from the braine as the auditory nerues; some from them both together as the nerues of the spine: but no nerue ariseth immediately out of any of the two principles but all out of their owne principles eyther by the mediation of the spinall marrow or by the mediation of that transuerse processe which we called the Bridge.

Galen iniured by the *Neoterists*.

Varollius.

Of the Nerues of the eyes.

Next followeth the nerues of the eyes, and because there are two payre of them, the one called *optici*, the other *motorij* because they moue the eyes; we will first speake of the *opticks*. They say they arise out of the basis of the braine but toward the forepart, [table 25, fig. 1, i] whereas indeed a great part of them proceedeth farther, [table 25, fig. 1, from a to b] and lurking in a certaine space formed betweene the braine and the beginning of the spinall marrow, they runne out toward the *occiput* where they arise [tab. 25, fig. 2, sheweth their originall] out of the beginning of the former trunkes of the spinall marrow, [tab. 25, fig. 2, b c] where they respect the cauity of the ventricles of the brain, [tab. 25, fig. 2, f] and in the backpart thereof they are reflected toward the middest. [tab. 25, fig. 2, d e] Wherefore seeing the originall of these nerues is almost in the *occipitium*, it followeth (as also wee finde it true by daily experience) that Cauteries applyed to the *Occipitium* are of great vse in the diseases of the eyes: which out of question hapeneth because the originall or beginning of the opticke sinewes beeing depurated and confirmed the visible spirits haue freer recourse vnto the eyes.

The common receiued originall.

The true originall.

Why Cauteries at the necke helpe the eyes.

How to demonstrate the Opticke nerues.

If you would demonstrate these sinewes you must remoue the *Pia mater* at that place where the Opticks are commonly saide to arise; but carefully that you hurt not the nerue, & then you may perceiue that the brain there is only contiguall; the draw the brain lightly forward from the marrow till you finde the Opticks there lurking, and if you thrust a probe without violence betweene them and the parts to which they adheare, you may lift them from the subiected parts till you come to their originall, and withall you shall perceiue where the spinall marrow taketh his beginning out of the braine. They say commonly that the mouing nerues [ta. 25, fi. 1, Ch. z] haue their beginning neere the Opticks, a little more outward; but if you dissect a part of the brain toward the midst you shal perceiue them distinguished from the brain to attaine to the middle of the head & to passe vnder the Opticks after they haue made an intercussion, [Table. 25, figure. 1, d] that is, haue crossed one the other, and do arise at the inner part of the beginning of the spinall martow, [Table. 25,

The mouing nerues.

fig.

figure 1.[c]] and in their originall are so vnited that they touch one another in one corner, which haply is the cause why both the eyes are together moued to the same side. Why both eies moue together.

That the rest of the coniugations of the sinewes of the braine do yssue from the Spinall marrow, *Vesalius* is content to affirme, excepting onely the third. *Columbus* acknowledgeth that third with all the subsequent coniugations to arise from the said marrow, and for the two first paires we haue euen now proued their originall: it remaineth that we proceed to the instruments of smelling.

The instruments of Smelling or the Mammillary processes.

The instruments of smelling or the *anterior* processes of the braine which proceed outward betwixt the optick nerues vnto the fissure of the spongie-bone scituated at the toppe of the nose, are commonly esteemed to arise out of the Basis of the braine [tab. 25. fig. 1.[r]] neare the coniunction of the opticke nerues [Tab. 25. fig. 1.[c].] But the truth is, that Anatomists hitherto haue shewed onely the one halfe of these instruments; for beside that they doe shew [table 25. figu. 1. from [m] forward] they proceede as much more [Table 25. figure 1. from [m] to [l]] lurking betwixt the forward and the middle swelling of the braine, for their progresse is backeward, and by how much they reach further, by so much is the distance more betwixt them. They are also by little and little attenuated, growing thinne vntill they determine into a sharpe poynte at the sides of the braine almost at the vtmost limite thereof [Table 25. figure 1. at n] which is aboue the holes where the ayre beateth into the eare, for this is the place of their originall. Their cõmon receiued originall.

And hence haply it is that if the smelling bee intercepted; the hearing also is somwhat affected; for we see that when vpon a cold or murr (as we cal it) the nose is stopped and the smell hindred, the hearing also is somewhat offended: wee also manifestly perceiue that when wee sneeze or blowe our nose or retayne our breath by shutting vp our nosthrils, the hearing is also instantly interrupted, and those that loose their smell doe verie easily become deafe: it may also bee that from this sympathy that Probleme of *Aristotle* the fift of the 11. Section, and the 23 of *Cassius*, *Why those that be deafe do speake through the nose* may be assoyled. Their true original. Of the simpathy between hearing and smelling.

Of the Ventricles of the Brain.

These things being thus demonstrated, and the eyes with the optick nerues being drawn each into their owne side, you must lengthwise cut into two partes the bridge of the *Cerebellum* and the spinall marrow, then must you remoue the *Cerebellum* quite away, and one part of the spinall marrow so deuided lengthwise as we sayde before must be drawne to his owne side, and one side of the braine both before and behind must be cut to shew the magnitude and figure of the ventricles thereof, for this Administration sheweth a great difference in the scite, magnitude, forme, number and vse of them from the common demonstration. How we must proceed in this kind of section.

The receiued opinion is that there are foure ventricles, *Arantius* in his obseruations accounteth six; foure acknowledged by the antients and vnder these two other; but indeed and trueth by how much the number is increased, by so much is the error the greater, there being in trueth but two, for the braine both of man and beasts being double, as first *Hippocrates* obserued in his Booke of the *Falling sicknes*, and after him *Aristotle* in the 10. chapter of his fourth booke *de Historia Animalium*, it seemeth equall that each part should haue a ventricle. *Hippocrates* *Aristotle.* For these two which they place in the forepart of the braine are as wel seated in the middle and in the hinde-part as they are before: for hetherto scarse their ourth part hath beene demonstrated, their magnitude being answerable & proportionable in respect of their forme to the magnitude of the whole braine, and the swelling prominences thereof: neither is it to be doubted but that the cauities of the braine while the creature is aliue are farre larger then after he is dead, because after death the braine that was streatched and as it were extended with spirites, when those spirites are vanished falleth into it selfe and so the cauities are lessened and contracted. The magnitude of the ventricles.

Now the braine is on either side long, and where the two sides the right and the left doe regard each other it is plaine and depressed, in other partes it hath sphericall or round productions or prominencies answerable to the hollownes of the bones wherein it is contayned.

The *anterior* or forward prominence filleth the cauity formed by the forehead bone, a part of the spongy bone, the bone of the *sinciput* or side of the head and the wedge-bone; the middle and lower prominence filleth on both sides the cauity formed by the backepart of the wedge-bone, the forepart of the stony-bone and the bone of the temples. The *anterior* prominence.

The posterior

The *poſterior* or backward prominency filleth the cauity made by the vpper part of the *Occipitium* and the latter part of the wedge and ſtony-bones. And to theſe prominences the cauity of the ventricles is anſwerable; for from the forward prominences there runneth a notable boſome or hollownes, euen vnto the latter or backward; which *Sinus* or hollowneſſe is ſo farre diſtant from the outſide of the braine in the back-part as it is in the forepart.

But when it attaineth vnto the angle or corner which is in the vpper part of the ſtony-bone, it is reflected to the middle and lower prominence of the braine and after the ſame manner is excauated or hollowed in that prominence or production as it is in the *anterior* or *poſterior* parts.

But why is the ventricle thus figured? why did Nature neglect the round figure and reflect it thus into it ſelfe? *Mercurialis* maketh anſwere; That as in a pond or Lake wherein water may rage, men do frame out ſome oblique angles, or corners wherein his direct and impetuous courſe might be broken or as it was in that Hauen into which *Aeneas* put in a ſtorme, againſt the ſides whereof *Virgil* ſaith:

omnis ab alto
Frangitur, in que ſinus ſcindit ſeſe vnda reductos.
The waues are broken from the Mayne,
And in the Creekes are cut in twaine:

So Nature to interrupt the violent motion of the ſpirits, leaſt they ſhould offend the wals as it were the ſhores of the ventricle, cut out theſe Angles or ſet out theſe Peeres againſt which or in which their violence might be broken.

Furthermore the braine, which without the compaſſe of the ventricles is very thicke (conſidering the ventricles as they are commonly demonſtrated;) if you haue a reſpect to theſe two ventricles as we exhibite them is farre thinner then it is in other parts, and like a ſhell compaſſeth theſe two cauities, which truely might be called but one ventricle were it not diſtinguiſhed by the interpoſition of that body which is called *Corpus Calloſum*; [table 25, fig. 2, m n o] & theſe only are the ventricles of the brain. Now what thoſe parts are which are commonly called the third & the fourth ventricles it remaineth that we ſhew vnto you.

What are the 3. and 4. ventricles commonly ſo called.

The whole braine as alſo the ſpinall marrow is diuided into two parts, and is onely ioyned in the middle and lower part by that Callous body we ſpake of euen now, [Table 5, fig. 2, m n o] which is nothing elſe but the braine in that part conioyned. For where the right & the left parts were to be ioyned they are bent a little outward, afterward growing white they are reflected to the middeſt and ſo vnited. This vnion hath a kinde of conuexity or embowed figure proportioned to the conuexitie of the braine, which alſo is as long as the Sagittall ſuture or ſeame.

The *Corpus Calloſum*.

Some thinke that it is harder then the other parts, but we thinke it is as ſoft as the braine it ſelfe, and is very white like the inward parts or ſides of the ventricles. The interior part of this vnion is ordinarily called *Fornix* or the Arch.

The Arch of the Braine.

The two Trunkes produced from the braine being become round do touch another, and ſo bend ſomewhat forward; but againe returne backward toward the hole of the *Occipitium*, and becauſe they are round bodies they make betwixt themſelues in their firſt contaction a light anguler or cornered cauity vpon which the Baſis of the braine beeing vnited doth leane it ſelfe, ſo that from the mutuall touch of the bodyes before ſpoken of that ſpace is formed which they call the third ventricle, which to ſay truth is without the braine and formed not by any intention of Nature but of neceſſity, becauſe of the coniunction of theſe bodies.

The third ventricle.

In the vpper part heereof towards the ſides there appeare two long ſlits or fiſſures which run almoſt through the middle circumference of the trunkes of the ſpinall marrow, and ſo paſſe into the ventricles of the braine, and by the way of theſe fiſſures the ventricles haue an outlet vnto that they call the third ventricle. And becauſe the foreſaide trunkes doe reach as farre as to the Saddle of the wedge-bone where the Tunnell is, therefore it is commonly ſaide that the *anterior* paſſage of the third ventricle reacheth vnto that part.

The fourth ventricle.

The fourth ventricle ſo called, is a *Sinus* or hollowneſſe betwixt the lower part of the *Cerebellum* and the vpper trunks of the ſpinall marrow, where the ſame ſpinal marrow is caued or hollowed like a writing pen. This *Sinus* or boſome is made of the two trunks proceeding out of the *Cerebellum* for the framing of the ſpinall marrow, and is lengthened out of the diſtance of both thoſe propagations of the After-braine. For before they bee vnited with thoſe two other greater trunkes which ariſe from the braine it ſelfe, they paſſe along aboue them a little diſtant one from the other. So that this cauity like as the other, ariſeth

rather

rather vpon necessity of the position of the parts then from any foresight or intention of Nature; because like as the third so also this fourth ventricle is scituated without the braine and the *Cerebellum*.

That hole which is called the latter *foramen* of the third ventricle, which some make to be like vnto the fundament and will haue to enter into the fourth ventricle; is nothing else but a space made by the contraction or mutuall touching of the foure trunkes of the spinall marrow where the trunkes of the *Cerebellum* are bent downeward and adheare or cleaue to the Trunkes arising from the braine. The fundament of the Braine.

Here appeare foure orbicular prominences commonly called the Buttocks and the Testicles of the braine, which they commonly affirme to be within the braine though indeed they are without. And these *Varollius* thinketh to be the true originals of the spinal marrow: and that the buttocks are nothing else but portions of the roots of the spinall marrowe proceeding out of the *Cerebellum*, like as the Testicles are small portions of the roots proceeding from the Braine. The buttocks and Testicles. The true originals of the spinal marrow after *Varollius*

Concerning the vse of the ventricles, the common opinion is, that they are the conceptacles or receptacles of the Animal spirits as the left ventricle of the heart is the place of the vitall spirit. But although we will not deny that there may bee many vses assigned to one and the same part; (and therfore *Galen* in the tenth chapter of his eight book *de vsu partium* was of opinion that the vpper ventricles did serue for the preparation of the spirits & also for the expurgation of superfluities,) yet we are of opinio that these ventricles are the receptacles of the phlegmatick humor which is ingendered in the braine, which through the *infundibulum* or Tunnel is conuayed to the phlegmatick glandule and so purged away. For the ventricles haue no where any outlet but onely at the Tunnell: but for the Animall spirits we think that they are disseminated through the whole substance both of the brain & of the After-brain. And this we shew first by the testimony of *Hippocrates*, who when he had deliuered that man consisted of foure humors, and did asigne to euery one their proper place he saith; That the place of the spirits and of the bloud is in the hart, of yellow choller in the Liuer, of blacke in the spleene. And if the place of phlegme be in the braine there must of necessity be a cauity which may containe it; such as is the ventricle in the heart and the bladder of gall in the Liuer: Now beside these two ventricles there is in the braine no cauity at all. The vse of the ventricles. *Galen*. That the ventricles receiue the phlegme. *Hippocrates* his first reaso.

Secondly, it is proued by the general vse of Glandules which is to sucke vp and consume superfluous humidity. Whereas therefore in these ventricles there are Glandules found in that complication or web of vessels therein disposed; it followeth that phlegme is therein gathered, which distilleth out of that textute or web into the ventricles and there is heaped together; (for they are not able to consume so great a quantity) otherwise both the Glandules should be in vaine added by Nature, and their vse and commodity assigned by *Hippocrates* should be idle and of no vse. 2. reason.

Furthermore it is acknowledged by all men that the phlegme doth distill from the braine through the Tunnell vnto the Pallet. Now the beginning of the Tunnell is in the ventricle, neyther is there any passage from any part of the braine vnto the Tunnell vnlesse it be out of the said ventricles. 3. reason.

Fourthly, it is proued by an argument taken from necessity: because this phlegmatick excrement did require great and large cauities. For if there had beene no conuenient place wherein a notable quantity thereof might be stabled or heaped together; wee should haue beene troubled with continuall spitting and spawling (euen as they in whose bladders the vrine is not collected and retayned doe continually auoid their water by drisling or drops) and so our speech and other noble actions interrupted. And hence it is that in sleepe a great quantity of this phelgme being collected, after we awake we auoid it plentifully in a short time. Now this quantity because it could not be contained within the *Dennes* or hollow cauities of the nose behooued to haue some other receptacle in the braine wherein it might be reserued till conuenient time of euacuation. 4. reason. Many instances from our sence.

We do also sensibly perceiue that if a man be desirous to spit and therefore sucke the vpper part of his Pallate, he shall gather great quantity of this phlegmatick excrement into the cauity of his mouth and thence spit it foorth. But if hee againe instantly striue to spit he shall auoid a lesse quantity; and so lesse and lesse till by sucking hee can gather no more spittle. But after a short interim or interposition of time the excrement wil againe fal into his mouth; which is a most euident signe that this matter is in some notable quantity collected

colected or gathered together before it be auoyded as it is in the Vrine & the excremẽts of the belly.

What we conclude.

We conclude therefore that these Cauities of the ventricles do receyue the foresaid excrements, because those Glandulous complications doe enter into them, and out of them onely are the passages by which the moysture is auoided.

Mercurialis his obiections.

Mercurialis opposeth on this manner. How may it be that so thicke, cold and obscure or dull a humor so contrary to the spirits should be collected in that place where the spirits themselues which are pure and subtle bodies are as it were in an Ouen baked & perfected? Moreouer, the causes of an Apoplexie, Epilepsie or Falling sickenesse and the *Incubus* or Night-Mare are by all Physitians acknowledged to be, when as Flegm or Melancholy, or crasse and thicke winde is reteyned in the Ventricles, which stopping them vp either wholy or for the most part, do strangle the spirits therein conteined, which (as *Galen* saith in his third Booke *De Locis affectis*) *Hip.* signifyed in darke and obscure words in the end of the second Section of the sixt booke *Epidemian*, where he writeth, *That the disease called Melancholia hapneth when the humour falleth into the seate of the minde, and the Epilepsie when it falleth into the body of the Brain.*

Hippocrates.

Plato.

Plato also consenteth with *Hippocrates* in *Timæo* where he writeth, that the Falling sickenesse happeneth when Flegme mingled with Melancholy entreth into the diuine cauities of the braine. *Varolius* maketh answere on this manner. For the Causes of the Apoplexie, Epilepsie and *Incubus*, although I sometimes read in *Hippocrates* as in the Ninth Text of his Booke *De Glandulis*, that the Apoplexy is occasioned by the *Corrosion* of the braine, and in the nineteenth and twentith Texts of his Booke *De Flatibus*, that the Epilepsy is caused when the blood is disquieted and defiled in all the veines, as also vvhen the same veines are obstructed. And that I reade in *Galen* in the seauenth Chapter of his third booke *De Locis Affectis*, that hee doubted whether the Epilepsy were made by an obstruction of the ventricles of the Braine, or of the Spinall Marrow, and therefore that I willingly graunt that these diseases may haue these causes: yet I conceiue that it will not abhorre from reason to thinke, that the Ventricles (though the Animall spirits bee conteyned in them) are sometimes so fulfilled with a viscid humour or thicke wind, that the first roote of the Spinall Marrow may be compressed by the aboundance thereof, so that the transportation and affluence of the spirits thereunto may bee interrupted and intercepted, and consequently the whole bodye depriued of sense and motion. Like as the bladder in the suppresion of the Vrine being beyond measure distended lying hard vpon the guts, the auoyding of the excrements is hindred.

Varolius his answere to *Mercurialis*.

The causes of the Apoplexie *Hippocrates*. *Galen*.

Do not contradict *Varolius* opinion.

Another satisfaction.

And if this answere will not please the pallate, I will say with *Galen* in the place before quoted, that the Epilepsy and such like diseases do proceede by the obstructing or immuring of the Spitits, which happeneth when the beginning of the Spinall Marrowe is choaked by an vnnaturall confluence of humours vnto it. And this opinion is confirmed by the Dissection of the heads of such men as dye Apoplecticall, in the Ventricles of whose brains there is not found any greater quantity of excrements then is commonly found in other men.

This opinion. Confirmed by Dissection

Furthermore, they Obiect that in the Epilepsy, the Apoplexy and the *Incubus* the Animal spirits residing in the Ventricles of the Braine are strangled or their outgate hindred. *Varolius* answeres that these diseases happen not from any humour or winde atteyning any way vnto the Ventricles, but by reason of a great quantity and notable thickenesse, or sudden eruption. Wherefore euen as the excrements descending by the pallate and the nose do not offend the taste or the smell if they passe through those Organs moderately and according to Nature, but do either hinder or vtterly intercept their operations if they exceede the measure and proportion of Nature in quantity or in quality: so we thinke we are to conceiue of the excrements accruing vnto the ventricles of the brain or receding there-from.

Another Obiection. Answered.

That the spirits are in the substance of the Braine. *Galen.*

Now that the Spirits are dispersed through the substance of the braine, we proue by the testimony of *Galen* in the 13. chapter of his eight booke *de vsu partium* where hee sayth, That the Animal spirite is in great quantity conteyned in the body of the braine, as also of the *Cerebellum* to which he attributeth the Original or beginning of the nerues of the whole body, and therefore he inferreth that it is necessary it should bee filled vvith the aboundance of spirits.

If therefore the *Cerebellum* which hath in it no cauity at all doth yet conteyn in his sub-

ſubſtance plenty of ſpirits which flow from it to ſo many nerues remooued by ſo great diſtances therefrom, why may we not beleeue that after the ſame maner yea a great deale rather the ſpirites may bee conuayed without manifeſt cauities out of the braine to a fewer nerues and thoſe not far diſtant from it but euen at hand? Seeing therefore that the Animall ſpirits can ebbe and flow without any ſenſible paſſage; why may wee not aſcribe that vnto the ſubſtance of the braine which others haue aſcribed vnto the ventricles although they haue not duely obſerued them? The concluſion.

Of the web or complication called Plexus Choroides.

Finally, the complication or web of veſſels which they call *Choroides* or the Nét which is in the ventricles of the braine; [table 25. fig. 2. ik] ſeemeth to be altogether glandulous or kernelly, ſo that both in ſubſtance and colour it may be likened to the Pine-glandule wee ſpake of in the 12. Chapter; yet if you handle it nicely and mark it diligently you ſhall find that it is nothing elſe but a heape of broade and long membranes growing out of the *pia mater* of the braine, at the one ſide whereof through out their whole length hangeth a little thicke veſſell full of excrementitious moyſture, through which exceeding ſmall veſſels are deriued: & if we may compare little things with great, it is like a gut tyed vnto the meſentery, yet for the proportion there are in it more glandules then in the meſentery of the lower belly. And this manifeſtly appeareth in their heads whoſe braines are very moyſt & therefore ſayeth *Varolius*, it were more agreeable to their nature to call them Glandulous then *Net-like complications*. Of the *Plexus Choroides*. What it is.

And if any man doubt whether the ſubſtance of them be ſuch as we haue ſaide, wee remit him vnto his own ocular inſpection, ther being no argument of greater valliditie. For ſayth *Varolius* in all carkaſſes which we haue opened, we haue found theſe glandules full of ſuch a muddy moyſture as we finde in the reſt of the Glandules of the body. Albeit *Archangelus* doe thinke that ſuch excrements are onely found in diſeaſed braines. That it is glãdulous.

The vſe of this glandulous complication ſeemeth to be; that like other glandules it might ſucke vp the ſuperfluous moyſture of the brain, for that is the office of the glandules in the whole body: yea *Hippocrates* himſelfe in the ſecond Text of his Booke *de glandulis*, proueth by an induction of the particular glandules of the whole body, that when the body aboundeth with ſuperfluous humidity it is thereof exonerated and diſcharged by the glandules; yea he proceedeth ſo far as to ſay that the whole ſubſtance of the braine is glandulous. The vſe of this complication.

Now concerning the reſt of the parts of the braine of which in this new demonſtration or diſſection wee haue made no mention, you muſt conceiue of them as their hiſtories are deſcribed before.

But if a man bee deſirous in this kinde of Section to demonſtrate or exhibite to the ſpectators all the parts, then muſt he proceede in this order. After he hath taken away all the bones of the head by ſawing them through the length aboue and beneath, before and behinde; he muſt firſt make demonſtration of the *Sinus* or veſſels of the *dura meninx*. Afterward turne the head and at the Baſis of the braine ſeparate the Meninx from the ſpinall marrow, yet muſt he leaue portions of the Meninx about the nerues that they be not broken, for then you cannot follow them to their originall. How this ſection muſt be adminiſtred.

Vnder the membrane which inueſteth the ſpinall marrow there appeareth a texture or web of veſſels diuerſly croſsing one another, which they commonly call *Rete-mirabile*, the Wonderfull Net; then the flegmatick glãdule commeth in ſight which is almoſt ſquare, & the neck of the Tunnel which are ſcituated without the thick Meninx. From hence our eye paſſeth vnto the membrane of the ſpinall marrow and the marrow it ſelfe; which being lifted vp we behold the buttockes, the teſticles, the paſſage into the fourth ventricle and the fourth ventricle it ſelfe, all which are without the braine. Wee ſee alſo the After-braine, the proceſſes thereof, the auditory nerue, the mouing nerues of the eye together with the opticks, the organs of ſmelling, the two ventricles of the braine together with their paſſage into the Tunnell, as alſo the Callous body, the Arch, the Complication called *Choroides*, and the Pine-glandule. And thus much concerning *Varolius* his newe way of diſſecting the head, which we haue added as an accompliſhment to this Booke of the braine, becauſe indeed after this manner all the parts thereof are beſt ſhowne and to beſt purpoſe. Now we proceed to the Controuerſies. How the particular parts of the braine ariſe.

¶ A Dilucidation or Expoſition of the Controuerſies concerning the Braine and the Parts thereof.

QVEST. I. *Whether the Braine be the ſeate of the Principall Faculties.*

A diuiſion of the Animal Faculties.

THE Animall Faculties are by the Phyſitians diſtinguiſhed into Faculties of *Senſe*, Faculties of *Motion* and *Principall* Faculties. The ſenſitiue Faculty is double, one Externall whoſe obiect is ſingular or one; the other Internall vvhoſe obiect is common or manifold: this Internall Facultie the Philoſophers call the Primary or *Common ſenſe*; and this is it which alone maketh the differences of *Images* as wee call them or Abſtracted Notions. She ſitteth in the ſubſtance of the Braine as in a throne of Maieſty beholding the Formes or Ideas of all things vnder her feet. This is ſhee that diſcerneth betwixt ſweete and bitter, and diſtinguiſheth white for ſweete. This common ſenſe *Ariſtotle* compareth to the center of a circle, becauſe the ſhapes and formes receiued by the outward ſenſes are referred or brought heereunto as vnto their Iudge and Cenſor.

The common ſenſe.

The Imagination.

After this inward ſenſitiue Faculty do follow the principall Faculties; and firſt of all the Imagination which conceyueth, apprehendeth and retaineth the ſame Images or repreſentations which the common ſenſe receiued; but now more pure and free from all contagion of the matter, ſo that thogh thoſe things that moue the ſenſes be taken away or other wiſe doe vaniſh, yet their footſteps and expreſſe Characters might remaine with vs. And this conception or apprehenſion we call *Phanſie*. By this *Phanſie* that ſupreme & ſoueraign *Intellectual* power of the Soule is ſtirred vp and awaked to the contemplation of the Ideas or Notions of vniuerſall things.

The Intelligence.

The memory.

Finally, all theſe are receyued by the Memory, which as a faithfull Recorder or Maiſter of the Rolles doth preſerue, ſtore vp and diſpoſe in due order all the forenamed Notions or abſtracted formes. And theſe are the Principal Faculties according to the Philoſophers and the Phyſitians, concerning which we haue three things to enquire.

3. Queſtions.

The firſt, whether the Braine be the ſeate of them all. Secondly, whether in the braine theſe diuers Faculties haue diuers Manſions. And laſtly, whether theſe principall Faculties do reſult or ariſe out of the temperament or from the conformation of the Brain, and whither they be Similer or Organicall.

Diuers opinions.

Herophylus. Xenocrates. Eraſiſtratus. Empedocles. Moſchion. Blemor.

Concerning the ſeate of the reaſonable Soule the opinions of the Philoſophers and Phyſitians are very different. *Herophilus* placeth it about the baſis of the braine. *Xenocrates* in the top of the head. *Eraſiſtratus* in the Membranes of the braine. *Empedocles*, the *Epicures* and the *Egyptians* in the Cheſt, *Moſchion* in the whole bodye. *Heraclitus* in the outward motion. *Herodotus* in the eares. *Blemor* the Arabian in the eyes, becauſe the eyes are the diſcouerers of the minde, and ſo fitted and compoſed to all the affections and affects of the ſame, that they ſeeme to be another Soule, for when we kiſſe the eye wee thinke wee touch the ſoule it ſelfe.

Strato Phyſicus. Prouerbe.

Strato the Naturaliſt thought the ſoule inhabited in the eye-browes, becauſe they are the ſeate of *pride* and *Diſdaine*, and therefore the Poets were woont to call pride the Eye-brow, and we commonly ſay of an inſolent man, that we ſee pride ſitting vpon his browe.

More-

Moreouer from the haires of the browes the Phisiognomers gather signes of the disposition of the minde. For if they bee straight it is a signe of a soft and flexible disposition; if they be inflected neare the nose they are a signe of a scurrulous Buffon; if they bee inflected neare the temples they argue a scoffing Parasite; if they bend all downewards they are an argument of an enuious inclination. The *Perepatetickes* and *Stoicks* doe all of them place the faculties of sence and vnderstanding in the heart, because say they that that is the principle or beginning of motion is also the originall of sence: But the heart is the principle of all motion, because it is the hottest of all the bowels and a liuing fountaine of Naturall heate. Moreouer, in passions of the minde, as Agonies, Feares, Faintings and such like, the spirites and the heate returne vnto the heart as vnto their Prince. And for this they bring the authority of diuine *Hippocrates* in his golden Booke of the heart, where hee sayth, *The Soule of a man is seated in the left ventricle of the heart, & from thence commandeth the rest of the faculties of the Soule, and it is nourished neither with meate nor drinke from the belly, but with a bright and pure substance segregated from the bloud.*

Strato his Phisiognomy of the eie-browes.

The opinion of the *Peripatticks.*

Hip. authority.

We with *Hippocrates*, *Plato*, *Galen* and all Physitions, do determine that. The braine is the seate of all the Animall faculties, for if the braine be offended, wounded, refrigerated, inflamed, compressed, or after any other manner affected, as it is in a phrensie, *Melencholia*, *Charos*, *Chatoche*. or *Epilepsie* wee may discerne a manifest impeachment of all the Animall functions, which if wee desire to cure, wee apply our remedies not to the heart but to the braine. But if the heart were the seat of the principal faculties then in all affections or notable distemper thereof, all the functions should be interrupted, because the action is from the Temperament. But in a Hecticke Feuer in which there is an vtter alienation of the Temperament, the voluntary and principall faculties remaine sound and vntainted. When the heart is violently moued as in Palpitation, neither is the voluntary motion of the parts depraued nor reason it selfe. Who will deny that the vitall faculty is oppugned by a pestelent aire, the byting of a venomous creature, or by taking of poyson? but al those that are so affected do yet enioy their sence and reason. If (saith *Galen* in his 2. booke *de placitis Hippocratis & Plat.*) you beare the heart and presse it, you shall perceiue that the creature will not be hindred in his voyce, his breathing or any other voluntary action.

The opinion of the Physidons.

That the braine is the seat of the Animal faculties.

And whereas *Hippocrates* placeth the Soule in the heart, happly hee speaketh after the manner of the common people as hee vseth oftentimes to doe; now the vulgar imagined that the Soule was in the heart. So he calleth the *Diaphragma* or Midriffe φρένας the Minde, when as notwithstanding those Vmbles haue no power whereby the creature doth vnderstand any thing, as he teacheth in his Booke *de morbo Sacro* or the Falling sicknes.

Hip. expounded.

Or we say that by the Soule in that place hee vnderstandeth the chiefe instrument of the Soule, to wit, the *Heate*. So in his first booke *de diæta* he commonly vseth the word *Soule* for *Heat*, as when he sayth *That the Soule of man is encreased euen vnto his death.* And againe in the same Booke *The Soule creepeth into a man being mingled of fire and water.* Where by the Soule I vnderstand the heat throughly dewed or moystned with the in-bred and primigenie moysture and the spirits. And that in his Booke *de Corde* by the Soule hee vnderstandeth the heate, those words do declare, where he sayth, That the Soule is nourished by the most pure and defæcated bloud. Now in his first booke *de Diæta*, hee writeth that the Soule cannot be altered neither by meats nor drinks. VVhich place because it is as bright as the Sun in his strength and worthy to be written in golden Letters, wee will here transcribe. *The causes of all those things whereby the Soule is altered, are to be referred to the nature of the passages through which it penetrateth. For as the vessells are affected wherein to it voteth and to which it falleth and with which it is mixed, such is their condition; and therefore wee cannot alter them by dyet, for it is impossible to alter or change the inuisible Nature.*

Hip. often vseth the word Soule for heate.

An elegant place of *Hip.* concerning the immortaliry of the soule.

In his Booke *de morbo sacro*, he affirmeth, that in the heart there is no wisedome or intelligence, all sayth he is in the power of the Braine. From the braine we vnderstand, doote and grow mad, as it is hotter, or dryer, or colder.

Galen in his third Booke *de Placitis*, conuinceth by many arguments that the braine is the seate of all the Animall faculties. And in the fourth Chapter of his third booke *de locis affectis* according to the opinion of the vulgar hee accounteth that man foolish that wanteth braines. For the further confirmation of this opinion we wil adde an elegant argument out of *Philo*.

Galen.

VVheresoeuer the Kings Guard is there is the person of the King whome they doe guarde; but the guarde of the Soule, that is, all the organs and instruments of the Sences

Philo his argument.

are

are placed in the head as it were in a Citadell or Sconce; there therefore doth the ſoule keepe her Court, there is her reſidence of Eſtate. If therefore the ſenſatine faculty be placed in the braine, the intellectuall muſt be there alſo, becauſe as ſaith the Philoſopher the office of the Intellectuall faculty is to behold and contemplate the Phantaſmes or Images which by the ſenſes are repreſented vnto it. We reſolue and conclude therefore that the braine is the ſeate of all the Animall faculties as well Senſatiue as Principall.

QVEST. II. *Whether the Principall faculties haue diſtinct places in the Braine.*

What a principall faculty is.

SEeing therefore the Principall faculties are there: Imagination, Reaſon and Memory; and that their ſeate or habitation is reſolued to be the brain: let vs now enquire whether they haue diſtinct & particular manſions prouided for euery one of them. *Galen* in his booke *de Arte parua* defineth principall functions to be ſuch as yſſue onely from a principle: and in the ſecond *de locis affectis* he addeth. Which are accompliſhed by no other part as by an Orgā and Inſtrument. And yet more plainely in the 7. book *de placitis Hip. & Plat.* Which are only in the braine and thence doe proceed, not receiuing their operation from any other Organs of ſenſe or motion.

The opinion of the *Arabians* that they haue diſtinct ſeates.

The whole Schoole of the *Arabians* hath imagined certaine manſions in the braine, and aſsigneth to euery particular faculty a particular ſeate; and this is *Auicen* his opinion, *Fen.* 1 *primi, doctrina* 6, *Cap.* 5. As alſo *Auerrhoes* in his Canticles, his book *de memoria et reminiſcentia and in Colliget.*

They place therefore the Phantaſie in the forward ventricles, Reaſon in the middle, and Memory in the hinder ventricle: and this opinion may be eſtabliſhed by many arguments

The firſt argument.

on this manner. Almoſt all the ſences are placed in the forepart of the head, wherefore becauſe the Imagination is to receiue and apprehend the ſpecies and repreſentations of ſenſible things it muſt be placed in the fore-part.

By the Imagination the Intellectuall power is ſtirred vp and abſtracteth the Images of things from thoſe Imaginations, and therefore it muſt be ſcituated next vnto the Phanſie; and becauſe that is the moſt immediate Inſtrument of the reaſonable Soule, it was fitte it ſhould reſide in the ſafeſt and moſt honourable place which is the middeſt, that is, the third ventricle.

This Intellectuall faculty commendeth thoſe abſtracted formes of things vnto the Memory, which it layeth vp as it were in a Treaſury, and therefore the ſeate of the Memory muſt be in the hindmoſt and dryeſt part of the Braine which is the fourth ventricle.

The ſecond argument.

Againe, the Imagination being a conception of Images, and accompliſhed only by reception and ſimple apprehenſion, requireth the ſofter ſubſtance of the braine wherein ſuch ſenſation might be made. The Memory deſireth the harder ſubſtance of the braine that it might be able the longer to retaine thoſe Notions which it ſtoreth vp. Ratiotination is beſt pleaſed with a ſubſtance of a middle nature betwixt the ſofter and the harder. Now the forepart of the braine is the ſofter, the hindpart the harder, and the middeſt of a middle conſtitution; and therefore the Imagination is in the forward ventricles, Ratiotination in

The third argument.

the middle, and Memory in the hindmoſt.

Thirdly, that theſe principall faculties are diſcluded or ſeparated by their manſions theſe things doe demonſtrate; becauſe if one of them be offended yea or periſh vtterly, yet the other may remaine vntainted or vnaffected. For it oftentimes happens that the Imagination is vitiated and yet the Intellectuall faculty not at all depraued. For the confirmation of

Hiſtories.

this we haue many elegant Hiſtories in *Galen*, as in the third chapter of his booke *de Symtomatum differentijs* and the ſecond chapter of his fourth booke *de locis affectis*. *Theophylus* being otherwiſe able to diſcourſe very well, hadde yet an Imagination that there were Fidlers in the corner of his Chamber and continually cryed to haue them thruſt out. Another being Phreniticall lockt the doores of his Chamber to him and carried all the veſſels to the Windowes, where giuing euery veſſell his proper name he asked thoſe that paſſed by, whether they would command him to caſt them out. *Thucydides* reporteth that when the plague was ſo hot throughout all *Græcia* and *Peloponneſus* that many did ſo vtterly forget what they had knowne before, that they did not remember their Parents or familiar friends. In theſe men therefore onely the Memory was offended; in *Theophilus* onely the Imagination, and in him that was Phreniticall onely the Intellectuall faculty or vnderſtanding.

More-

Moreouer, vnlesse the principall faculties had seuerall seats, why were there diuers ventricles or cauities made in the braine? And why is one of them more noble then another, vnlesse it be because it is the seat of a more noble faculty. The 4. argument.

VVe will also adde an argument taken from the secrets of Phisiognomy. They that haue a large Nowle or backpart of the head are sayde to haue happy memories: but when the forepart and the forehead doth set outward, the Imagination is the stronger. On the contrary, those that want both these processes are euen by the common people esteemed foolish Idiots: and this is the Phylosophy of the Arabians concerning the seates of the faculties. The 5. argument.

Let vs now come vnto the Greek Family. *Galen* the Prince of this Sect conceiueth that the principall faculties are all established in one place, occupied about the same Images or Notions, do vse the same instrument, to wit, the brain; but their manner of working saith he is diuers. In the eight booke *de vsu partium*, vnder the name *ἡγεμονικὸν*, hee comprehendeth the three principall faculties and teacheth that they reside in the whole braine; and in the same booke he sayeth that the principall faculties haue their residence or residence not onely in the ventricles but also in the whole body of the braine. The opinon of *Galen* against the Arabians.

For to what other purpose should the substance of the braine haue beene made so large and ample. In his third Booke *de Placitis Hippocratis & Platonis*, hee sayeth, that if one of the ventricles be offended, all the principall faculties are therewith affected. And this is confirmed by daily experience and the euent of things. For in the *Epilepsie* or falling Sickenesse there is an interception of the minde and al the sences, and yet this obstruction doth not occupy all the ventricles. The Phrensie is an inflamation of the braine and his membranes. Now we obserue in this disease that sometimes Reason alone is peruerted, sometimes the Imaginatiõ, somtimes the Memory: yet who will euer say that in the phrẽsie one ventricle onely is inflamed? In that kinde of *melancholia* which proceedeth immediately from the braine and is a cold and dry distemper of the whole substance thereof, yet sometimes I say in that disease onely one faculty is depraued, sometimes the Reason sometimes the Imagination. VVherefore the principall faculties are diffused through all the ventricles and through the whole marrow of the braine. And though they are distinct one from the other, yet doe they exist together in the same particle of the subiect; for one and the same Soule performeth the offices of these different faculties by the vse of diuers meanes and a difference of Tempers. So in one and the same particle of a bone there are diuers faculties included, a drawing, a retayning, an assimulating and an expelling faculty. One of which, though it be affected when as oftentimes the rest are not taynted, yet a Physition will not therefore say that they are discluded in their seates and subiects. As therefore in the stomacke diuers faculties are offended by diuers distempers, the retayning faculty especially by a moyst distemper & the assimulating by a dry, yet are not these faculties separated in diuers partes of the stomacke: so with *Galen* wee thinke and determine concerning the principall faculties, that the whole substance of the braine is the seat of them all promiscuously disposed therein, which substance if it bee somewhat dry a man shall haue a faster Memory, if somewhat moyst his Imagination or fantasie will be the better. Authorities. Examples. Inference vpon the examples. Comparison

They that follow the opinion of the *Arabians* doe obiect vnto vs that *Galen* is on their side, for in his Booke *de oculis*, he placeth the Fantasie in the forepart of the brain, Reason in the middest, and Memory in the hinderpart. VVe answere that we thinke that Booke is not *Galens* but a bastard falsly fathered vpon him. They adde further that when the imagination is offended *Galen* applyed his remedies to the *sinciput* and forepart of the head; because there is the seate of the Fantasie. But they doe not consider that *Galen* doth the very same almost in all diseases of the head, as the *Caros*, the *Apoplexie*, the *Phrensie* & *Melancholia* in the twelfth of his Method and in the second Booke *de Medicamentis secundum locos*, and that not by the reason of the diuersity of seats, but that the force of the medicine might sooner penetrate into the inner parts of the brayne. For that which is applied to the forepart of the head pierceth deeper and sooner because of the thinnes of the skul in that place and the openesse of the Coronall suture. Obiection. Answere.

That place of *Galen* in the second Chapter of his fourth Booke *de locis affectis* seemeth to make more for their purpose, where he writeth. *If when the forepart of the braine is offended the third ventricle be affected by consent, then will the vnderstanding be depraued* Hee seemeth therfore to say that the vnderstanding is not vitiated vnlesse the third ventricle be offended. Againe, in the 27. Commentary vpon the first Section *Parrhet*: *If a humour bee setled and stablished in any part of the braine those symptomes will follow which are agreeable* A 3 obiection made. Places of *Gal.* for the Arabians.

as well to the nature of the part as to the humor, as for example. If the humor bee eſtabliſhed in the forepart it will breede a Phrenſie in which the Imagination is offended. Hee addeth further. *When the matter is tranſported in the Brayne out of one part into another, the diſeaſe will continew to be of the ſame kinde, but the ſymptoms will alter according to the part affected, as ſometimes the Imagination will be offended, ſometimes the Reaſon.* We anſwere, that we thinke all the principall faculties are contained in the whole braine, but we do not deny but that one faculty is more manifeſt in one ventricle then it is in another, as the ſpirits are in this cauity more thin, perfect and better laboured then they are in another.

Anſwere to thoſe places.

Obiection.

Finally they obiect, if the principall faculties be not ſeuered in their places and habitations, why is one ventricle more noble then another? For *Galen* in the 5. Chapter of his third booke *de locis affectis*, and in the 8. *de vſu partium* preferreth the hindmoſt ventricle to both the reſt and the middle to the foremoſt. And againe in the ſixt chapter of his ſeauenth booke *de placitis Hip. et Platonis*, he writeth, that the wounds of the fore ventricles are dangerous, of the middle more dangerous and of the hindmoſt moſt dangerous of al, which ſeemeth not to happen by reaſon of the ſtructure, temperament or ſubſtance of the braine, becauſe all theſe are in all places of the braine alike, but by reaſon of the faculties contained in the ventricles.

Anſwere.

Some anſwere that the third and fourth ventricles are more noble then the foreward, not becauſe there reſideth in theſe more noble faculties, but becauſe in them the Animall ſpirit attaineth a further perfection; ſo that by how much the Liuer is more noble then the ſtomacke, the heart then the Lungs and the left ventricle of the heart more excellent then the right, by ſo much and for the ſame reſpects the backward ventricles of the braine are more noble then the foreward.

The concluſion of the queſtion.

We conclude therefore with *Galen*: That all the principall faculties doe promiſcuouſly inhabite in the ſame part of the Braine together, that they vſe the like corporeall Inſtrument, that is, the ſubſtance of the braine, yet they worke after a diuerſe manner according to the variety of the Temperament and the *Medium*.

QVEST. III. *Whether the principall faculties doe depend vpon the Temperament of the braine or vpon the Conformation, that is, whether they be ſimilar or organicall actions.*

That the faculties proceede from the conformation.

IT is a moſt obſcure quæſtion whether the Braine do vſe reaſon and apprehend phantaſmes becauſe it is of ſuch a temper, or becauſe of the admirable ſtructure it hath. Some haue conceiued that theſe faculties are performed onely by the Conformation, which their opinion they confirme by authorities and by argumens. *Galen* writeth in his 7. Book *de placitis*, that the cauſe of wiſedome in man is the variety of the ſtructure of the Braine and the magnitude thereof. The figure of the head according to *Hippocrates* and *Galen* if it bee naturall, that is, ſphericall or round, ſomewhat long, bunching ſomewhat out before and behind and depreſſed or flatted on the ſides, is a ſigne of a wiſe man; and contrariwiſe a ſharpe and Turbinated head like a ſugar loafe, which they call σοφὸν ſuch as was *Thyrſites* head in *Homer*, is an argument of a dull or ſtollid foole. Againe, all the principall faculties periſh when the conformation or ſtructure is vitiated although the Temperament be not yet vitiated, as in the Apoplexy, the Epilepſie and in wounds of the head when the ventricles of the braine are eyther ſtuffed or compreſſed. For in the cracking of the Scull, how can the temperament of the braine in a moment be altered, or elſe in the oppletion or filling of the ventricles by any humor? It appeareth therefore that the principall functions are performed only by the ſtructure and conformation onely of the brain, and that conformation being vitiated they are preſently intercepted.

Authorities. The 1. reaſon.

The ſecond.

The contrary opinion.

On the contrary there are others who thinke that the next and immediate cauſe of theſe principall faculties is the temper of the marrowy ſubſtance and of the ſpirits of the braine. Let vs heere *Hippocrates*, *Apollos* eldeſt ſonne and the pillar of the family of Phyſitians in his firſt booke *de diæta* teaching the ſame thing in plaine words. *When in the body the dryeſt part that is the fier, and the moiſteſt part that is the water, are æqually tempred, then is a wiſe man borne.*

Authorities. *Hippocrates.*

Plato.

And theſe are the words of the diuine *Plato* in *Theateto*. *The ſoule is not well diſpoſed in a denſe or muddy brain, neyther yet in a ſoft or hard brain; for ſoftnes makes men of quicke apprehenſiõ but then they are forgetful withal, hardnes makes better memories but dulnes of capacity and*

and density containeth duskish and obscure phantasmes or images. *Galen* in his 8. booke *de vsu partium* sayth, *It is better to thinke that the vnderstanding followeth not the variety of composition, but a laudable Temper of that body wherewith we vnderstand: for the perfection of the vnderstanding is not so much to bee attributed to the quantity of the spirits as to the quality.* The same *Galen* in his Booke *de Arte parua*, referreth the causes of wit or capacity to the thicke or thin substance of the braine. *Galen.*

This wit hee calleth ἀγχίνοιαν, that is, *a working capacity*, which is defined εὐστοχία, that is, a promptitude or readines of Inuenting and coniecturing. In the same Booke εὐμάθεια, that is, a facility of learning sheweth a soft and moyst substance of the brain, and δυσμάθεια, that is a ineptitude to learne, a drie and a hard braine. Those that are light witted and inconstant in their opinions are for the most part of a hot braine, because heate is full of motion. But those that are obstinate are of a cold braine because cold is sluggish, to which if you adde drought then will such men become stubborne and refractary; and hence it is for the most part that the Authours and fautors or defenders of Schismes and Sects are Melancholy. *Galen* in his book intituled *That the maners of the mind follow the temperature of the body*, calleth the Soule *a consent of qualites*, & doth not distinguish it from the temperament

In his Commentary vpon the 6. Booke *Epidemion* and vpon the sixt Aphorisme of the second Section, as also in the 6. Chapter of his Booke *de locis affectis*, he styleth the Temperament of the braine *the Minde*. For so he expoundeth that Aphorisme of *Hippocrates*, Melancholy men become Epilepticall and Epileptical men Melancholy; as the humour ascendeth into this or that part so is there a transmutation made of these diseases. For if the humour be transfused into the body and ventricles of the braine then they become Epileptical, if into the minde they become Melancholicall; where-by *Mind* he vnderstandeth the Temperament. For the disease called *Melancholy* is a cold & dry distemper of the brain. But when *Galen* called the Soule a Temper, he doeth not conceiue that that Temper is the forme of a reasonable man, but the *forma medica*, because that onely falleth into the Physitions consideration. *Galen* calleth the Soule a temper. How & why.

For that which can neither bee preserued when it is present nor restored when it is absent, that doth not at all belong vnto the Physition: but the intellectuall Soule can neither bee preserued being present nor restored being absent; onely the Temperament may bee maintained when we haue it, or restored when it is lost. The Temperament therefore only is the Physicall forme of a man, because the Physition considereth a mans body not as it is Natural consisting of Matter and Forme, but as it is subiect to sickneſſe, and againe liable to Physicke. And from hence some men doe imagine that it is sufficiently prooued that the principall faculties of the Soule are not excercised by the structure or conformation but by the Temper of the braine.

Our opinion concerning this question is, that the efficient cause of all the functions is neither the Temper alone, nor only the wonderful structure of the braine; but the intellectuall Soule which notwithstanding admitteth both these causes: one Organicall which is the amplitude or largeneſſe of the braine and of the ventricles and the plenty of the spirits: the other Similar which is the Temper of the marrowy substance and of the spirites. From hence wee gather that *Ratitionation*, that is, the vse of Reason is neither absolutely an Organicall action because it is impaired in those that are Melancholicall and Phreniticall, when the structure of the braine is not at all violated; neither yet purely Similar, because the brain is offended when his ventricles are cõpressed or stuffed vp, all be the Temperament be not offended. What we resolue of.

Furthermore this *Ratiotiation* is neither inchoated nor perfected by the Temperament alone, neither yet performed by any particle of the braine, but is an action mixed or compounded of an organicall and Similar, such as is the action of the heart & the stomack. For the heart indeed is moued and hath his pulsation from an ingenite faculty and proper Temper of his owne: But it could neither haue been contracted nor distended vnleſſe it had beene excauated or hollowed into ventricles.

QVEST. IIII. *Of the vse of the Braine against Aristotle.*

IF euer that great interpreter and inesſenger of Nature *Aristotle* the Prince of the *Peripateticks* doe leſſe sufficiently acquite himselfe it is in the matter of Anatomy, & more especially in that he hath written concerning the vse of the brain in the seuenth Chapter of his second Booke *de part. Animal.* where he cannot be redeemed from palpable absurdity. The braine sayth he was onely made to refrigerate The vse of the braine after *Aristotle.*

the heart. First, because it is without blood and without veines; and againe because a mans braine is of all other creatures the largest for that his heart is the hottest. This opinion of *Aristotle*, *Galen* in his 8. booke *de vsu partium* confuteth by these arguments. First, seeing the braine is actually more hot then the most soultery ayre in Summer, how shall it refrigerate or coole the hart? Shall it not rather be contempered by the inspiration of ayre which it draweth in and as it were swalloweth from a full streame? If the *Peripateticks* shal say that the externall ayre is not sufficient to refrigerate the heart but that there is also required an inward bowell to assist it: I answere, that the braine is farre remoued from the heart and walled in on euery side with the bones of the Scull. But surely if Nature had intended it for that vse, she would eyther haue placed it in the Chest or at least not set so long a necke betweene them. The heele saith *Galen* hath more power to coole the heart then the braine: for when they are refrigerated or wet, the cold is presently communicated to the whole body, which hapneth not when men take cold on their heads. Beside, the braine is rather heated by the heart then the heart cooled by the braine, because from the heart and the vmbles about it, there continually arise very hot vapours, which beeing naturally light do ascend vpward. Adde hereto this strong Argument which vtterly subuerteth the opinion of *Aristotle* and the *Peripateticks*. If the braine had beene only made to coole the heart, what need had there bin of so admirable a structure? what vse is there of the 4. ventricles, the Chambered or Arched body, of the webs and textures of the Arteries, of the pyne-glandule, of the Tunnell, of the Testicles and Buttocks, of the spinal marrow and of the manifold propagations of the sinewes?

Aristotle confuted.

A very strong Argument.

Finally, if this were true that *Aristotle* affirmeth, then should the Lyon which is the hottest of all creatures (witnesse his continuall disposition to the Ague) haue had a larger braine then a man, and men because they are hotter should haue larger braines then woemen; which things because they abhorre from reason and sense, wee doubt not to affirme that the brain was created for more noble and diuine imployments then to refrigerate the heart. The body therefore of the braine was built for the performance of the Animall, Sensatiue, Motiue and Principall functions, and it is hollowed into so many ventricles & furnished with so many textures and complications of vessels; for the auoyding of his excrements, for the preparation and perfection of the Animall spirits; besides, the Nerues serue as Organs to lead out the same Animall spirit together with the faculties of motion and sense vnto the sences and the whole body. *Auerrhoes* (*Aristotles* Ape and where occasion is giuen a bitter detractor from Physitions) endeauoreth to excuse *Aristotle* and saith, That the braine doth therefore refrigerate the heart because it tempers the extreame heat of the vitall spirits. But let vs grant that the braine tempers some spirits, yet it will hardly temper the spirits of the heart & of the large Arteries, if it at all temper those spirits which are contained in the substance and membranes of the brain; which spirits so tempered seeing they do not returne vnto the heart, how shal they temper the heat of the heart? *Alexander Benedictus* in the 20. Chapter of his fourth booke seemeth to follow the opinion of *Auerrhoes*. *Albertus Magnus* a man better stored with learning then honesty, although hee be a *Peripatetick*, yet in this point he falleth from his Maister *Aristotle*, and saith in his 12 booke *de Animal.* that the braine by his frigidity doth no more temper the heat of the hart then the siccity or drinesse of the heart doth temper the moysture of the braine.

The true vse of the braine.

What *Auerrhoes* opinion is.

But confuted.

Whether the braine be the originall of the sinewes?
Whether the Nerues be continued with the veines and Arteries?
Whether the Nerues be the Organs of sense and motion?
Whether the Nerues of motion differ from the Nerues of sense?
Why the sense may perish, the motion being not hindered, or on the contrary?
Whether the faculty alone or a spirit therewith doe passe by the Nerues?
By which part of the Nerue the inner or the vtter, the spirit is deriued.

All these questions and difficulties with their resolutions you must seeke for in the third part of our booke of the vessels. The rest of the questions we now prosecute.

Where these questions are disputed.

QVEST.

QVEST. V. *VVhence it is, that when the right ſide of the Head or Brayne is wounded or enflamed, a Convulſion falleth into the oppoſite partes.*

WEe haue a double Probleme heere to diſcuſſe. The firſt, how it commeth to paſſe, that when the right ſide of the Head is wounded or enflamed, it oftentimes falleth out that the lefte parts of the bodie ſuffer Convulſion. The ſecond, why one part of the Braine beeing ſmitten or obſtructed, it ſometimes happeneth that the contrary ſide of the body is reſolued or becommeth Paralyticall.

Both theſe queſtions haue in them many difficulties. For the affections or diſeaſes almoſt of all the parts are communicated κατ' ἰξιν, that is, *by rectitude*, not ἀνάπαλιν, that is, *by Contrariety*, becauſe the right ſide with the right and the left with the left are ὁμόφυλα, that is, *haue a ſimilitude of ſubſtance*. And therefore when the Spleene is affected the left ſide is pained and when the Liuer is offended the right. And in the ſecond Section of the ſixt Booke *Epidemiã*. The paines of the ſides, as Pleuriſies and ſuch like are *è directo*, that is on the ſame ſide; ſo alſo is the Tenſion or ſwelling of the *Hypochondria*, the tumor of the ſpleene and the bleeding at the noſe. Wee will firſt therefore entreate of Convulſion and then of the Palſie.

The affectiõs of the partes are communicated accor ding to *Rectitude*,

That the oppoſite partes are conuelled *Hip.* authority

That the oppoſite parts ſuffer Convulſion *Hippocrates* firſt of all men taught vs in his Booke *De vulneribus Capitis*. By oppoſite parts he vnderſtandeth ſometimes of the head alone, ſometimes of the whole body. Of the Head alone, whereas he writeth that the Veines which run through the Temples are not to be opened, becauſe there is daunger of Convulſion, of the right ſide if the left Veine be opened, and on the contrary.

Many Hiſtories.

Of that convulſion which affecteth the reſt of the parts of the body, he maketh mention in the ſame Booke. *If* (ſaith hee) *the Bone be purulent, then will Puſtles ariſe in the tongue, then the patient wounded will dye idle-headed, and for the moſt part the other ſide of his body ſuffereth Convulſion, for if the right ſide of the head be wounded then will the Convulſion occupy the left parts of the body, and on the contrary.*

In the fift Booke *Epidemiõ* he telleth of a wench whom he calleth *Puella Omilæa*, who had a bruiſe on the right ſide of her head in the middle of Summer and ſuffered convulſion onthe left parts. *Antoninus* had both his hands conuelled when he was ſtricken with a ſtone in the middle of the *ſynciput* or fore-part of the head about the mold.

Two thinges gathered out of *Hippocrates*.

In the ſeuenth *Epidemiõ*. In the Hiſtory of the ſonnes of *Phanius* and *Euergus* who were wounded in their heads. *In ſuch* (ſaith hee) *it happeneth that they fall to vomiting and ſuffer Convulſions, and that in the left parts if the right ſide be wounded, and in the right if the left.* Wherefore I gather out of *Hippocrates* theſe two things. Firſt, that Convulſion doth not alwayes follow, but onely when there is ſuppuration made, or whilſt it is ſuppurating, or when there is a great inflamation. Againe, that all that are wounded doe not ſuffer Convulſion but the moſt, ſo that it it not perpetually or vniuerſally true, that if one part be wounded, the contrarie part is conuelled.

Why one temporall Muſcle is conuelled when the other is wounded.

To aſsigne the cauſe of the firſt Convulſion it is not hard; for if the right temporall Muſcle be wounded or reſolued, yet doth not a Convulſion properly ſo called *primarily and of it ſelfe* fall vpon the oppoſite Muſcle, *but onely by euent*, becauſe all the Muſcles are either *Antagoniſts* that is aduerſary, or *Congeneres* that is a *Kin*: if they bee *Congeneres* then the reſolution or ſection of one cauſeth the Convulſion of the other: but if they be contrarie or aduerſary ſo that their motions ſuccede one the other, then one of them periſhing the other is neceſſarily taken away. For if the muſcle which extendeth a part bee cut, the part will indeede be bent, but it will ſo alwaies remaine, becauſe it can no more be extended, and ſo the Convulſion is accidentary and improperly ſo called.

The cauſe of oppoſite convulſion is a malignant quality.

But the Nature of the other convulſion which is of the reſt of the parts of the body not of the head alone, is much more obſcure, notwithſtanding *Hippocrates* in the places before quoted ſeemeth to acknowledge the cauſe to bee the malignity of the *pus* or matter, which launcing the Membranes which are of an exquiſite ſenſe and pricking the originall of the ſinnewes ſtirreth vp a depraued motion. Now there paſſeth from the wounded part into the ſound part ſometimes a breath alone, ſomtimes a portion of the malignant *Ichor* or humor. The breath vapoureth away thorough inſenſible paſſages, but how the *Ichor* or thin humor ſhoulde paſſe from the wounded part to the oppoſite ſide it is not eaſy to declare.

How the Ichor is carried out of the ſound part into the offended.

It muſt needs be either tranſmitted, or muſt fall downe, or be Propagated or finally Expreſſed. No man will ſay it is tranſmitted out of the wounded part into the ſound, becauſe the weaker part doth not vſe to exonerate it ſelfe into the ſtrõger; neither doth it fall down becauſe all ſuch ſinking downward is perpendicular, that is, directly downeward, for it followeth the motion of the humour, which motion ſeeing it dependeth vpon the Elementary form, as Philoſophers conclude it muſt be right and ſimple: wherefore it is either propagated or expreſſed, and both theſe I heere acknowledge. It is propagated if it abound in quantity, if the ſubſtance of it be very thin, if the quality bee very ſharpe: ſo Choler which is of Temper exceeding hot and raging when it breedeth an *Eriſipylas* or Saint Anthonies fire in the inward parts, diffuſeth it ſelfe ſometimes euen to the outward parts alſo. So ſaith *Hippocrates* in a Squinſey of the *Larynx* or throttle, both the neck and top of the Cheſt are very red, *per ἐπιγνωσιν*, that is, by conſequence or ſucceſsion. What therfore ſhal hinder the diffuſion of a thin Ichor through the whole membrane if the inflamation bee come to his height? But if there be not that plenty of Ichor that it can be propagated, yet may there be made an Expreſſion of it out of the right ſide into the left; and often there is from lower partes to the vpward a *θλῖψις*, that is, a Compreſsion. Nowe Expreſsion is made by compreſsion, Compreſsion by ſuppuration, which whileſt it is a making doeth diſtend the neighbour parts, becauſe the woorking or boyling humour occupieth a greater place; and hence come paines and Agues in the time whileſt the *Pus* or Matter is in confecting, and therefore *Hippocrates* ſayeth that convulſion is eſpecially then induced when ſuppuration is a making.

Inſtances.

Hippocrates

Puella Omiſea.

In *Puella Omiſea* it is likely that the Ichor was not diffuſed, but expreſſed out of the wounded part into the part oppoſite. It may happen that a very little as it were a droppe of the Ichor may moue a convulſion, as alſo a venomous vapour, by goading the membranes of the nerues which are of moſt exquiſite ſence. VVherefore the humour which breedeth the convulſion is oftentimes expreſſed or propagated from the diſeaſed into the ſound part, neither is it neceſſary alwaies that an Ichor ſhould be expreſſed or propagated it is ſufficient if a malignant ayre breath out of it.

Two obſcure queſtions.

But here we obſerue two things very obſcure and intangled. Firſt, how the Ichor can paſſe out of the wounded ſide into the contrary, ſeeing that the braine is diſtinguiſhed into the right ſide and the left by a proper midriffe of his owne and that exceeding thick, which is a duplication of the *Dura Meninx* called the Sythe, becauſe it is like a Mowing Sythe or Siccle? The other why when as the ſame Acrimony of the *Pus* or quitture pricketh the Membrane of the wounded part, it doth not ſtir vp convulſion in the ſame but in the oppoſite part.

How the Ichor paſſeth into the oppoſite part.

The diſſolution of the former is fetched from Anatomy. The hard membrane which toucheth the Skull in the vpper and *exterior* part is wholly continuated and lined as it were or ſmeared ouer with a watry humour; betwixt it and the bone of the Skull is the purulent matter gathered, which may be both Expreſſed and Propagated out of the right ſide into the lefte by the continuity of the membrane, and furthered by the orbicular figure of the head.

A ſmall portion of the Ichor expreſſed out of the affected into the ſound ſide, ſometimes by reaſon of the tenuity ſweateth through the membranes into the marrow of the braine, and out of it into the nerues; whence comes their inflamation: ſometimes by the outſide of the membranes it falleth into the ſpinal marrow which is inueſted with the ſame membrane, where goading the originall of the nerues it procureth a convulſion by ſympathy or conſent, ſo that when the membranes are vellicated or enflamed a convulſion ſooner enſueth then if the internall or marrowey ſubſtance of the nerues were affected.

But why is the convulſion not in the wounded but in the oppoſite part? It is obſerued that ſometimes when the right ſide of the head is wounded the right parts of the body are alſo conuelled, ſometimes the oppoſite parts onely, oftentimes both together *When* (ſaith *Galen*) *the Inflamation toucheth the originall.* It is not therefore perpetually true, that when one part of the head is wounded the oppoſite part is conuelled, but becauſe it hapneth ſo for the moſt part, let vs enquire the reaſon thereof.

Why the woũded part is not conuelled

The convulſion is in the oppoſite not in the wounded part, becauſe the purulent matter which is expreſſed or diffuſed out of the wounded into the ſound part hath no iſſue but is there ſtabled or gathered and breedeth an inflamation; and from thence comes the convulſion: but the *ſaries* or *Matter* which gathereth in the wounded part hath free egreſſe by the

the wound and by the ſection of the bone, and ſo the Membrane is not affected. And this haply *Hippocrates* meaneth when in the hiſtory of the wench he ſaide, that the left parts ſuffered convulſion becauſe the contuſion was on the right ſide. VVe may alſo aſsigne another reaſon of this convulſion and that very probable. The wounded part is not conuelled but the oppoſite, becauſe the faculty of the wounded part is extinguiſhed and diſſolued, and the temperament which is the cauſe of all actions is notably depraued; wherefore though the faculty be prouoked yet it anſwereth not, neyther doth any motion follow ſuch prouocation. *Hippocrates.* Another reaſon of it.

Now that vpon a ſuppuration or notable inflamation the part is almoſt mortified *Hippoc.* is witneſſe in his book *de vulneribus Capitis*: but the oppoſite part hauing a quick ſenſe is preſently contracted & draweth into conſent with it all the nerues of the ſame ſide; and ſo convulſion followeth κάλιξιν by *a rectitude of veſſels.* And this our coniecture the place of *Hippocrates* aboue named maketh good. For when the convulſion falleth vpon the oppoſite part then the caſe is deſperate, puſtules ariſe in the tongue, and the patient dyeth in a *deltrium* or light phrenſie. *Hippocrates.* *Hippocrates.*

QVEST. VI. *Why when the right ſide of the head is wounded or obſtructed the oppoſite part is reſolued or becommeth Paralytical.*

COncerning the Palſy the difficuly is greter, the knot harder to cleaue namely, why when one part of the head is wounded or one of the vẽtricles of the braine obſtructed or compreſſed, the oppoſite parts are reſolued or become Paralyticall? That it is moſt true the examples are infinite, and all Phyſitions both ancient and moderne in their writings do agree vpon it. *Hippocrates* maketh mention of this kinde of Palſie in his booke *de vulneribus capitis* and *in Coacis prænotionibus. Thoſe* (ſaith he) *that becom impotent of wounds in their head do recouer if an Ague without horrour ouertake them, otherwiſe they become apoplecticall in the right parts or in the left.* That is paralyticall. For *Hippocrates* often ſaith *Crus apoplecticum* for the leg taken with the Palſie. In the hiſtory of the ſonnes of *Phanius and Euergus* in his 7. booke *Epidemion* hee writeth that they become *impotent (if the wound be in the right part) on the left ſide, and on the right ſide if the wound were on the left part.* *Aretæus* in the 7. chapter of his firſt booke *de Cauſis et ſigmis diuturnorum morborum* is of the ſame minde. *If* (ſaith he) *the head be wounded at firſt on the right part the left ſide is reſolued; if on the left the right ſide.* Salicetus ſetteth this down for a Catholike or vniuerſall Theoreme *or Maxime. Whenſoeuer any man is wounded in the head ſo that a Palſie happen thereupon, if the wound be in the right part of the head the left ſide will be paralytical and contrariwiſe.* The ſame hath *Iohannes de Vigo* obſerued: and *Hollerius* in his Commentaries *in Coacas prænotiones Hippocratis.* And wee alſo ſaith *Laurentius* our Author, haue obſerued the ſame. That the oppoſite parts are reſolued, prooued by authorities. A hiſtory out of *Hippocrates.* Diuers opinions how this Palſie commeth.

Wherefore that it is ſo, there is no controuerſie; all the queſtion is, *why and how* it commeth ſo to paſſe, and that indeed is much diſputed. Some imagine that the nerues in their originall are ſo implicated that the right nerues run along the left ſide and the left along the right ſide, interſecting themſelues in manner of a S. *Andrewes* Croſſe, which interſection is called χιασμὸς and therfore it is, ſay they, that when the right part is obſtructed or otherwiſe affected the left ſide is conuelled or reſolued and on the contrary, becauſe the originall is affected. And this is the opinion of *Caſsius* and *Aretæus*. *Caſsius* thought that the nerues do ſo take their originall from the Baſis of the Braine, that thoſe which aroſe from the right part were carried into the left, and thoſe which aroſe from the left ſide into the right, croſsing one another ouerthwart. *Aretæus* is of the ſame opinion. The right nerues, ſaith he. do not proceede directly into the right parts vnto their terminations; but as ſoone as they ſpring vp they cut ouer to the other ſide croſsing one another like the letter X which the *Græcians* call χιασμὸν. But the leuity of this opinion needeth no confutation. For ocular inſpection which wee call αὐλοψία teacheth vs that all the nerues which ariſe out of the marrow of the braine are altogether diſtinguiſhed and ſeperated in their originall, progreſſe and inſertion; excepting onely the opticks which in the middle of their iourney do meet & that neceſſarily, that they might paſſe directly to the apple of the eye; that they might not grow flaccid or looſe in their long iournybeing very ſoft; that the ſimple & ſingle obiect of the eye might not ſeeme double: and finally, that the formes and images of viſible things might be vnited. Onely therefore the opticke nerues do meet, The firſt. Of *Caſsius* and *Aretæus* that the nerues croſſe one another. Confuted. χιασμὸς. None but the opticks doe interſect.

yet

yet ſo that they neuer interſect or croſſe one the other. VVee haue alſo of late obſerued, ſaith *Laurentius*, that the nerues of the ſecond coniugation haue beene continuall in their originall.

As for the nerues of the ſpinall marrow, the right are ſeparated from the left, neuer cutting one ouerthwart another. It is therefore abſurd to referre the cauſe of the convulſion and Palſie which happeth on the aduerſe ſide to the interſection of the nerues & their Croſſe permutation as *Aretaus* would haue it, becauſe it is a meere fable.

The 2. opinion that the ſpirits paſſe by the arteries which interſect.

Some conceiue that not the nerues, but the veines and ſmall arteries of the braine are implicated firſt in the baſis of the braine, then in thoſe two labarynthian textures, the one called *Choroides*, the other *Rete mirabile*, ſo that they are diuaricated out of the right ſide into the left, and out of the left ſide into the right. They thinke therefore that when the ventricle on the right ſide of the braine and the parts therof are obſtructed or compreſſed, the left ſide is conuelled or reſolued becauſe the entercourſe of the ſpirites is intercepted by the oppreſsion or obſtruction of their common fountaine, and at length by ſtopping of the way of the ſpirit which they perſwade themſelues is communicated to the whole body by the arteries not by the marrowey and inward ſubſtance of the nerues. I cannot but acknowledge this conceite to bee very ingenuous and ſeemingly true if it were not that it is contradicted by the principles of Anatomy. For to winde vp the matter in a few words, this opinion taketh theſe two poſitions for good. Firſt, that the veſſels doe interſect or croſſe one another, and againe that the Animall ſpirites are conuayed by veſſelles not by the marrow of the nerues; which, how diſſonant they are from the trueth may thus be demonſtrated by the two common and moſt competent iudges of all Controuerſies, reaſon and ſence.

Confuted.

The diuarication of the veſſels of the braine.

All the veſſels which irrigate or water the whole body of the braine and his membranes are propagated from the internall Iugular veine and from the arteries called *Carotides* and *Cernicales*: now we are taught by αὐλοψία or ocular inſpection, that the diuarication of theſe is on this manner.

The right *Iugular* veine powreth the bloud into the right *ſinus* of the *dura mater* as it were into a Ciſterne, and the left into the left; out of the συνδρομῆ or *Concourſe* of theſe two ariſeth the third *ſinus*, which running through the length of the ſagittall ſuture is conuayed to the top of the noſe, and from this many ſmall veines are diuerſly diſperſed into the *pia mater*: the fourth *ſinus* concaued between the Braine and the After-brain determineth at the buttocks of the Braine.

The *ſinus* or duplication of the *dura meninx*.

Theſe *ſinus* as it were riuerets ſubſtituted by Nature inſtead of veſſels, doe diſperſe the bloud on al hands, and from them as out of a preſſe, the bloud ariving vnto them from the *Iugular* veines, is expreſſed into the whole body of the Braine. The *Iugular* veines therefore doe meete and vnite themſelues in the third and fourth *ſinus* of the *dura mater*, but yet are neuer ſo implicated that the right doe paſſe vnto the left ſide, or the left vnto the right; there is no interſection of theſe veſſels no χιασμὸς. Neither is there any interſection of the right *Carotidall* or *ſleepy arteries* with the left, becauſe they doe not power vitall ſpirits into thoſe *ſinus* or duplications of the membrane as the veines doe the bloud, neyther are the right implicated with the left, but each artery maketh his owne texture, the right artery the right texture and the left the left.

The arteries of the brayne do not interſect.

Theſe textures or complications which are manifeſt in the vpper ventricles and called *Plexus Choroides* doe neuer ſo interſect themſelues that the right ſhould paſſe vnto the left, the left vnto the right parts, for the vpper ventricles are diſſeuered by their proper wall or diſtinction.

And if they ſay that the *Carotides* are implicated in the Baſis of the braine at the ſides of the buttockes and there interſect themſelues. I will indeede confeſſe that the arteries of the ſame ſide are implicated, that is, are contorted manifould like the tendrilles of a Vine crumpled vp together for the better preparation of the ſpirits: but that they interſect themſelues and from the right ſide paſſe vnto the left, that I conſtantly deny. For the holes of the buttocks do ſtand off one from the other, through which the arteries aſcend to the Baſis of the braine, and from them καθ' ἕξιν or by a right line to the vpper ventricles: which he that will not otherwiſe beleeue may thus proue by his owne experiẽce. Put a hollow Probe of Bugle into the right *ſleepy* arterie and blow it, and you ſhall perceiue that the arteries of the right ſide will be diſtended more then the arteries of the left. Let vs therefore cleare our conceites of this miſt and cloud of errour concerning the interſection of the veſſelles

Experience.

which

which *Autopſie* it ſelfe conuinceth to be a forged conceite.

Beſide experience we haue good reaſon alſo againſt it: for if we admit this interſe- Reaſon.
ction of the veſſels, then it wil neceſſarily followe, that whenſoeuer the right partes are ſtuffed or compreſſed the left parts ſhalbe reſolued; becauſe the courſe of the ſpirit is intercepted. But wee finde it often to fall out, that when the right Ventricle is obſtructed the parts of the ſame ſide are reſolued. But let vs for diſputation ſake admit (though wee do not grant it) that thoſe ſmal arteries and complications of them do interſect one another, muſt it thervpon needes follow that when the veſſelles are compreſſed the Palſye ſhould ſeize vppon the contrary ſide? The arteries are onely conceptacles of the Vitall ſpirits. Thoſe Vital ſpirits do onely conferre their helpe to the cheriſhing, rowzing vp, and reſtoring of the in-bred heate of the particular parts, but affoord no helpe at all to motion or ſenſe. Now in the palſy the part liueth though the Motion and Senſe be both of them quite intercepted. Wherefore by the Arteries the Animal ſpirit is not conueyed which is the author of all ſenſe and motion. The Arteries do not conuey the Animall ſpirits.

I know well that when the Iugular Veines and the Carotidall arteries are obſtructed, the *Caros* Apoplexy and Lethargie do follow; whēce the Carotidal Artery is called *Lethargical* and *Apoplectical*, and *Hippocrates* vſeth to call that kinde of Apoplexie, τὴν διὰ τῶν φλεβῶν ἀπόληψιν, *the interception of the Veynes*: but this Apoplexie hapneth but by accident and is cureable, wherein acceſſe is denied to the vitall ſpirite which miniſtereth matter to the Animall. But the Queſtion in this place is of a true Palſy which happeneth vpon the exolution, madefaction, and (that I may vſe the Arabians word) Mollification of the Nerues, or when the wayes of the Animall ſpirits are ſhut vppe or intercepted. Theſe wayes are the Nerues, which albeit they haue no conſpicuous cauity, yet is their inward ſubſtance altogether ſpongie, through which the Animal faculty and thoſe impetuous ſpirits which *Hippocrates* calleth τὰ ἐνορμοῦντα do eaſily finde their way. A light kinde of Apoplexie whence.

Many learned men there are, who will not admit of this trueth, and eſpeciallie among the late writers *Rondeletius* ſtriueth to prooue that the Animal ſpirit is conueyed through the Arteries not through the marrowy ſubſtance of the Nerues: the onely vſe of the Marrow he acknowledgeth to bee, that like ſtockes it may ſuſtaine and ſtrengthen the ſmal and ſlender veſſels. *Argenterius* alſo thinketh that the ſpirits neuer forſake the Arteries. *Rondeletius* opinion that the Animall ſpirits paſſed through the Arteries.

It was an old opinion of *Praxagoras* as *Galen* remembreth in the 7. chapter of his firſt Booke *De Placitis Hippocratis & Platonis*, that the Nerues were continuated with the Arteries, and that the Nerues were nothing elſe but Arteries become now ſlender and ſmal. But the weaknes and inſufficiency of this opinion is hence conuinced, becauſe the intercoſtal Arteries are ſmal & threddy, & the arteries of the brain which make the two textures therof as fine as haires, and yet no man euer durſt call them Sinews. But of this we ſhall haue better occaſion to diſpute in our booke of the veſſels. In this place it ſhal be ſufficient to haue ſaide that the Animal ſpirits cannot paſſe by the Arteries becauſe they were deſtined and ordained by Nature for the tranſportation of the Vital ſpirites: now two ſpirits diſtinct in *forme* and *kinde* as we vſe to ſay, cannot be conueyed by the ſame Veſſels. When the Opticke Nerue is obſtructed the action of the ſight periſheth, are there then any ſmall Arteries intercepted? Or is their interception the cauſe of blindneſſe? Nothing leſſe, for the part ſhould be vtterly extinguiſhed if it wer no more illuſtrated with the beames of the Vital ſpirits. Wherefore when the marrowy ſubſtance is affected, when the ſpondils or rack-bones are luxated the body is often reſolued, becauſe the Marrow of the Nerue is preſſed, by reaſon of which compreſsion the paſſage of the animal ſpirit is intercluded. *Praxagoras* opinion out of *Galen*. Confuted. That the Animall ſpirites paſſe not by the Arteries. Diuers Argaments.

In thoſe that are afflicted with the Stone, the legge on the ſame ſide becommeth ſtupified, the Nerues and Muſcles which are ordained to bend it being compreſſed by the Kidnie lying therevpon. As for thoſe ſmal Arteries which run thorough the Membranes that couer the nerues they miniſter the ſpirit of life vnto the Nerues, not the faculty of Senſe and Motion. Againe, the Arteries of the braine do not eſſentially differ from other arteries, but other where the Arteries neyther engender nor conteine Animall ſpirits, therefore not in the braine.

Add hereto, that the forme of euery thing is ſtamped vpon the aliment and the ſpirit, onely by the ſubſtance of the part: now in thoſe complications there is onelie a power to prepare and as it were to delineate the ſpirites, their forme they haue onely from

from the Marrowy substance of the braine. Finally, as the Braine by reason of this marrowy substance is called the braine, and this marrow is the principal part of this noble Organ the seate of the Memory, Reason and Discourse: so I thinke that the chiefe part of the nerue is the marrow thereof, which carrieth the commaundement of the Sensatiue and Motiue Faculty, not onely by irradiation but by a corporeal spirit. And therefore it is that *Galen* in his eight Booke *de vsu partium* calleth the braine *Nervum amplissimum & molissimum, A soft and large Nerue*; and againe he calleth a nerue *Cerebrum durius & resiccatum, A hard and dryed Braine*. But if (as *Rondeletius* conceited) the inwarde part of the nerue hadde beene onely ordained for the establishing and sustaining of the final Arteries ioyned to their Membranes, then certainely is the Marrowye part of the nerue the baseſt and most ignoble.

Let therefore the opinion of *Galen* and of the Ancients remaine with vs as current and Cannonicall, to wit, that the Animall spirits passe through the marrow of the nerues not through the Arteries.

The cause of the palsie in the opposite part.

These things being thus established, it remaineth that we discouer the cause of the palsie which happeneth on the contrary side to the wounded or affected part. When the right part of the Head is wounded a portion of the *Ichor* may fall κατ' ἰξὶν *by Rectitude* into the right fore ventricle; now out of it into the third (which is common) there is a manifest passage, (this Ventricle *Galen* calleth the middle either because it is in the very center of the Braine, or else because it is scituated betwixt the two vppermost and the fourth Ventricle which is the lowest) and the humour conteyned in that Ventricle is as it were in the center of the Braine. Wherefore if it follow the Motion of the Elementary forme it must fall into a lower place: now the sound part is alwayes the lower, because the patient euer leaneth or lyeth vpon the sound side not vpon the sore side for auoyding of paine. What therefore should hinder but that the humour may fall out of the thirde ventricle into the fourth, and from thence into the spinall marrowe on the opposite part vnto that which is wounded, and so that part become Paralyticall or resolued? The Braine is not as some haue dreampt diuided from the top to the very bottome; the vpper Ventricles determine into a common cauity into which they thrust downe their superfluities. This common cauity is directed into the fourth Ventricle which is common both to the After-braine and the spinall Marrow. It is not therefore against our Anatomicall Principles or grounds, that *Matter, Flegme and Blood* may be transmitted from the right Ventricle to the thirde, and from hence through the fourth Ventricle into diuers parts of the spinal marrow, now into the right side and now into the left, as either of them is lower or weaker.

Another reason.

Another reason also may be brought of the palsy in the sound part not in the affected, because Nature vseth to auoyd the excrementitious humour by the wound, as sometimes by a flux of blood, somtimes by quitture, sometimes by Medicines which draw away and exhaust the humour either sensibly or insensibly, so that the affected part is well purged by some or more of these meanes; but the opposite part which is not expurged is easily affected either by simpathy or when the matter is transmitted or falleth vpon it.

Another.

Some thinke that almost all the spirits do flow to the part wherein the tumor or inflamation is, whence it is that the opposite part being defrauded of them is resolued.

QVEST. VII. *VVhat is the Nature of the animall spirit, what is the manner of his generation and the place thereof.*

WEe haue sufficiently prooued by strong Arguments that to Motion & Sense is required not onely an influence of a Faculty but also of a corporeall spirit. Now what name we shall giue this spirit, what his nature is, what is the manner and place of his generation we will breefely declare.

What is the animall spirit *Galen*.

Galen calleth this spirit euery where *Animalem* the Animall spirit, because the Soule vseth it as her immediate Organ for the performance of all the animall functions of sense and motion and those which we commonly call Principall.

This spirit in the 17. chapter of his sixt Booke *de Vsu partium* he defineth to bee an exhalation of pure blood. Some thinke it to be a part of the liuing Braine, yea both a Similar and an Organicall part: Similar as it hath a certaine and designed temper, Organical as it is thin, lucid, subtile, pure and moouable.

This Spirit some haue thought doth not differ in kinde and nature from the Vital but onely in accidents, as in temperament, place, the originall *à quo*, and the manner of diffusion.

ſion. For the Animall ſpirit is moyſter and more temperate, the Vitall hotter. The Animall commeth from the braine, the Vitall from the heart; the Animall is diſperſed through the nerues for Motion and Sence; the Vital through the arteries to maintayne the life.

We are of opinion that theſe two ſpirits are of a diuerſe forme and kinde, as Chylification is diuers from Sanguification. For the Organs are diuers, the faculties diuers, diuers is the manner of Generation: and as the Aliment by a new concoction receiueth a newe forme and ſo a new denomination, ſo is it with the ſpirits. *Galen* in a thouſand places diſtinguiſheth this Animall from the Vitall ſpirit, whatſoeuer ſome new Writers ſay to the contrary. In the 5. Chapter of the 12. Booke of his Method. *The Animal ſpirit* (ſayth he) *ariſeth out of the Braine as out of his fountaine.* The vital and animal ſpirits differ in form & kinde.

The demonſtration of the Vitall ſpirit is not euident, but yet it is agreeable to reaſon that it is contayned in the heart and the arteries. And if there be any Naturall ſpirit that is included in the Liuer and the veines. In the 7. Chap of his 3. Book *de locis affectis Gal.* ſaith, *The Epilepſie* hapneth in the braine when the humour hindreth the Animall ſpirit which is contayned in the ventricles thereof that it cannot haue yſſue out. In the 10. Chapter of his 16. Booke *de vſu partium*. The complications of the arteries doe nouriſh the Animall ſpirit contayned in the braine, which differeth much in Nature from other ſpirits. In the third Chapter of his 7. Booke *de placitis Hip. & Plat.* The ſpirit which is contayned in the arteries is indeed Vitall and ſo is alſo called; that which is contayned in the braine is Animall, not that it is the ſubſtance of the Soule, but becauſe it is the Soules firſt and moſt immediate inſtrument. The ſame alſo he writeth in the 4. Chapter of his 9. Book *de vſu partium*, In the 8. Chapter of the 9. Booke *de placitis Hip. & Plat.*, and in the 5. Chapter of the ninth Booke *de vtilitate reſpirationis*. Diuers places in *Galen.*

By all which places we may gather that *Galen* made a difference betweene the Vitall and the Animall ſpirits. And truely that there ſhould be an Animall ſpirit it was very neceſſary; firſt to conuay vnto the partes the facultie of Motion and Senſe which is not fixed in them; and againe that we might be more apprehenſiue of outward accidents. For ſeeing that the Organs of the Sences ought to be affected on the ſudden by ſenſible things, it was fit they ſhould not be altogether ſolide, but houed and fulfilled with ſpirits that they might the ſooner be altered. Moreouer theſe ſpirites doe transferre the *ſpecies* or formes of all outward things perceiued by the outward Sēces vnto the brain as vnto a Cenſor or Iudge. The ſame ſpirits doe conceiue in the braine the images of thoſe outward thinges, ſo that the Animall ſpirit may bee called the place and promptuarie of the *ſpecies* or formes. So in the *Vertigo* or Giddineſſe neither the thing it ſelfe, nor the Image of it, nor any thing beſide the ſpirit is rowled about, and yet notwithſtanding all things ſeeme to him that is ſo affected to runne round. VVherefore this ſpirite is neceſſary both for motion and ſence. As for the principal faculties; to the performance of all their functions the braine vſeth the miniſtery and helpe of this ſpirit; ſo that it worketh both within the braine and without the braine: within the braine it helpeth the principall faculties; without the braine it conferreth Motion and Sence. Nowe it is not onely abiding in the ventricles but alſo in the pores and in the whole marrowy ſubſtance of the braine, ſo that in the pores and ſubſtance it is communicated to the principall faculties: In the ventricles it ſerueth more immediately for Sence and Motion. The neceſſity & vſe of the animall ſpirit. The nature of the *Vertigo*.

Furthermore this ſpirit which is the immediate Organ of Sence and Motion and of the principall faculties, is indeede of one kinde notwithſtanding it is eſteemed manifould according to the variety of the obiects and inſtruments where about it is imployed: which thing *Ariſtotle* elegantly hath taught vs in the laſt chapter of his 5. booke *de generatione Animalium*. How the animall ſpirit is manifold.

The ſpirit ſayth he in Naturall things is like the hammer in the Art of the Smith, that is to ſay, but one inſtrument, yet profitable for the performance of many offices. *Actuarius* compareth it to the beames of the Sunne, which though they bee all of one kinde yet they become vnlike when they light vpon different colours.

It remayneth now that we ſhould manifeſt vnto you the Matter of the Animall ſpirit, and the manner of his generation. The matter of the animall ſpirit.

The matter of it is double, Ayre and the Vitall ſpirit.

The Ayre is drawne in by the noſethrils; the Vitall ſpirites are conuayed through the Arteries called *Carotides* and *Ceruicales* into the Baſis of the braine. VVith this Ayre the ſpirit is nouriſhed, and therefore *Galen* acknowledgeth a double vſe of Reſpiration, to witte, the con-

conſeruation of Naturall heate and the Nutrition or Generation of the Animall ſpirites. Now if the paſſage of theſe two matters to the braine be intercepted, then will there be no generation of Animall ſpirits. If the *ſleepy* arteries be bound an *Apoplexy* enſueth, if Reſpiration bee prohibited the Creature dyeth inſtantly and is depriued of Sence and Motion.

Galen concerning this poynt ſeemeth to differ from himſelfe, but we will reconcile thoſe different places well enough. In the 5. Chapter of his booke *de vſu Reſpirationis* he ſayth, that in a liuing creature he tyed the Sleepy Arteries and yet the creature periſhed not: therefore it followeth his Animall ſpirit was nouriſhed onely with Ayre not with the vitall ſpirit. In his third booke *de placitis* and in the 9 booke *de vſu partium*, hee writeth that the Animall ſpirit may bee cheriſhed and ſuſtained with the vitall conueighed by the Arteries and maketh no mention at al of the Ayer.

Certaine places of *Galen* concerning the Animall ſpirit reconciled.

Wee anſwere, that the Animall ſpirit may be for a little time ſuſtained if it be depriued of eyther of his Aliments: for there is ſtored vp a ſupply againſt time of need in thoſe two complications or textures called *Plexus Choroides* & *Rete mirabile*, but long that ſupply will not maintaine them.

Where the Animal ſpirit is prepared.

The preparation of this ſpirit is made in thoſe Labyrinths of the ſmall Arteries, their coction or elaboration (as ſome think) in the ventricles; and finally, their diſtribution into the whole body of the braine and into the ſinewes.

They therefore are in an error who do conceiue that this ſpirit attaineth his proper forme and ſpecificall difference in thoſe textures. For all the complications of veſſels as well in the braine as in the teſticles and other parts are ordained onely for preparation, but the forme and difference of a thing is ſupplied by the ſubſtance of the part, both to the Aliment and to the ſpirit.

Where labored and perfitted.

VVherefore we conclude, that in thoſe complications the ſpirits are prepared, that in the ventricles they are boyled and labored, but receiue their vttermoſt perfection in the ſubſtance of the Braine.

QVEST. VIII. *Argenterius his opinion concerning the Animall ſpirit confuted.*

Argenterius accuſeth *Galen* of inconſtancy.

ARgenterius an accute Scholler indeed, but whoſe pen eſpecially againſt *Galt* yeeldeth too much gall, in his booke *de ſomno et vigilia*, and in his Commentaries in *artem medicinalem* auoucheth, that there is but one ſpirit & that Vitall, neither will he bee brought to admit any Animall ſpirit at all. And firſt as his cuſtome is, he inueigheth bitterly againſt his Maiſter *Galen* accuſing him ſometimes of leuity and inconſtancy, ſometimes of ignorance. Of inconſtancy in his aſsignation of the matter and the place of generation of the Animall ſpirit. In the matter, becauſe ſometimes he writeth that it is made of the ayre we breathe in, ſometimes of the vitall ſpirits, ſometimes of bloud. In the place of generation, becauſe hee aſsigneth it ſometimes to bee generated in the Textures or complications of the Braine, ſometimes in the forward ventricles, ſometimes in the backward, ſometimes that it is contained in the body and ſubſtance of the braine.

He vnderſtandeth not *Galens* meaning.

But *Argenterius* wit was to nimble to faſten vpon the depth of *Galens* iudgement, which if he had well attended he ſhould not haue found repugnancy in him. For the moſt remote matter of the Animall ſpirit is bloud, the neerer matter is vitall ſpirit, the neereſt of al is ayre inſpired or breathed through the mammillary proceſſes, & conuaighed not into the textures but into the vpper ventricle. And as the matter, ſo alſo the place of their generation is manifold; for they are prepared in the Textures & vpper ventricles, boyled in the third and perfitted in the fourth or in the ſubſtance of the braine. Finally, they are diffuſed into the nerues, and from them conueighed into the bodye.

Galen accuſed of ignorance.

He accuſeth *Galen* of ignorance, becauſe from the *Net-like texture* he gathereth that ther is an Animall ſpirit, becauſe ſaieth *Argenterius*, neyther is that Texture conſpicuous in a man, neyther is there alwayes required a complication of veſſels where there is any ſpirit generated. For in the heart where the vitall ſpirit is aboundantly generated there is no ſuch admirable web of veſſels.

But defended

But *Argenterius* was ſo headily tranſported with a deſire of contradiction, that he did not obſerue the tenor of *Galens* Argument; for he neuer concludeth that therefore there is an Animall ſpirit becauſe in the braine the veſſels are intangled and interbrayded one

with

with another, but he saith that this spirit is irrigated or watered & nourished by that which that Net-like web supplyeth vnto it as we haue read in the 5. chapter of the 12, booke of his Method, and in his 7. booke *de placitis. Hip. et Plat.* and the third chapter. But let vs yeelde that *Galen* meant as *Argenterius* vnderstandeth him: shall wee therefore conclude that he hath written absurdly? Nature is not wont to create any such texture vnlesse it be for a new elaboration, but in the braine there appeareth a notable texture which we call *Choroides*, therefore in the braine there is a preparation of a new spirit. *Argenterius* wil obiect that in the left ventricle of the heart the vitall spirit is generated, and yet in the heart there is no complication of vessels. Obiection.

Wee answere, that such Laberynths were not necessary in the heart, because the necessity of the vitall spirit is greater then that of the Animall. And therefore there is a greater proportion of them required then can be confected in so narrow vessels. For the Animall functions are not perpetuall, and beside when a man sleepes they are also at rest. But the vitall, the sounder we sleepe the stronger they are. Answere.

Furthermore, all the parts of the creature haue not sence, as bones, gristles and ligaments yet all of them do liue. Wherefore because there is a greater exhaustion of vitall spirits there restauration must be ἀθρόως that is, sudden and plentifull. Adde heereto that the vitall spirit doth not onely serue for the accomplishment of the vitall functions, but also is the matter of the Animall spirits: and therefore it is necessary that their generation should be in great aboundance, which cannot be accomplished in small Arteries and narrow cauities. Finally, the heart which is the hotteſt of al the bowels doth suddenly boyle & generate spirits albeit there be not so precise a contaction in al the parts; which thing the braine being far colder cannot performe, and therfore in the brain there was great vse and necessity of complications of vessels and not in the hart. *Argenterius* proceedeth to goade *Galen* farther. Why are the Animall spirits generated in the complications of the Arteries of the brain, seeing the Arteries of the brain do not differ *in kind* from the arteries of the ther parts of the body? Now in the other parts the arteries do not generate Animal spirits; therfore they shal not do it in the brain. I answer, that the Animal spirit doth not attain his *forme & difference* in the cõplications, but eyther in the ventricles or in the substance of the brain. In those straights and narrow passages it is only prepared, and attaineth a kind of rudiment or initiation by irradiation from the braine. So in the crooked rings of the preparing vessels the seed hath a delineation from the influc e of the testicles. In the mesaraicks the blood is prepared by a vertue beaming from the Liuer: neyther did *Galen* euer acknoledge any other vse of those complications then the attenuation of the vitall spirit and the preparation of the animal. Fourthly, that there is no animal spirit he thus proueth. If in the brain a spirit wer cõtained, thẽ our sensations & cogitations should be perpetual, because the faculties of the soule are euer prest and at hand. I answere, that the soule doth not alwayes worke though it haue an Organ; because the Organ is often hindred, as when the naturall heate is drawne inward, for example in sleepe. Againe, there is not alwayes a sufficient supply of Animall spirits, and thence it is that the functions doe not alwayes worke, but sometimes rest themselues as in the night, in which time the spirits are redintegrated and refreshed; and this according to Phisitians is the onely finall cause of sleepe or rest. Fiftly, he obiecteth that thogh it should be granted that there is an Animall spirit, yet it cannot descend to the feete because it is of a fiery and airy Nature. But this argument is already answered thus: That all the spirits by their proper motion are carried vpward and outward: but when they are directed by the soule they are diffused and dispersed into all the parts of the body. So the Arme being naturally heauy, is often times depressed by his Elementary forme, yet it is lifted vp againe by the soule; for our naturall heate is by diffusion communicated to all the parts. Sixtly, if there be more kindes of spirits, then (saith *Argenterius*) it will follow that they must be mingled & confounded, which confusion of the spirits will also induce eyther a confusion or nullity of the actions. But let vs grant (which yet is not true) that the spirits are confounded, will it thence follow that euery spirit shall not performe his owne office? Why may not the vitall do the offices of life and the Animall supply sense and motion? For these spirits are not contrary, that in the permistion they should abate their power & force mutually. Seauenthly, he saith, that the pupilla or apple of the eye is dilated by the spirit of the arteries which is vitall and not Animall. On the contrary, we thinke that when one eye is closed vp the apple of the other cannot in a moment be dilated by any spirits proceeding from the arteries, because the arteries of both the eyes doe not meete and vnite themselues as do the optick nerues. *Argenterius* Argument. Answere. The fift answerd. The sixt. Answered. The seuenth.

But there is a great distance betwixt them, and so great as that it is impossible that the Vitall spirit together with the arteriall blood should so instantly mooue it self from one eye to another.

The eight. Eightly, hee obiecteth that the influence of an Animall spirite is not necessarie, a quality onely or beaming light might be sufficient, for nothing that is corporeal is moued in an instant. But we know that the Muscles obey the Braine according as our will

Answered. commandeth thē, for we are able in the twickling of an eye to moue our vtmost ioynts. We answere that the spirit which is the Organ of the soule dooth instantly accomplish the commandement thereof and is euer addrest in the Nerues, and as it is spent repayred by new influence and succession; whence it is that before the exhaustion or expense of the olde a newe is ministred to supply the roome. Which *Lucretius* in an elegant Verse hath thus chanted.

Ergo Animus cum sese ita commouet vt velit ire
Inque gredi, fert extemplo quæ in corpore toto
Per membra atque artus animali disita vis est:
Et facile est factu, quoniam coniuncta tenetur.

When the Soule listeth her selfe to disport, The Powers throughout the bodie disioyned,
Into the Ioynts and Members resort, For the Soule holdeth them alwaves conioyned.

Argenterius conclusion. Finally, he concludeth that there is but one influent spirit because there is but one soul, one influent heats, one nourishment of the parts, to wit, the blood and one aire that is inspired. These are *Argenterius* Darts which he casteth against *Galen*, which howe light they are and little sauouring of Physicke let the learned iudge. True it is that the soule is but one, but that one is furnished with diuers Faculties: there is but one Aliment, but by diuers concoction it receyueth a diuers forme, and that one according vnto the diuers substance of the parts is of diuers sorts.

Our conclu- on. As therefore there are three Faculties of the Soule, the Naturall, Vitall and Animall; three principles, the Braine, the Heart, and the Liuer; three Organs ministering vnto them Veines, Arteries and Nerues: so are we to thinke that there are three spirites distinct in forme and kinde, otherwise all thinges should bee one because the common matter of all is one and the same.

Other reasons to prooue there is no Animal spirit. There be other weapons farre keener then these of *Argenterius*, wherwith we may affront the opinion of *Galen* concerning the Animall spirit, which for disputation sake and that the truth may be better cleared we will thus vrge. Whatsoeuer spirit is conteyned in the Cauity of the Arteries is to be accounted Vital. But all the spirits conteined in the Braine are included within the Arteries, neyther doe they euer yssue out of them, and therefore the spirits of the Braine are Vitall and not Animall.

The first. The Minor proposition or assumption is thus confirmed. If the spirites boult out of the Arteries then are they conueyed either into the Ventricles or into the substaunce of

The answere. the Brain, which if we admit, then wil the spirit becom presently condensed. For the scalding Vapors which arise into the Braine from the bowels boyling with extraordinarie heate are much thinner then the spirits and yet are instantly condensed or thickned.

Now that the Vapor is thinner then the spirit may be prooued, because the vapour exhaleth outward, the spirits remaining within. To this argument wee answere, that the Nature of Spirits and Vapors is diuers. The spirits are retained by the Soule, beecause they are familiar and as it were of Kin vnto her, but the Vapors are straungers or rather Enemies, and therefore they exhale and are condensed or thickned.

Another Reason.

The second. If the Spirits of the braine do forsake the Arteries and be transfused into the Ventricles, seeing in the third Ventricle there are two passages, one forward and another backward, why do they rather passe backward then forward? whereby shal it bee conducted

Answered. after it fal out of the Arteries so that it mooue in a right line, and that without any violence but with an easie and gentle motion into the fourth Ventricle. I answere, that it is the Soule that directeth the Instruments of the soul, and that it is diffused into this part rather then into the other, because it is the Soules good pleasure so to command.

The third. Thirdly, it seemeth not consonant to reason that a Spirit should be generated & conteyned in the Ventricles of the Braine, because those Ventricles were ordained for the

Answered. expurgation of superfluities. I answere, that Nature vseth one part for diuers vses, for as the Nose was primarily created for smelling and the inspiration of aer, and secondarily for the expurgation of the Braine; so it may be that the forward ventricles of the braine

were

were primarily made for the preparation of the ſpirits, and ſecondarily to auoide excrements.

Fourthly, that whereas one eye being ſhut, the apple of the other is dilated. It argueth that the ſpirits are not tranſported by the nerues but by the Arteries. For the optick nerues do not touch the apple of the eye, yea betwixt them are interpoſed many boddies and thoſe very thicke, to wit, the Chriſtaline and the Wateriſh humors, through which the ſpirits in ſuch a momẽt cannot paſſe. For if it cãnot pearce through a drop of phlegme in the oppilation or ſtopping of the optick, which maketh the diſeaſe we call *Gutta ſarena*; how ſhall it paſſe the thickneſſe of the Chriſtaline humor? The ſpirit therefore yſſueth through the ſmall Arteries, which together with the *grape-like* coate are conuyghed to the *Pupilla*. This reaſon would vrge very much vnleſſe Anatomy did teach vs that the opticke nerue when it commeth vnto the Chriſtaline humor doeth not there determine but is diffuſed and amplified into that coate which is called *Reticularis* or the Net. Now the *Net-like* coate paſſeth euen vnto the apple. The fourth. Anſwered.

Finally, that there is no Animall ſpirit may thus be demonſtrated. The ſpirits are thoſe that do conueigh and tranſport all the faculties, and ſerue onely for that vſe. Now there is no Animall faculty tranſported from the braine into the body, and therefore there is no Animall ſpirit. That the Animall faculty is not tranſported from the braine into the body may thus be prooued. The fift.

A faculty is a propriety of the ſoule, now euery propriety is inſeparable from that thing whereof it is a propriety. Wherefore whereſoeuer the ſoule is, there alſo ſhall his faculties be. But we know that the ſoule is *Tota in toto et tota in qualibet parte*, that is, wholy in in the whole and wholy in euery part. Whence it will follow that the faculty is not only in the braine but alſo in euery part of the body, and that as abſolute and perfect as it is in the braine it ſelfe, becauſe the whole ſoule is abſolute and perfect in the leaſt part.

The Philoſopher makes anſwere, that the eſſence of the ſoule furniſhed with all her faculties is indeed euery where; but doth not worke euery where becauſe euery where it hath not Organs. For the Soule doth not moue neyther partaketh of ſenſe without the Animall ſpirit, as it ſeeth not without an eye. Anſwered.

We conclude therefore that there is an Animall ſpirit which receiueth an inchoation in the Textures, an elaboration in the ventricles, & a perfection in the ſubſtance of the braine, where alſo it is the vehicle of the principall faculties, and paſsing into the ſpinall marrow and the nerues is the immediate Organ of ſenſe and motion.

QVEST. IX *Whether the braine be moued by a proper & In-bred faculty, or by the motion of the Arteries.*

IT is a very hard and difficult queſtion whether the brain be moued by a proper and ingenit power of his owne, or by ſome outward violence. That the braine is moued no man in his right wits will deny vnleſſe he bee vtterly ignorant of Anatomy. For in great wounds of the head wherein the Scull is broken and the membranes are detected, there is a manifeſt motion to be ſeene. Againe, in children newborne the forepart which we call the mould of the head doth ſo conſpicuouſly pant and beat, that the very bones of the Scull which at that time be exceeding ſoft are moued therewith. That the braine is moued voluntarily.

But becauſe among the Philoſophers there is a threefold kinde of motion, the firſt naturall, the ſecond Animall, and the third violent. It is a great queſtion to which of theſe kindes the motion of the braine is to be referred. It ſeemeth to ſome that the braine cannot be the originall of the Animall motion vnleſſe it ſelfe be moued voluntarily; for it were abſurd to ſay that there yſſued from the braine into the whole body a power or faculty which doth not reſide therein as in the fountaine and originall.

But this opinion hauing no ſtrength of argument to ſupport it, hath alſo beene little ventilated by the Phiſitions. For an Animall motion is *proairetical*, or with choice being intended, remitted or intermitted according to the arbitriment of our will. Now wee know that the braine is not moued at our diſpoſe, but according to it owne inſtinct, and therefore the motion thereof is not voluntary.

No man will ſay that it is violent; for *Ariſtotle* in his ſecond book *De ortu*, oppoſeth that which is violent to that which is according to nature. It remaineth therefore that it is naturall By naturall I vnderſtand not that which is only directed by Nature, but whatſoe- Diſproued. That it is not violent.

uer is not voluntary although it be gouerned by the ſoule.

Now whether this motion be of the whole braine or onely of the parts, and whether it be moued by an in-bred faculty or a power from without, that is, from the Arteries and the ſpirits it is greatly contrauerted. *Galen* in the ſecond chapter of his fourth booke *de differentijs pulſuum* ſaith, that ſome thinke that the membranes onely do beate, others only the body of the braine, others both the membranes and the braine it ſelfe. Some are of opinion that the Animall ſpirits onely are moued not the bodye of the braine, which they illuſtrate by the example of a *Vertigo* or giddineſſe wherein all things ſeeme to runne round, becauſe of an inordinate and Turbulent motion of the ſpirits. The vulgar opinion is that the braine is not moued by any proper motion of it owne, but by a motion from without, that is to ſay, from the Arteries. Neither do his ventricles breathe in aer, (as *Galen* would haue it) neyther are they diſtended and contracted.

The first opinion.

That the braine is moued according to the motion of the arteries Reaſon 1.

The reaſons of this are: firſt it doth no more become a principle of motion to bee mooued, then it becommeth a principle of ſenſe it ſelfe to haue ſenſe, becauſe as *Ariſtotle* ſaith, euery αἰσθητήριον muſt be ἄτρωτον that is, euery inſtrumēt of ſenſe muſt be deſtitute or void of al the obiects of that ſenſe whereof it is an inſtrument: now the body of the braine hath not ſenſe and therefore it hath no motion.

Furthermore, if the braine doe breath by a proper power, it would follow that becauſe the ſubſtance thereof is ſoft, and the membrane that compaſſeth the ventricles very fine & thinne, it followeth I ſay, that that membrane muſt in the dilatation & contraction be violently torne aſunder.

Thirdly, the third and fourth ventricles of the brain commonly ſo called, are of the ſame ſubſtance and temper that the vpper ventricles are of; for the vſe of them all is one and the ſame; but it is granted that the latter ventricles doe not Reſpire, and therefore neyther ſhall the former be dilated or contracted.

They vrge further and thinke that this weapon hath a further edge. In grieuous wounds of the head when the braine is vncouered, the motion of the braine and the arteries doeth not appeare to differ at all, but as one Pulſe is anſwerable to another, ſo likewiſe the motion of the braine and the arteries doe accord. Now if the braine did beat by an in-bred power, then muſt it needes be that ſome time the braine and the arteries ſhould not beat alike and at the ſame inſtant.

Finally, there is no Attraction, no Expulſion without the helpe of fibres: ſo the heart hath his fibres, as alſo the ſtomacke, the guttes, the veines and the arteries; but in the brain there appeare no fibres at all; *Ergo* the Motion of the *Diaſtole* and *Syſtole* of the braine is not proper and peculiar vnto his ſubſtance.

Verily theſe reaſons are ſo ſtrong that the time hath bin (ſaith *Laurē.* whē I was cōuinced by them & conſtrayned to ſubſcribe vnto this opinion; but looking ouer with a little more diligence the works of *Galen* and conſidering ſome paſſages in his Booke *de Odoratus Organo, de vſu partium, de Placitis Hippoc. & Platonis* with better deliberation, at length I altered my minde, and am now reſolued that the body of the braine doeth reſpire by a proper faculty and in-bred Motion.

That the braine doth reſpire by it owne force.

Let vs here *Galen* diſputing in expreſſe words in the laſt Chapter of his Book *de Odoratus Organo, Nature ſayeth he hath not denyed motion to the braine whereby it might draw Ayre for his refrigeration and returne the ſame backe againe for the expurgation of ſuperfluityes.* Againe in the 4. Chapter of the ſame Booke, *It is not impoſſible that the brayne ſhould yeeld vnto it ſelfe a kinde of Motion (though it be but ſmall) ſometimes into it ſelfe ſometimes out of it ſelfe, ſo that it ſhould be leſſe when it contracteth it ſelfe, and more ſpred when the parts of it are dilated.* Thus farre *Galen.*

The authority of *Galen.*

Reaſon. 1.

But it ſhall behooue vs to eſtabliſh his authority by reaſon alſo and waight of argument. It is moſt certaine that the Animall ſpirit is generated firſt in the vpper ventricles of the braine, which ſpirit being of it owne Nature ayrie and hot, ſtoode neede of the Inſpiration of ayre which was familiar and of kin vnto it, as well for his nouriſhment as that by it it might be refrigerated: wherefore when we draw our breath inward, the ayre alſo is drawne into the braine, and when we breath outward a fumid or ſmoaky vapour which is the excrement of the Animall ſpirit is thruſt out and auoyded.

Hippocrates.

This *Hippocrates* elegantly expreſſed in his Booke *de morbo ſacro* or of the Falling ſickneſſe. *When* (ſayth he) *a man drawes in ayre by his mouth & his noſe is ſhut, firſt of all the breath commeth to the Brayne.* Nowe this Inſpiration of the ayre into the vpper ventricles of the braine

braine and the Expiration of the ſame is not made by arteries, but by certaine protuberations or ſwelling productions of the braine much like the Nipples of a womans Pap, which alſo are the Organs of ſmelling. The Motion therefore of the braine which is accompliſhed by Inſpiration and Expiration proceedeth from the braine it ſelfe not from the arteries. Againe, that the ayre is drawne in by theſe productions may thus be proued.

The ayre and odours doe paſſe by one and the ſame way, for no ſmell can be felt although it be driuen violently into the noſe vnleſſe therewith ayre be drawne in: now odors do paſſe into the braine by thoſe productions before named, not by Arteries: and therefore by the ſame productions ayre is inſpirated and tranſported into the foreward ventricles.

Furthermore, if the braine do beate by the Arteries and not by anim-bred power for the generation of ſpirits; why then is not the ſpinall marrow alſo moued? You will ſay haply, that in the marrow of the backe there is not ſo great plenty of Arteries as are found in the braine it ſelfe. I anſwere, it may well be, for there is not the ſame quantity of matter or ſubſtance in the braine and the marrow. But if you compare both bodies together, then will the proportion of the Arteries be as great which runne through the membranes inueſting the marrow. Wherefore the ſpinall marrow is not therefore immoueable becauſe it wanteth arteries, but becauſe in it there is no generation of vitall ſpirits as there is in the Braine. Reaſon 2.

The third argument is on this manner. There is a certaine diſtance betwixt the body of the braine and the *Dura meninx*; not to giue way to the *Syſtole* and *Dyaſtole* of the Arteries for they are not ſo lifted vp; nor to auoid danger becauſe the *Pia mater* or thin membrane is interpoſed betweene them: the diſtance therefore is left for the motion of the braine, and ſo we ſee that in the heart there is a diſtance betwixt it and the *pericardium*, leaſt if they had touched one another they might haue beene interrupted. Reaſon 3.

Fourthly, how is it poſsible that ſo great a waight and maſſe of moyſture as the braine is, ſhould be dilated by a few ſmall arteries? (for ſo I worthily call them that are ſprinckled through the body of the Braine) ſeeing that the large and notable Arteries of the ſpleene are not able to moue his rare and final body? I anſwere, Anatomy teacheth vs that this bowel is wouen with infinite Arteries, and yet no man euer ſaide that the ſpleene was moued vnleſſe it be in a tumor or inflamation, and then any part will be moued. Reaſon 4.

Fiftly, if the motion of the braine bee the motion of the Arteries and not of the marrowy ſubſtance, then it was ridiculous to ſay that the braine is moued becauſe the Arteries are onely moued. For ſo we might ſay that the ſtomack, the guts and the ſpleene were mooued becauſe the Arteries do beate euery where. And therefore if wee imagine that the marrow of the braine is diſtended by the *Dyaſtole* of the Arteries, why ſhould we not beleeue alſo that all the reſt of the parts of the body do beate, becauſe they haue all proportionably as many Arteries? Reaſon 5.

Finally, the proceſſe called *vermi-formis*, the *Conarion* and the buttocks of the braine do ſhew that there is a peculiar motion of the braine which differeth from the motion of the Arteries. For the wormy proceſſe being made ſhorter, openeth the way which is from the third vnto the fourth ventricle, and whilſt the ſame proceſſe is extended it ſhutteth the paſſage againe leaſt the ſpirit ſhould returne into the vpper ventricles: ſo that it ſeemeth there is the ſame vſe thereof that there is of the values placed at the mouth of the great Artery: now the opening and ſhutting of this clift proceedeth not from the Arteries, but from an in-bred power of the braine it ſelfe. It is therefore more probable to thinke with *Galen* that the braine is moued by a naturall motion and that proper to it ſelfe for the nutrition of Animall ſpirits, the tempering of them and their expurgation. Reaſon 6. The Concluſion.

The reaſon and nature of this motion is on this manner. When the braine enlargeth it ſelfe it draweth ayre out of the noſtrils by the mammillary proceſſes and ſpirits out of the Textures or complications of the ſmall Arteries. This ayre and theſe ſpirits it mingleth in that reſt or *interim* which is between the two motions: but when in the *Syſtole* it contracteth it ſelfe the ſides falling together, the inward ventricles are ſtraightned and the Animall ſpirits powred out of the foremoſt into the hinder ventricles. The reaſon of the motion of the braine.

But heere ariſeth a ſcruple of no little moment, which is, whether the ayre is deriued to the braine when it is diſtended or when it is contracted? It ſhould ſeeme that the ayre is drawn in in the conſtriction, becauſe when the brain is contracted it departeth a little from the Scull: the Scul becauſe it is immoueable doth not follow the contraction of the brain. A great queſtion.

It is therefore neceſſary that there muſt bee a vacuitie betweene the Braine and the Scull, or elſe there muſt be aire drawne in, wherewith that place muſt be filled.

What wee thinke. But wee thinke that the aire is drawne in in the dilatation of the braine, neither doe we allow that there is any emptie place left in the contraction, becauſe in the contraction there is an expreſſion of aire and fumed vapours through the ſutures. Now let vs giue anſwer to that which is obiected againſt this our opinion.

They obiected firſt. That the braine is the beginning of motion, and therefore ought not to be moued. We anſwer, That indeed it muſt not be moued with the ſame Motion wherewith it moueth the parts: It giueth to the parts of the body voluntary Motion, but it ſelfe is moued with a naturall Motion. The braine is moued after the ſame manner that it hath ſenſe: Now the ſenſe of it is naturall as is the ſenſe of bones or the bowels, whereby it being prouoked, auoydeth that which is offenſiue vnto it, as we may ſee in ſneezing and in the falling ſickeneſſe. It is moued for the generation of animall ſpirits.

The reaſon of the contrary opinions are anſwered

To the firſt.

To the ſecond. Their ſecond argument was, that the ventricles of the braine did not reſpire, becauſe in that perpetuall diſtenſion the thin Membrane of the Braine would haue beene broken: But they do not remember that in ſneezing and in the Epilepſie, the contraction of the Braine is more violent then in the ordinary Motion; & yet in neither of thoſe is the Membrane broken. In Sternutation or ſneezing, the Braine collecteth it ſelfe and is contracted the better to exclude that which is offenſiue vnto it. For the ſame that the cough is in the cheſt, and the hickocke in the ſtomach, the ſame is ſneezing in the Braine. In the Epilepſie the whole Braine is contracted and corrugated.

To the third. Thirdly, they obtrude vnto vs: that the backeward ventricles do not reſpire, and therfore that the forward ventricles doe not dilate or contract themſelues. I anſwer, firſt that I know not by what ſlight or art they can perceiue that the backeward ventricles doe not moue. But let vs grant that they doe not, yet is their conſequence not good; for the formoſt ventricles doe ſtand in neede of more, at leaſt of more conſpicuous Motion then the other, becauſe in the formoſt the ſpirit is prepared and purged, in the backeward they are contained when they are pure, ſincere and alreadie purged.

To the fourth Fourthly, the motion of the braine and the arteries doth not appeare to bee vnlike the one vnto the other. I anſwer, that they are not indeede vnlike, becauſe their vſe is the ſame, there is the ſame finall cauſe of the generation of the ſpirits & of their expurgation.

To the fifth. Fiftly, they doe not thinke it as moued with any proper motion, becauſe there appeare in the braine no *fibres* at all. Wee anſwer, that the bones doe draw their nouriſhment, and expell that which is ſuperfluous without the helpe of Fibres.

To the laſt. Laſtly, there is not the ſame reaſon or nature of the heart and of the Braine: for the Heart ſtood neede of Fibres not for the traction and expulſion of aire but of blood. In the *Dyaſtole* the Heart draweth blood by the right Fibres, and the ſame blood it expelleth in the *Syſtole* by the tranſuerſe. But the Braine when it is mooued draweth onely aire with moſt thinne vitall ſpirits, for the traction whereof there is no neede of the helpe of Fibres. Hence we thinke it is ſufficiently manifeſt, that the Braine is moued by an in-bred facultie, and not onely by the motion of the arteries.

QVEST. X. *Whether the Braine hath any ſenſe.*

That the brain hath ſenſe. The authority of *Hyppocrates*. Of *Galen*. Experience. Reaſon.

IT is a notable Controuerſie amongſt Phyſitians, whether the Brain haue any ſenſe or no. That it hath ſenſe it may bee demonſtrated by authoritie, experience and reaſon. *Hippocrates* in his Booke *De vulneribus capitis*, reſolueth that it hath ſenſe where he ſaith, *That the braine about the ſinciput doth ſooneſt and eſpecially feele any inconuenience that is either in the fleſh or in the bone.* *Galen* in his booke *De plenitudine*. The Braine (ſaith he) and the ſpinall marrow are accounted amongſt thoſe things which haue ſenſe. And if in a frenſie no paine be felt, it is becauſe the mind is diſquieted. Againe in his book *Odoratus organo* he attributeth to the Brain manifeſt ſenſe. Moreouer experience and ſenſe do confirme the ſame. *Galen* in the 4. chapter of the aforeſaid book, telleth a ſtorie of a certaine man whom hee commanded to ſnuffe vp into his noſe, and to receiue at his mouth *Nigella*, Gith or Pepperwort finely beaten and mingled with old oyle, who thereupon felt a great gnawing in his braine. Which (ſaith he) is a manifeſt argument that ſome of that *Nigella* went into the ventricles of the Brain, and cleauing to the *Pia mater* or thin Membrane, or elſe haply in the Braine it ſelfe, was the cauſe of that paine.

Againe

Againe, reason seemeth to perswade the same. The Braine is the fountaine and originall of all sense, and therefore it selfe must need be sensible, because by it all other parts haue sense. For it is an axiome in Logicke, *Propter quod vnumquodque est tale, & illud magis tale. That for which any thing is such or such, must needs it selfe be more such or such.* Furthermore, vnlesse the Braine had sense, it could not rouse it selfe vp to the expulsion of that which is offensiue: for in sternutations or sneezings, and fits of the Epilepsie or falling-sicknes, how should the Braine bee moued and shaken to exclude and auoyde the humour or vapour by which it is vellicated or goaded vnlesse it felt the affluence thereof?

Contrarily, the opinion of those who determine that the Braine hath no sense, may also be confirmed by authoritie, experience and reason. *Aristotle* in the 17. chapter of his 3 booke *De historia Animalium*; And in the 7. capter of his second booke *de partibus Animal*: writeth, that the Braine and the marrow haue not *sensum tactus* the sense of feeling. *Galen* in the 8. chapter of his first book *De causis sympto.* The Braine (saith he) was ordained by nature, not to haue sense but to communicate the faculty of sensation to the instruments of the senses. In his third booke *De causis sympt* hee calleth the Braine an Organe without sense. The contrary opinion.

Experience, then which nothing is more certain, conuinceth the truth of this position. For when the Braine is wounded the patient doth not feele although the substance therof be pressed with a sharpe probe, no not if some of it be taken away, which thing is very ordinary for Physitians and Chyrurgions to obserue. Experience.

Finally, it may be demonstrated by reasons. Euery Organ (saith the Philosopher) must be ἄποιον that is, *without any externall quality.* So in the Christaline humor of the eye there is no colour, in the eare no sound, in the tongue no sauour; and the skin which is the iudge of those qualities which moue the sense of touching is it selfe of a moderate temper. So the braine is the seate of the common sense and iudgeth of all sensation, and therefore must it selfe be without sense. Reasons.

Moreouer, the braine ought not to be sensible, for if it were hauing his scituation vppermost and like a cupping glasse drawing and supping vppe the exhalations of the lower parts it would by their affluence perpetually be payned.

Finally, the substance well nigh of all the bowels is insensible, as of the liuer the spleene, the lungs, &c. and therefore the substance also of the braine is insensible.

To this opinion we rather subscribe then to the former, following therein *Galen* in his first booke *de causis Symp.* where he is not of opinion that the braine hath sense, but onely that it can discerne the differences of sensible things.

Those things which are brought to proue the contrary assertion, seeme to me now to be very light. *Hippocrates* sayde that *the braine did feele those iniuries that were in the flesh and in the bone*, that is to say, it is affected and altered by them. So the same *Hippocrates* saith in his Aphorismes that the bones do feele the power of cold, that is, they are altered by cold. Wherefore he vseth the word Sense in that place abusiuely. *Galen* attributeth sense to the braine. It is true, yet not to his marrowy substance which is the fountaine and originall of all the Animall faculties, but to the *Pia mater* or thin membrane which insinuateth it selfe deepely into the corners thereof. As for that logicall Axiome, it is only true in these causes which we call Homogeny, and those also conioyned. For the Sunne being of it selfe not hot yet heateth all sublunary things. And whereas they say that the braine is shaken in the exclusion of that which is hurtfull, and thence would proue that it is sensible; wee answere, that there is seated in euery particular part a naturall power to expell that which is hurtfull; which power is sometime ioyned with Animall sense, sometimes also it is without the same. So the bones haue a power of excretion, and the flesh almost of all the bowels being insensible, is yet apprehensiue of those things that are hurtful, yea expell them also and driue them forth. There are in the nature of things certaine *Sympathies* and *Antipathies*. Answere to the arguments of the former opinion. How the braine apprehend that which is hurtfull.

Fernelius in the tenth Chapter of the 5. booke of his *Physiologia* hath diuised a new and vncouth opinion concerning the motion and sense of the braine. He conceiueth that all motion is from the marrow of the braine, and all sense (saith hee) floweth from the Meninges or Membranes: because the body of the braine is perpetually mooued, & yet hath no sense at all; on the other side the membranes that incompasse it are of themselues immoueable, especially the *Dura mater*, and yet their sense is most exquisite. So in the diseases which we call *Dilirium*, that is, an aberration of the minde and in the Letargy which *Fernelius.* new opinion.

are

are affects of the Braine there is no paine at all: but if a ſharpe humor or vapour be tranſported into the Membranes, then is the patient as it were on the racke.

Furthermore, the ſpine and all the nerues haue their marrow from the braine and the ſame inueſted with membranes: al which haue the ſame power and nature which they receiued from their originall. Therefore the fore-part of the braine is the originiall of ſenſe, the backepart the beginning of motion and the menings or membranes are the beginning of *touching*. Thoſe nerues that are fulleſt of marrow are the inſtruments of motion, but thoſe are the inſtruments of touching which are for the moſt part deriued from the meninges.

Fernelius his firſt error.

Theſe are *Fernelius* words, wherein, ſaith my Author, by the fauor of ſo great a man, I finde ſome things that cannot be warranted. Firſt he ſaith that all voluntarie motion floweth from the Marrow becauſe the Marrow is perpetually mooued, as if the motion of the Braine and of the Nerues and Muſcles were alike. The motion of the Braine is Naturall conſiſting of a *Dyaſtole*, a double reſt and a *Syſtole* for the generation of Animall ſpirits, but the motion of the Muſcles and the Nerues is voluntary.

Second.

Furthermore, we are not to thinke that the Nerues are ſo much the fitter for motion by how much they haue more marrow; rather we beleeue the contrary, that the harder Nerues are fitter for motion and the ſofter for ſenſe, becauſe ſenſation is a paſſion but motion an action; we know alſo by experience that the Opticke Nerue which is the ſofteſt of all the Nerues hath more Marrowy ſubſtance then the Nerue of the ſeconde Coniugation, yet the Opticke is the Nerue of Senſe, the other the nerue of Motion.

Add heereto, that Motion ſhould bee rather aſcribed to the Membranes then to the Marrow, becauſe the Marrow melteth away but the Membrane is ſtretched & contracted: ſo the Nerues of children are weake and ſoft and vnfit for motion. To all theſe let vs add the authority of *Galen* in the third chapter of his ſeuenth Book *de Placitis Hip. & Platonis*, where he ſaith, that the faculties of Motion and Senſe are only conteined in the Marrow of the Braine and that the Membranes were made to cloath and noriſh the Marrow & for no other vſe.

The authority of *Galen*.

We conceiue therefore that this Paradox although it be witty, yet will not holde at the Touchſtone, and therefore we determine that the Marrow of the Braine is without all ſenſe and Animall motion, and yet is the fountaine and originall of all Animall Senſe and motion. Of Senſe, becauſe it perceyueth the repreſentations and receyueth the impreſsions of all ſenſible things. Of Motion, becauſe it diſpenſeth and affoordeth al that power and command for the auoyding of that which is noxious, and proſecution of that which is profitable; from whence it commeth to paſſe that when the Braine is il affected the inferior parts haue neither Senſe nor Motion.

The Braine hath neyth r ſenſe nor motion, and yet is the original of both.

QVEST. XI. *Of the Temperament of the Braine.*

THE Phyſitians and the *Peripatetikes* in this do agree, that the brain in the Actiue qualities is cold, in the Paſsiue moyſt. But heere in they differ, that *Ariſtotle* in the ſeuenth Chapter of his ſecond booke *De partib. Animalium* and in the fift Chapter of his booke *De Somno & Vigilia*, determines that the braine is actually cold and ordained to refrigerate or coole the heart. Contrariwiſe, the Phyſitians ſay that it is Actually hot. For *Galen* in his eight booke *De Placitis Hip. & Platonis* ſaith, that the brain is hotter then the moſt ſoultry aer in ſummer. Some there are that do thus reconcile *Galen* and *Ariſtotle*; There is (ſay they) a double temperament of the braine, the one In-bred, the other Influent: by the In-bred temper, the proper compoſition and the marrowy ſubſtance, the braine is very cold; but by the influent temper it is hot, for it is full of ſpirits and intertexed with very many ſmall Arteries.

Reconciliatiõ of *Ariſtotle* and *Galen*.

If you reſpect the in-bred temper, then is the temperament of the braine and the ſpinall marrow one and the ſame, becauſe they haue the ſame marrowy ſubſtance. If you reſpect the Influent temper, then ſaith *Galen* in the ninthe chapter of his ſecond booke *De Temperam.* the braine is hotter then the ſpinall marrow, as well becauſe there paſſe vnto it more Arteries, as alſo becauſe many fumid exhalations do aſcend vnto it. Some ſay, that the braine is ſimply and abſolutely hot; but colde comparatiuely, becauſe it is the coldeſt of all the bowels. And *Galen in Arte medica* writeth, That a hot braine is colder then the coldeſt heart. In which reſpect *Hippocrates* in his booke *de Glandulis* calleth the

the braine μητρόπολιν τοῦ ψυχροῦ *the Seate of Coldnesse.* But I cannot approue this opinion. For if the brain be colder then the skinne which is in a meane betwixt the extremes, then it is simply cold and not hot. Now that it is colder then the skin *Galen* teacheth in his second booke *de Temperamentis.*

It will be obiected, that if the braine be laide bare it will presently be refrigerated by the aer, whereas the skin is not affected therewith. I answer, that the braine is altered by the aer, because it is not accustomed thereto as the skinne is; so the Teeth beecause they are accustomed to the aire do not grow blacke as other bones do if they bee layde bare. Or againe, that the braine is hotter to feele to then the skin, because it is couered with the scull and the membrane and hath many complications of the arteries therin. We determine therefore that the Braine of his in-bred temper is colder then the skin, but by his influent temper is hotter. That the Braine should be colde it was very necessary least a Member set a part for continuall cogitation or discourse should bee enflamed and set on fire. Againe, that the animall spirits which are very fine and subtill might be retained and not vanish away. Obiection. Solution. Why the braine ought to be cold.

Finally, that our Motions and Sensations should not be rash or phanaticall as they are in such as are phreneticall, that is, haue their braines inflamed. It may be obiected, if the Braine be cold, how then doth it ingender animal and attenuate vitall spirits; for these are the workes of a vehement heate? I answer, that the spirits are attenuated in the textures of the small arteries, & in the strayghtes of those passages: & that the animall spirit is formed not so much by any manifest qualitie such as is heate, as by an in-bred and hidden proprietie. Obiection. Solution.

But the reason why the spirits of the extreame hote Heart are thicker then those of the very cold Braine must not be referred to the weaknes of the heate which is the worker, but to the disposition of the matter which is the sufferer. For the heart maketh vitall spirits of of thicke blood brought vnto it through the hollow veine: the Braine maketh Animall spirits of subtill and thin vital blood and spirits: so a weaker heate boyleth a thin and easily concocted aliment, whereas a very strong heate will hardly ouercome a thicke aliment. It remaineth therefore that in the actiue qualities the braine is cold. Why the spirits of the extreame hot heart are thicker then the Animall spirits.

That in the passiue qualities it is moist both by the in-bred and influent temper no man I thinke is vnresolued: for it appeareth euen to the touch. Now it was by nature created moist, as well for more perfect sensation, (for sensation is a passion; and those things that are moyst do more easily receiue the images and representations of things offered vnto them) as also for the originall and propagation of the nerues which would not haue beene so flexible if the braine had beene hard. Adde heereto that if the braine had beene hard it had also beene heauy and the waight and hardnesse thereof would haue bin offensiue to the sinewes. Why the braine was made moist.

Finally, it was made moist least being a member destined to perpetuall motion sensation and cogitation it should haue beene inflamed if the moysture had not bin an impediment thereto. But if you compare the two qualities together, then we say that the braine is more moist then cold: for amongst the moist parts it hath a third place, among the cold parts almost the last.

QVEST. XII. *How many and what are the Excrements of the Braine, and by what wayes they are purged.*

THE Braine being of a medullous or marrowy substance and by his naturall temper colde and moist because it is nourished with flegmaticke blood, heapeth together a great aboundance of excrements. Why the brain aboundeth with excrements.

Moreouer, being as it were the Chimney of the whole body, or the head of a Still (whose figure also it representeth) it sucketh and draweth from the lower parts all kindes of expirations as *Hippocrates* teacheth in his booke *de Glandulis* wherevpon it beecommeth filled with vapors and as it were drunke with their continuall affluence and so stableth in it selfe a masse of superfluity; so that it aboundeth with excrements as well of it selfe, that is, it of own nature because it is cold & moist, as also by euent for that it is seated in the vppermost place whether all vapors do resort.

These

Thicke.

Thinne.

These excrements of the braine, if wee beleeue *Hippocrates* and *Galen* are of two sorts, some are thinne and some are thicke; the thinne like vapour or soote do expire or exhale vpward by insensible passages; the thicke are purged downeward by open and conspicuous wayes. VVith the thinne and vaporous exhalations the braine is cloyed onely by reason of his scituation, for all fumes doe arise vpward; and beside all vessels doe determine in the head. But it aboundeth with these crasse and thicke excrements aboue other bowelles by reason of the cold and moyst temper thereof.

The kinds of thick excrements.

Of these thicke excrements some are phlegmaticke, waterish and serous; some are bilious, some melancholy. The waterish is generated of the reliques of the phlegmatick and crude bloud: the bilious or melancholly out of the earthy portion of the Aliment torrified by the violence of heate, and therefore they grow bitter.

Argenterius his error concerning the flegmatick excrements of the braine.

Argenterius is of opinion that that watrish and mucous humour which is auoyded partly by the nose partly by the mouth and pallat, is not the proper excrement of the brayne, because many men and women doe seldome or neuer spit, and as seldome auoyd any moisture by the nose; but sayth it is a humour ingendred in the liuer mixed with the bloud and contained in the veines, which is not generated in the braine vppon the concoction of the Aliment, but is thither deriued from below: and because through the weaknes of the concoction and cold distemper it cannot be assimilated by the braine, it returneth back again as a redundance or superfluitie and is cast out by the mouth & by the nose. VVhich assertion of his if it were true, what reason had nature to place in the saddle or seat of the wedge-bone that kernelly and spongie flesh? was it not appoynted to receiue this very excrement? If this phlegmaticke humor were onely generated in an intemperate braine, what vse were there of the glandule which is found in all braines though most temperate? Nature is too wise and prouident so rashly to frame any part where there shal not be continuall vse thereof. In this opinon therefore of *Argenterius* wee can finde no vse either for the *Tunnell or the phlegmaticke Glandule* if the braine be not distempered. Moreouer, it is not true that he sayeth, that those whose braines are temperate doe not spit phlegme or auoyde mucous matter by their nose: for *Galen* in the 13. Chap. *Artis parua* teacheth, that in a brain which is most temperate the excrements that are purged by the nose and by the pallate (such as are watrish and mucous excrements) are in moderate quantity: neither are we to attribute it vnto perfect sanity when we finde those excrements by the passages not to bee auoyded. VVherefore we conclude against *Argenterius* that these phlegmatick and mucous humors are the proper excrements of the braine, because in the braine they haue peculiar conueyances and channels by which they are auoyded, framed by Nature onely for their euacuation.

Confuted.

Hauing thus determined concerning the differences of the excrements of the braine, let vs now see by what passages euery of these excrements are auoyded.

By what waies the thin excrements breath out.

The thin and fuliginous excrements arising vpward because of their leuitie, doe expire or breath out through the Meninges, the Skull and the Skin. Through the Meninges and the Skinne not by any sensible or conspicuous way but by insensible exhalation; for their bodies while a man is aliue are infinitely perforated or at least peruious with many small holes. But these sooty vapours because they could not passe the thicknes and density of the bones, therefore is the Skull distinguished with sutures or seames, so that it consisteth not of one bone but of diuers ioyned together by those sutures, through which as also through the holes which are thrilled betwixt the tables of the Skull these thin excrements and fuliginous vapors do exhale.

The waies of the thick excrements.

Hippocrates.

But the thicker excrements descending downeward by their Naturall and Elementary forme, haue manifest and conspicuons passages, concerning which Physitions doe not so perfectly agree among themselues; *Hippocrates* in his Booke *de locis in homine & de glandulis*, acknowledgeth seauen wayes by which the humour passeth out of the braine, that is, through the nose, the eares, the eies, the pallat, into the throat & gullet through the veins, into the spinall marrow and into the bloud.

Galen.

Galen in his 13. Chapter *Artis parua*, saith there are foure passages, the pallat, the nose, the eares and the eies. The same also he saith in the third Chapter of his second Book *de locis affectis*, and in his first Booke *de sanitate tuenda*: but in his Commentary vpon the 21. Aphorisme of the first Section, hee nameth onely the pallate and the nose, as also in the first Chapter of his 9. Booke *de vsu partium*, where hee sayth, the passages of the braine which bend downward doe send out the thicke excrements as well by the pallate into the mouth

mouth, as also by the body of the Nosethrils, and these passages are large and conspicuous. In his first booke *de symp. Causis* and the 8 *de vsu partium* he saith, that the pallate alone is the fit way of expurgation when the creature hath good concoction, and that the nosethrils do onely serue for the inspiration of aer and odours.

In his Commentary vpon the 24. Aphorisme of the third Section he writeth, That the expurgation which is made by the eares is not naturall vnlesse it be in litle children by whose eares we often obserue that their braines are purged.

Places in *Galē* reconciled.

In his Commentary vpon the 20. Prognost. of the first Section he saith, that the expurgation by the eyes is not naturall. Thus *Galen* seemeth to be of a diuers opinion concerning these passages of the braines excrements. But that we may reconcile these different places and freely professe what truly we are to resolue of; wee thinke that the diuers excrements of the braine, Phlegmaticke, bilious and melancholicke are purged by diuers wayes, some of which are ordinary, familiar and accustomed to Nature; others extraordinary and not so conuenient.

Some passages ordinarie, some extraordinary.

The ordinary passages prepared for the expurgation of Flegme are the pallate and the nosethrils; but the palate especially, because the Nostrils were primarily appointed for smelling. Anatomy teaches vs that out of the third Ventricle of the Braine there is a conspicuous passage to the inward basis thereof, in whose extremity there appeareth a small portion of the thin Membrane which is first broader then groweth narrower like a Tunnell which the Grecians call *πυελὸν ἢ χοάνην*. The Latines *Peluis* and *infundibulum*, *The Basen or Tunnell*, through which the Flegmatick humor is by litle and little transcolated as it were through an *Hyppocras* bagge. This wateriſh humor is receiued by a flegmaticke Glandule like a sponge, and afterward distilleth by degrees through the holes of the Wedge-bone into the pallat and mouth. But if at any time (which is not vnvsuall) the vpper Ventricles of the Braine grow full of a mucous slime it droppeth through the processes which are like to the nipples of a womans paps into the *Os Cribri forme*, or spongy bone, and so into the Nosethrils.

The waies of the Phlegme.

The bilious excrements are continually purged by the ears. Some say that therefore the bilious excrements are throwne out by the eares that the heate and siccitie thereof might keepe the bones of the eares dry and so more fit to receiue and report the sound. But the Phlegmatick excrements are purged by the mouth and nosethrils, that those open passages by that humidity might be kept from drying vp. These therefore are the ordinary channels and most familiar to nature by which she purgeth the excrements of the Brain? There are also other extraordinarie waies by which the brain oppressed or surcharged with abundance of humor exonerateth it self. Such are the eyes, the Spinal Marrow and the Nerues from whence commeth the Palsie. There is also sometime a fall of humors through the Veines and arteries into the *Parotidas* that is the Glandules behinde the eares. But these are not the peculiar excrements of the brain, that is, of the Marrowy substance and of the Ventricles, but rather of the vessels as Veines and Arteries from whence proceed tumors of the glandules, inflammations likewise of the eyes and of the eares.

The Bilious by the eares.

The extraordinary passages.

Now these excrements in a temperate Braine are moderate in their substance, quantity, quality & time of excretion. In the substance, because they are neither to thick nor to fluid; in their quantity because they do not abound; in their quality because they are neither salt nor sharpe; in the time of excretion when they are auoyded after concoction.

By what passages the superfluities of the afterbrain & the fourth ventricle are auoided.

The remaineth one scruple to bee resolued, that is, by what wayes the superfluities of the *Cerebellum* and of the fourth ventricle are purged. We say for answer that the excrements of the *Cerebellum* and of the fourth ventricle are very fewe; as well because of the hardnesse of the *Cerebellum*, as also beecause in the fourth ventricle are contained most subtle, pure and well purged spirits, and therefore those few superfluities are easily dissipated. But the braine it selfe being in quantity very great and of temper very moyste heapeth vp aboundance of superfluities which stand in neede of conspicuous passages by which they should be auoyded.

QVEST.

QVEST. XIII. *Of the number and vse of the Ventricles.*

Of the number of the ventricles.

IN the Hiſtory of the Ventricles of the braine there are many things controuerted which offer themſelues to our conſideration; and firſt of all the Anatomiſts doe differ concerning their number. *Galen* determineth that there are foure, two *ſuperior* which he calleth *anterior ventricles*; the middle which is a common cauity and the backward. *Auicen* numbreth but three; the vpper, the middle and the hindmoſt; eſteeming the vpper two for one, becauſe they haue the ſame figure, magnitude, ſcite, ſtructure and vſe. *Arantius* addeth two others vnder theſe which he nameth from the figure *Hippochampi*, but I thinke that they are parts of the vpper ventricles, which indeed are ſo large that in common diſſections ſcarſe their third part is ſhewne. *Varolius* cutting the braine after a newe manner ſayth there are but two; but becauſe we haue at large made mention of his opinion in the Hiſtory foregoing, we will not here weary our Reader with itteration thereof, but referre him thither for further ſatisfaction.

Of the vſe of the ventricles

Concerning the vſe of the ventricles, *Veſalius* taxeth *Galen* about the vſe of the vppermoſt two; becauſe hee ſayth that they are the organs of ſmelling and that out of theſe by certain proceſſes the phlegme is trãſcolated into the ſpongie bones. VVe anſwere for *Galen*, that the *anterior* ventricles are therfore called the Organs of ſmelling, becauſe vnto the are odours brought of which alſo they iudge. Beſide, what ſhould hinder that the flegme (if the brain abound therewith) ſhould not be tranſported from them by thoſe proceſſes into the ſpongie bones, ſeeing we find that ſomtimes (as in the *Apoplexie*) the phlegme is diffuſed through the whole body of the braine; and ſometimes falleth into the nerues and the ſpinall marrow as in the Palſie? It will bee obiected that the ſence of ſmelling would be extinguiſhed if the phlegme ſhould bee tranſcolated by theſe proceſſes: I anſwere, that ſometimes when the Fluxe is continuall and the humour very aboundant the ſmelling is loſt, not ſo much by reaſon of the obſtruction of the proceſſes, as becauſe the holes of the bone are intercluded.

Galen redeemed.

Obiection.

Solution.

The opinion of ſome new writers.

Some new writers there are who thinke that the *anterior* ventricles were not appoynted for the preparation and concoction of the ſpirits, as well becauſe they are the receptacles of excrements, as alſo becauſe the Animal ſpirits did not ſtand in neede of any ſenſible cauity. But *Galen* anſweteth, that Nature hath prepared them to ſerue both turnes; like as through the ſpongie bone odours doe aſcend and ſuperfluities or excrements deſcend. As therefore thoſe things which are auoyded euery day by the pallat and the noſthrils do neyther hinder the Taſte nor the Smell if they bee moderate: ſo it is in the excrements of the braine.

QVEST. XIIII. *Which of the ventricles are moſt excellent.*

Of the prehe-minence of the ventricles of the braim.

COncerning the excellency or *ſuperiority* of the ventricles of the brain ſome different places in *Galen* are to be reconciled. It is commonly receiued that among all the partes of the braine the ventricles are moſt excellent, not becauſe they are particular ſeates of the Prineipall faculties, but becauſe in them the Animall ſpirits are generated. That teacheth *Galen* in the third Chapter of his 7. Booke *de Placitis Hip: & Plato.* If, ſayth he, you cut the braine any way the creature will not looſe ſence and motion before the wound pierce vnto ſome of the ventricle. But whereas there are foure ventricles it may be demanded which of them is moſt noble.

The vpper ventricles are the baſeſt.

Galen teacheth that the vpper ventricles are the baſeſt; In his 8. Booke *de vſu partium &* the 10. Chapter. In his 7. *de placitis*; and in his Commentary vppon the 18. Aphoriſme of the ſeuenth Section, by the example of a young man of *Smyrna* a Citty of *Ionia*, who being wounded into one of the vpper ventricles yet eſcaped with life. Concerning the third and fourth ventricles *Galen* ſeemeth to differ from himſelfe; for in the fift Chapter of his third Booke *de locis affectis* he yeeldeth the prerogatiue to the fourth ventricle. The Animall ſpirit ſayth he, is contayned in the ventricles of the braine, eſpecially in the hindermoſt, although the middlemoſt is not to be contemned: which is as much as if hee had ſayed the middlemoſt is not the nobleſt. For wee are perſwaded by many reaſons to eſteeme this aboue the two vpper. In the third Chapter of his 7. Book *de placitis*; A wound in the hindmoſt ventricle doth moſt of all offend the creature; In the ſecond place the wound of the middle ventricle; but leaſt of all if it be in the two vpper: the ſame thing may bee ſayed of

The 4. the nobleſt.

According to *Galen*.

ſec-

sections or bruises of the head. And these authorities of *Galen* are seconded by reason; for it is a perpetuall truth in the body of a man, that by how much the cauity is greater, by so much it is the baser. The fourth ventricle is of all the rest the least and the narrowest, and containeth the Animall spirit sincere defœcated and exquisitely purged: the other do onely prepare the spirit, and therefore the hindmost ventricle is the most noble.

Yet *Galen* in many places seemeth to say the contrary, as for instance in the 7 chapter of his third booke *de locis affectis*, and in the second chapter of his fourth booke, he preferreth the third ventricle. If saith he, at any time the whole fore-part of the braine bee affected, those things which concerne the vpper ventricle are drawne into consent, and the action of discourse is vitiated; where, by the vpper ventricle he vnderstandeth the third or the middle: but why, I am not able to giue a reason. But if discourse bee seated in the middle ventricle, then is it the most noble. In the last chapter of his third booke *de placitis* expounding the fable which faineth Minerua to be borne out of the toppe of *Iupiters* head. Therfore, sayth he, they faigne her to be borne out of the top, because there vnder is seated the middle ventricle which is the principall of the braine and the originall of wisedome. *Galen* seemeth to say the contrary.

Moreouer the wonderfull structure of the third ventricle is an euident argument of the excellency thereof, as also because the wounds of the *Occipitium* are lesse dangerous then those of the *Sinciput* or fore-part of the head. So saith *Hippocrates* in his booke *de vulneribus capitis*. *More escape death that are wounded in the hinder parts of their heads then in the fore-part.* The reason.

You shall reconcile *Galen* if you say, that when he auoucheth the fourth ventricle to be the most noble, then he speaketh according to his owne iudgement: but when he preferreth the third he speaketh according to the opinion of other men, especially of *Herophylus*. For *Galen* did not attribute or assigne to the principall faculties particular mansions or habitations in the braine as we haue heeretofore prooued. *Galen* reconciled.

Againe, vpon a wound in the *Occipitium* or nowle of the head, the fourth ventricle is seldome offended, because there is much flesh and the thicknesse and hardnesse of the bone to resist the violence of the blow, whereas the bones of the *Sinciput* or fore-part are much more slender and weake.

In the whole history of the head I do not finde that *Galen* seemeth so much to wander out of the way as in the description of the *Rete mirabile* or *wonderfull Net*, for this in a man is so small that a good eye can hardly discerne it. I like rather, saith my Author, to call the *Plexus Choroides* (which is manifest and obuious to euery eye in the vpper ventricles of the braine) *Rete mirabile* or the *Wonderfull Net*, as also some of the new Writers haue done: for in it the vitall spirit is attenuated and the Animall getteth a certaine rudiment. And thus are we come to an end of the Controuersies concerning the Braine especially the substance thereof. Now let vs proceed to the second part of the head which is called the Face and so to the Senses. The error of *Galen* in the wonderfull Net.

The End of the seauenth Booke vvith the Controuersies thereto belonging.

THE EIGHTH BOOKE,

Of the Senſes and their Inſtruments, *as alſo of the Voyce.*

The Præface,

ALthough in the former Booke wee have made mention of the Inſtruments of the Senſes when we deſcribed the Coniugations of the Sinnewes of the Brain, yet becauſe there are many other parts in the Head ſet apart for their vſe, wherein the glorious wiſedome of our Creator dooth moſt manifeſtly ſhine and in the preſeruation whereof wee are deepely intereſſed, I haue thought good to appropriate this Eight Booke vnto the Hiſtory of the Senſes. Now in euery Senſe there is a Matter and a Forme. The Forme is the Faculty which is a thing yſſuing from the Soule and differing in Name not in Nature as it informeth this or that Matter which is the Inſtrument. The

The eyes.

firſt of the Senſes is the Eye the moſt precious part of the body; and they are two, that if one ſhould miſcarry the other might ſupply the neceſsity of Nature. They are ſet like Centinels or Scout-watches in the top of the Towre, whence they may diſcerne the farther off if any thing approach either hurtfull or behoouefull that we may apply our ſelues to it or auoyde it.

Galen is of opinion that the Head was placed vppermoſt in the bodie for the Eyes ſake, becauſe the Opticke Nerues ſtood in neede to bee very ſnort. For their ſecurity they are ſcituated in Caues and fenced about with diuers Muniments. Aboue them hang a round arched brow to beare off and caſt ouer what might fall from the Head, and betwixt them runnes the Noſe as a ſtrong wal, vnder them the bones of the Cheeke ſtand out, and at their ſide the hard bones of the Temples.

They are immediately couered with ſoft lids that they might not impeach the delicacy of the inſtrument; the vppermoſt are mooueable and verie nimble which do ſhut vp the pupils as well in reſt to refreſh them, as alſo when any outward iniury is ready to annoie them; the lowermoſt are immooueable or at leaſt mooued inſenſibly. Theſe liddes are againe bearded with haires whereby and wherein ſmall bodies or Motes which happly in their approach are not diſcerned might be intercepted.

The Eyes themſelues haue many Muſcles allowed them whereby they are mooued euery way, vpward and downward, to the right and to the left and round: they are alſo by a Muſcle ſuſteined and kept ſtable or firmed whereby the ſenſe is more certaine. Diuers Coats they haue wherewith they are couered, the firſt called *Adnata*, the ſecond *Cornea*, the third *Vuea*, the fourth *Aranea*. There are alſo three Humours, the firſt *Watery*, the ſecond *Glaſſy* and the third *Chriſtalline* which is the chiefe Organe of the ſight, and is aſſiſted by the other parts aboue mentioned. The eye indeede ſeeth with the Chriſtalline humor, but it ſeeth perfectly and more accompliſhedlye with the whole Organ or Inſtrument.

mẽt. The obiect of this ſenſe are thoſe colors which are in the ſuperficies of other bodies.

Next followeth the Eare, the Inſtrument whereby the Soule diſcerneth of all manner of ſounds and voyees. The chiefe part of this Organ is a thin and ſubtle aire bredde in the eare and ſeated within the cauity therof; to which aire the ends of the Nerues of hearing which come from the Braine doe attaine: and as the Opticke Nerue encompaſſeth the Criſtalline humour, ſo this nerue of Hearing is thought to encompaſſe the *In-bred Ayre* and ſpirit, and ſo the ſociety growes betweene the inſtrument of the Senſe and the inward principle of Senſation. Before this Aire is a Membrane ſtretched which we cal the *Drum* ſupported and eſtabliſhed with three Bones, the ſmalleſt of the whole body, but none formed with more curious Art; the firſt is called the *Hammer*, the ſecond the *Anuile*, the third the *Stirrop*. Many men haue laboured to aſsigne to each of theſe their proper vſes and how they conferre to the ſenſe of Hearing, but truth to ſay, their diſcourſes do rather feed then fill the minds of their Readers. The Eares.

God hath reſerued many ſecrets in mans body to himſelfe, whereof wee iuſtlie thinke this is one; yet we know that they ſuſtaine the Membrane of the Tympane againſt which the repreſentation of the ſound or voice is beaten and communicated to the inbred Aire. Theſe ſounds are admitted to the Inſtrumẽt by the hole of hearing, a hard & dry entrance full of embowed Meanders and Convolutions, leſt the outward aer falling or ruſhing ſuddenly vpon the *Drum* ſhould endanger the breaking therof. Without the Eare there ſtandeth a griſtly ſubſtance which partly defendeth the hole of Hearing that nothing fall into it, partly catcheth and ſtaieth the ſound that it paſſe not by.

The third Senſe is that of Smelling, whoſe Inſtrument doth not yſſue out of the Scull in thoſe creatures which do reſpire, but is conteined within the ſubſtance of the brain: whẽce it followeth that theſe 5. are called outward ſenſes, not ſo much becauſe they appear outwardly, but rather becauſe their proper organs doe receiue the ſpecies or repreſentations of outward things. The inſtrument therefore of ſmelling is a paire of productions iſſuing out of the forward Ventricles of the Braine, in which the faculty of ſmelling reſiding doeth comprehend the odors of things which together with the aer are drawne in thorough the paſſages of the noſe, which is rayſed higher in the face of a man then of other creatures, as well for beauty, as becauſe the Braine of a man being large and therfore yeelding, abundance of excrements might ther-through be better clenſed. This noſe is diuided in the middeſt by a griſtly ſubſtance, aſwell to breake and diuide the outward aire which in a great part is drawn in this way to be conueyed into the ſharp arteries & ſo to the lungs; as alſo to diſperſe the parts of the obiect of this ſenſe, that being ſo diuided it might equally inſinuate it ſelfe through the ſmall holes of the ſpongy bone to both the productions which determine on either ſide. The Noſe.

The fourth Senſe is the Taſt, the Forme whereof is ſeated in thoſe Nerues which attaine vnto the tongue and pallat aſsiſted by the ſpongy fleſh of the tongue it ſelfe. For when any ſauoury quality or affection imparted to a humor or iuice is applyed vnto the tongue; it ſtirreth vp the taſte, and preſently the image or ſpecies of that ſauour is by the ſpirit reſiding in the Nerues conueied to the principall Senſator; and if it happen that the ſauour be repreſented to the Inſtrument in a hard or congealed body as ſalt, pepper or ſuch like, it cannot mooue the ſenſe before it be melted by the heate, or at leaſt haue communicated his affection vnto the moiſture of the mouth, and therfore it is that nothing can affect the taſte which cannot be diſſolued, neither is he whoſe tongue is torrified or parched with extraordinary heate a competentiudge of ſauors or Taſts. The Tongue.

As for the Touch which is the fift and laſt ſenſe; it is not conteined within any proper organ or inſtrument but equally diffuſed through the whole body, becauſe the neceſsity of Nature did euery where require the preſence thereof for the ſecurity of the life of the creature; and yet notwithſtanding it dooth not (as other ſenſes) receiue the impreſsion of all his owne proper obiects. For ſenſation is a paſsion: if therefore the Obiect bee of the ſame temper with the Inſtrument, the ſenſe is not affected therewith, becauſe it doth not ſuffer by that which is like vnto it; but all the other ſenſes do apprehend all thoſe qualities which do fall vnder them; for being all vnlike to the inſtruments they muſt needs be affected by them. But becauſe this ſenſe hath no particular inſtrument in the head, we ſhall only intreate of it by the way in this place; ſomwhat we haue ſpoken of it before in our diſcourſe of the skin, and more we ſhal haue occaſion to ſay in the booke of the Ioynts and the Veſſels. Wherefore we deſcend vnto our Hiſtory. The ſenſe of Touching.

CHAP. I. *Of the other part of the head which is called the Face, together with the veſſels and muſcles thereof.*

HAuing gone through that part of the Head which is couered with a hairy ſcalſe and therefore by *Ariſtotle* in the 7 chapter of his 1. book *de hiſtoria Animalium* called τριχωδὴς; it remaineth that we proceed vnto the other part which is without hayre called in man πρόσωπον; which name it ſeemeth to haue receiued from the thing it ſelfe, ſaith the Philoſopher in the firſt chapter of his third book *de partibus Animalium*, becauſe a man πρόσωθεν ὄπωπε, that is, *looketh forward*; for of all creatures onely man goeth vpright and looketh directly forward. The *Latines* call it *Facies*, in the comely conformation and Beauty whereof the elegancy of the humane nature doth moſt appeare. It is alſo called *Vultus a voluntatis iudicio*, becauſe it bewraieth the diſpoſition of the will, and is eſpecially changed according to the variety thereof. We call it the Face or the countenance.

The names of the face.

The parts of the face.

The parts therefore of the Face are two: the vpper is properly called μέτωπον *Fronis ferendo*, becauſe it beareth in it the Paſsions of the minde, wee call it the Forehead whoſe loweſt parts are the eye browes. The ſecond and lower part of the Face beginneth at the eye-browes and reacheth to the bottome of the Chinne, in which there are many parts. Both theſe parts of the face haue alſo ſome parts conteining & ſome conteined. The containing parts are common or proper: common as the cuticle or ſcarfe-skin & the skin it ſelfe; which in this face, in the fingers ends, in the Yarde and the Cod is moſt thin. This skin in the Cheekes for the moſt part looketh red becauſe of the affluence of blood from the vtter branch of the externall Iugular veine; which is diſſeminated betwixt it and the fleſhy membrane. This skin is furniſhed with hayres; about the eyes for their ſecurity; about the mouth in men as an argument of their virility and a peculiar beauty of thatſex; for in a woman thoſe hayres are an eſpeciall deformity. Hence alſo (ſaith *Galen* in the 14 chap. of his 11 book *de vſu partium*) a man becommeth more venerable, eſpecially if whé he be grown to a ripe age the haires alſo do plentifully compaſſe his mouth on euery ſide, for which cauſe alſo nature hath left the Cheekes and the Noſe bare and without haire.

The skinne.

The hayres.

This skin of the face is diuerſly perforated for the eyes, the eares, the noſthrils and the mouth; partly that the ſenſible obiects might haue the freer acceſſe; partly to intromit ayre and nouriſhment and to auoide excrements. And theſe perforations if their actions bee alwayes required are alwayes open. As the noſtrhils for reſpiration; the eares for hearing becauſe theſe two were alwaies neceſſary. As for thoſe whoſe functions were not ſo indefinent, eſpecially in the time of ſleepe and for the auoyding iminent dangers, thoſe perforations I ſay, for more ſecurity may be ſhut as the eyes and the mouth.

The perforations of the face.

Their vſe.

The fat of the face is very little and that that is, is about the Cheekes.

The fat.

The fleſhy membrane which in the reſt of the body is almoſt wholy neruous, in the forehead is fleſhy and muſculous; ſo cloſe ioyned to the skin that it can hardly be ſeparated there-from. And it is red becauſe of the muſcles of the face which grow vnto it. Betwixt this fleſhy membrane and the skin the veines before ſpoken of do runne. where alſo are many glandules diſperſed, as vnder the rootes of the eares in which the diſeaſe is bred that we call *Parotis*, as alſo betwixt the lower Iaw & the inferior part of the Cheeks where thoſe Tumors ariſe which we cal *Scropuhlæ* or the Kings euill.

The fleſhy membrane.

The veſſels and the glandules.

The proper containing parts are muſcles, bones and griſtles which make the frame of the face it ſelfe. The muſcles are, of the forehead, of the eye-browes, of the eye-lids, of the noſthrils, ſometimes alſo of the eares, of the lips, of the lower Iaw, and of the Cheekes. The bones are, the forehead-bone, the ſixe bones of the eyes, three of the Noſe, ſixe of the mouth, that is to ſay, two of the vpper Iaw, and two of the nether Iaw, and as many of the Palate. The Griſtles are, of the eares & the noſe which are diuerſly ioyned with the bones.

The proper containing parts.

The parts contained in the face are the ſeates of the foure ſences; whoſe organs either it containeth as it doth thoſe which haue no place within the skull, or elſe it prepareth a way for them that lye hid within the Scull.

The parts contained.

Theſe Organes of the ſenſes are the Eyes, the Eares, the Noſe and the Mouth, wherein are contained the Tongue and the Throttle which are the inſtruments of the taſte & the voyce. And indeede becauſe the Organs of the ſenſes are placed in the face, it is truely called the Image of the minde, for as *Laurentius* ſaith truely, in the eye-browes dwels

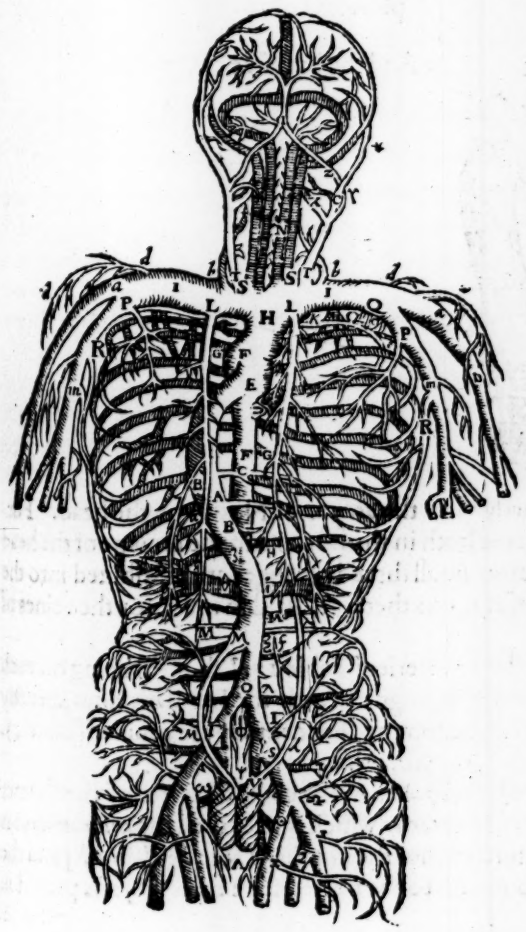
pride

pride, in the Cheekes ſhamefaſtneſſe, in the Chinne maieſty, in the Forehead wiſedome; finally, in the whole countenance beauty and honeſty. But to ſpeake more like a Phyſitian, in the Face doe appeare the manifeſt ſignes of life and death, and therefore *Hippocrates* in his Prognoſtiques commands the Phyſitian firſt of all to take viewe of the ſickmans face, whither his countenance bee like that it was in his health, or whether it be much changed in colour, figure and magnitude. How the mind ſhineth in the Face.

But before we come to the particular handling of the Organes of the Senſes, it ſhall not be amiſſe to giue you in this place a light view of the Veſſels of the Face and of the Muſcles which mooue the skin of the Head. The Veſſels therefore which are deriued through the face are Veines and Arteries. The Veynes are called Iugulars, whereof one is internall, [Tab.6.lib.6. SS] of whoſe diſtribution we haue ſpoken in the eight chapter of the precedent Booke. Another externall [Tab.6.lib.6.TT] which ariſeth out of the vpper part of the *Subclavian* branch, and aſcendeth on the ſides of the neck vnder the chin yeelding ſurcles to all the outward parts of the Necke, the Head and the Face on his owne ſide. But for the moſt part vnder the roote of the eare, [Tab.6.lib.6. V] it is diuided into an vtter braunch [Y] and an inner. [X] The inner branch reacheth vnto the muſcles of the mouth, the chops, and the bone *Hyois* as before is ſaide. The vtter creeping along the skin and the Muſcles and skin of the head, beeing vnder the eare ſupported with Glandules, is parted into two branches, whereof one bending vnto the foreſide of the face [Tab.6.lib.6. Z] attaineth vnto the Noſe and the Cheekes, and in the middle of the forehead is ioyned with a braunch of the other ſide, and maketh the fore-heade Veine which in ſome caſes wee vſe to open. [Tab.6.lib.6. *a*] The other braunch paſſeth by the ſide and ſprinkleth his branches partlie Prediction by the Face. The veſſelles of the ſame. The Veines.

Table 6. ſheweth the trunke and branches of the hollow veine as they are diſſeminated through all the three Regions of the body.

TABVLA VI. Lib. VI.



Q. The double Scapularie, or the veynes of the ſhoulder-blade.

RR. The Lower Cheſt-veine.

SS. The internall Iugular Veine.

TT. The externall Iugular Veynes.

V. The externall Iugular Veine diuided into two vnder the roote of the eare.

X. The inner branch thereof.

Y. The outer branch thereof.

Z. A branch proceeding from the vtter Veyne nexte aboue named, to the Face.

a. The forehead Veine.

e. A branch creeping vppe the Temples.

* A ſurcle reaching to the Nowle or backeſide of the head.

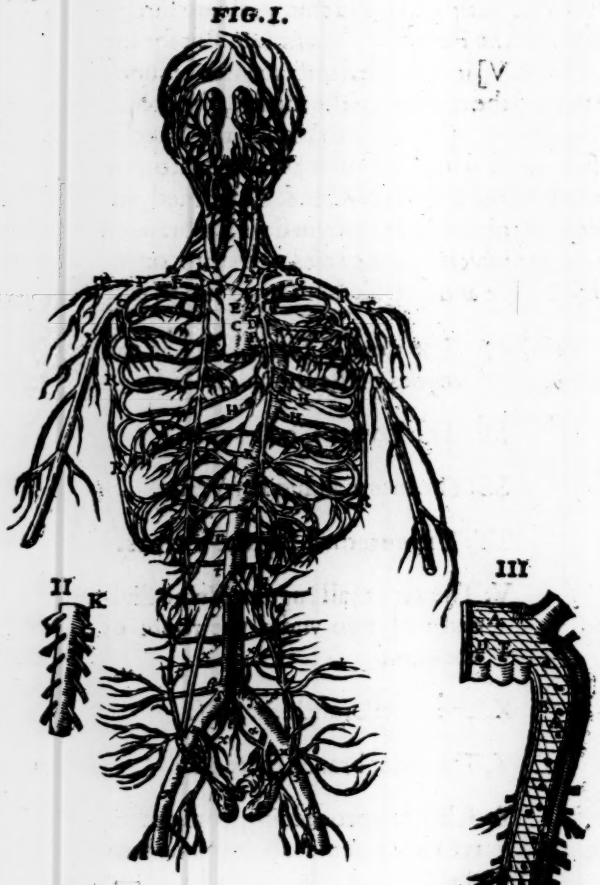
Table 13. Fig. 1. ſheweth the trunke of the great Artery, together with his branches as they are diſſeminated through the three bellies or Regions of the body.

The ſecond Figure ſheweth a portion of the Arterie as it is on the backſide, from whence it ſendeth branches to the diſtances betwixt the lower ribbes.

The third Figure ſheweth a portion of the great artery, where it yſſueth out of the heart it is here ſhewed open: & by that meanes we may better perceiue his Coates and Fibres.

TABVLA. XIII.

FIG. I.



TT. The Artery called *Humeraria.*

V V. the remainder of the Axillarie Artery reaching to the armes.

X Y. the right and left *Carotis* or the ſleepy Arteries.

e e. The coniunction of the Mamary with the Epigaſtricke Arteries.

ff. The diuiſion of the ſleepy Arteries at the *chops.*

g. The externall branch.

h. The internall branch which is deriued to the throttle, the chops and the tongue.

i. This at the Baſis of the Skull is diſtributed into two branches.

l. the diſtribution of the branch *g* vnto the Cheeks and the Muſcles of the face.

m. The diſtribution of the braunch *g* vnder the roote of the eare.

n. The ſame branch creeping vp the Temples.

o And the backſide of the eare.

vnto the Temples [Table 6. Lib. 6. *a*] partly vnto the *occiput* or Nowle of the head. Furthermore the branches of this *exterior* veine both in the face and in the crowne of the head are diuerſly mingled, from which certaine ſmall threddy ſtringes are diſtributed into the ſeames of the Skull and the manifold perforations thereof. And ſo much for the veines of the face.

The arteries of the face

The arteries called *Carotides* or the ſleepy arteries [Table 13. Lib. 6. *xy*] being on each ſide one, aſcendeth vp on the ſides of the necke, togither with the Iugular veines, directly vnto the head, and when they come vnto the chops or Fauces they are deuided [table 13. lib. 6. *ff*] into an exterior branch [*g*] and an interior [*h*].

Of the diſtribution of the *interior* we haue ſpoken in the eight Chapter of the former Booke. Now concerning the *exterior*. The *exterior* which is leſſe then the *interior* and is ſeated without the Fauces reacheth his furcles vnto the cheeks [Table 13. Lib. 6. *l*] and the muſcles of the face; afterward when it commeth to the roote of the eares [*m*] it is parted in twaine.

twaine. One of them creepeth to the backside of the eare at[°] from which two arteries do vnder the eare passe into the lower iaw, and according to the length thereof are dispersed vnto the rootes of all the lower teeth: but another part ysslueth at the hole which is in the chinne, and so creepeth along the neather lip. The other artery of the by-partition at[P] creepeth vp the temples and the forehead and is consumed in the muscles of the Feae. And so much of the vessels.

The Skin of the head is in many men mouable, but of the forehead in all men; not onely by the benefite of the fleshy membrane, which degenerateth into a musculous substance hauing right fibres, but also by the help of two muscles; assured so to be, both by the course of their fibres as also by their motions which appeare in these after the manner of other muscles and not like the motion of the fleshy membrane. These are scituated in the forehead [Table 6. figure 1.*] and doe arise aboue where the hayre determines; sometimes as high as the crowny seame neare the Temporall muscles; the right at the right and the left at the left Temple; (where the fleshy membrane cleaueth so close to the *Pericranium* or skul-skinne and the Skull it selfe, that it is altogether immouable: So that the forehead and the Eye-browes are mooued when the membrane is at rest) and toward the common seame which distinguisheth the bones of the head from those of the vpper iaw are implanted with right fibres aboue the eyes and the nose into the skinne at the browes as at the parts which are to be moued. The muscles of the forehead.

I sayed these fibres were right and not oblique as some haue thought: and here Chyrurgions must obserue that in opening Apostemations in that place they make not their incitions ouerthwart as the wrinckles of the skinne doe goe, but according to the right fibres. A good note for Chyrurgions.

These two muscles are a little disioyned in the middest, and that is the reason why the top of the forehead is not moued. Vpon this coniunction some haue thought them to be but one muscle. Against whome wee shall further dispute in the proper place where wee treate of these in our booke of muscles. There are also other muscles which draw the skinne of the head backward, but those belong not to this place. Why the top of the forehead is not moued.

Now we proceed vnto the Organs of the Sences.

CHAP. II. *Of the Eye and parts thereof.*

WEe sayd before that the habitations or residences of foure of the Sences were contayned in the face.

The fist externall Sence, which is the Sence of Touching is dispersed through the whole body & hath no proper seat in the face, all the rest haue. For the head being the seat of the Animall faculties and the habitacle of the reasonable Soule; it was also necessary that the Sences, which as *Hippocrates* in his Booke *de morbo sacro* or of the Falling sickneſſe, sayth, are the messengers and interpreters of the Soule, should also haue their residence in the head. Why 5. sences

These outward Sences are fiue as there are fiue simple bodies, the Heauen and the foure Elements. VVherefore according to the *Platonists*, the Sight answereth in proportion to the *Element of Starres* whose obiect is shining. The obiect of the Smel is fiery, and therefore it is sayd that *fragrantia* are *flagrantia*. The obiect of the Hearing is ayrie: the obiect of the Taste is watery, and of the Touch earthy. But amongest these the Sight is the principall, which with hearing makes a mannes life much more happy, albeit without the Tast no man can be so well nourished. For those who either by Nature or by Accident are blinde do account themselues therein miserable; for as the Sunne (saith *Galen* in the tenth Chapter of his third Booke *de vsu partium*) in the great world, so is the Eye in the body of a creature; and therefore *Hesichius* calleth them πύλας ἡλίου *Solis portæ*, The dores of the Sun; and therefore we will first intreat of the Eyes, as also because amongest all the nerues the Opticke nerues haue the first place. How the sences answere the elements. *Galen.* *Hesychius.*

The Grecians call the Eye ὀφθαλμὸς *quasi* ὠτὸς θάλαμος, because it is the couch or bed out of which the Sight shineth. And therefore the Eyes are called by others θύρα, because from them φῶς that is the light proceedeth. The Latins as *Varro* and *Lactantius* call them *oculi, ab occulendo vel occultando* from hiding, because they are couered and hidden within their Liddes. The names of the Eyes.

These Eyes are the Organs of the faculty of Seeing, which we vse (sayth *Galen* in the fist Chapter of his 8. Book *de vsu partium*) as spies, not only to auoyd those things which wold of-

offend vs, and to leade vs vnto that which is profitable, which vse is common to vs with bruite beasts, but especially that by those things which are visible we may take consideration of the omnipotency of the inuisible God. Hence it is that *Plato* said wel, that if we wanted our Eyes wee should bee ignorant of that excellent order which Nature hath established in the frame of the world and of our own bodies. *Aristotle* addeth that the Science or exquisite knowledge of all things is exceeding much furthered by the eyes. And therfore *Galen* calleth them diuine members: Seeing therefore their necessity is so great it is no wonder that God the Creator made them after so excellent a manner as it were a curious modell to manifest his Maiesty and wisedome.

Their excellency.

They are scituated in the head as in the highest and best defensed place of the body, immediately vnder the forehead as Scoutwatches: for as watchmen are placed in high standings and turrets that they may further of discerne whether any enemies be approching or lye in ambush, so the eyes are set aloft to foresee and giue warning of any danger that may be toward vs. *Galen* and *Auicen* haue conceiued that the head was especially made for the vse of the eyes, their reason is, because the optick nerues being very soft, could not safely be placed farre from them. They are seated in the forepart of the head, whereof *Galen* in the first chapter of his tenth booke *de vsu partium* rendreth a reason, because saith hee the Instruments of this sense do require soft nerues which could not bee produced from the *Cerebellum* or After-braine as being much harder then the braine it selfe.

Their scituation.

The reason thereof.

Moreouer being placed before, they are directly opposed to their obiects, and we moue forward, neyther can we discerne eyther on the side, or behind vs, vnlesse wee turne our heads about. They are seated within bony cauities which *Pollux* calleth κοιλοτητας or Orbes, & that for security; haply also because the spirits might be lesse disipated.

They are in number two, (as also are the other instruments of the senses) moued together and at once with the same motion, that the sight might be more perfect; for if one of them had beene lifted vppe and the other depressed, then euery obiect howsoeuer would haue appeared double: for it was necessary that the *axes* or *diameters* that is, the imaginary lines of the pointed obiects should determine in one and the same place: and this ioynt action of the eyes is assisted by the coniūction of the motiue sinewes in their originall as we haue already declared. Obserue further with *Aristotle* in the 17 Probleme of the 10 Section. That amongst all Creatures a mans eies stand neerest together for his proportion. Their figure in a man is round and spherical [table 2, fig. 3, and 4] but in other creatures they are not perfectly round, but eyther oblique or depressed, [tab. 2 sig. 5.] and no maruell seeing the whole figure and fashion of a mans body differs so much from other creatures. But if you consider them together with their muscles which grow to their back-sides, then is their figure turbinated like a sugar-loafe. [tab. 1, fig. 4, and 9] The reason why they were made round, was partly that they might be more capatious because they were to containe many parts of great vse. Againe, that figure is the strongest and lesse subiect to offence by outward iniuries. Finally, their roundnes makes their motion more nimble, to which end also they are smooth & slippery that we might command our sight euery way at our pleasure and vpon the suddaine. Wherefore the Maisters of the Opticks say that because of the orbicular or round figure of the eye, the beames from which side soeuer they come are broken at the Perpendicular, that is to say, they arriue directly in the center of the eye. Their magnitude is proportionable to the magnitude of the body and their owne vse. And heere we are to consider two kindes of parts; the one of those which are disposed about the eyes for their defence: the other, whereof the eye is compounded. For defence Nature hath compassed them with bones which frame their Orbe, and beside these they are walled, aboue with eye browes, before which lids and in eyther place fenced with hayres and the skin. For first of all the brim of the eye-lids stand as a wall of defence with their hayres shot out that no smal motes or other annoyances might fall into the eyes when they are open. Then the lids themselues, that closing together they might shut vp the eye if any greater body or more violent offence should be offered thereunto. Furthermore, to defend them from violence, aboue they are secured by the eye-browes, below by the Cheekes, at the great angle with the Nose, at the lesser by the production of the yoke bone, and so if any greater body do rush against the eye, it is receiued by one of these, the eye which is in the middest remaineth vnoffended. The motion also of the skin as wel that of the forehead as also that of the cheeks is a great security vnto the eie, for the skin being contract the eye is as it were drawn inward, & the same again extēded openeth thē wide. The orbe of the eye is round, [ta. 2, li. 7 fi. 6, at ◦ ta. 12, fi. 8, betwixt ˣ and ˣ] that

that therein the eye might be better rowled: long, becauſe of the muſcles whereby the eye ismooued, and compaſſed with a *Perioſtium* or thin membrane. It is formed of the bones of the head and of the vpper iaw. But *Aquapendens* addeth alſo the ſpongy bone which we call *Ethmoides*. The bones of the head which make the orbe of the Eye, are the foreheade bone and the wedge-bone, whence it is that in theſe dennes of the Eyes there be many ſutures and holes to be found. The forehead bone whoſe outward ſeat or table is ſmooth, maketh the vpper Arch of this rooſe: and where the tables are ioyned againe, there in the place of the Eye-browes it buncheth outward [Table 3. lib. 7. figure 8.[ARX]] and ſo defendeth the Eye. The wedge-bone is in the backe part of the hollowneſſe or cauity of the orbe, where it is perforated with foure holes. [table 3. lib. 7. figure 8. neare [PO]] The bones of the vpper iaw which help to make the orbe of the Eye are; the firſt which maketh his outward eminence below. [table 3. lib. 7. figure 8. r] The ſecond and the third [table 3. lib. 7. figure 8. ΘΘ] are in the inſide, very thin bones, becauſe the protuberation or ſwelling of the noſe is alſo a defence in that place. The fourth bone of the vpper iaw lendeth a part to the framing of this orbe where the cheekes riſe vp into a ſwelling prominence [table 3. lib. 7. fig. 8. neare i.] The bones of it.

The ſutures or ſeames in the bones of the iaw are three; one at each angle or corner, the third in the lower ſide of the orbe: the ſutures of the ſpongie bone are two, both at the great angle. Finally, there are other ſutures betwixt the wedge-bone and the forehead-bone. And vpon theſe ſutures are the *Pericranium*, the lower oblique muſcle and the pully ſuſpended. The Sutures of it.

The holes in the orbe are three and thoſe very large; one in the hindmoſt part which is round, made for the tranſmiſsion of the opticke nerue: the ſecond is in the lower part of the cauity of the orbe, and is a long rift through which the nerue which mooueth the eye together with ſome veines and arteries are deriued vnto the Eyes and their muſcles. The third is at the inward angle & perforated into the bones of the noſe, through which holes ſometimes a part of the teares do yſſue. The holes 3.

In theſe orbs of the Eye doe ariſe on either ſide two *ſinus* or circles, which *Ariſtotle* in his firſt Booke *de Hiſtoria Animalium*, calleth common parts of the vpper and neather Eye-lid, becauſe they are made of both the Liddes extended out in length. Theſe circles the Grecians call κανθοὶ ἀπὸ τῦ κνήθεσθαι, that is, from a Sence of Itching, becauſe in them oftentimes by reaſon of the teares or of ſome other humour we finde a notable itching. The angles or corners,

The Latines call them *anguli oculorum*, we the corners of the Eyes, wherein the teares & whatſoeuer yſſueth from the Eyes is gathered together. The outward angle or corner toward the Temples is called *Canthus minor* or *externus*. The other inward to the noſe *Canthus maior & internus*. [Table 1. figure 1. and 6.[c] ſheweth the greater corner and[d] the leſſe] *Pollux* calleth the greater angle ῥαντὴρ the waterer, and *Heſychius* πηγὴ or the fountain, becauſe from thence the teares doe yſſue. Their names.

But theſe names I take to be fitter for the orbe it ſelfe then for the corner of the Eye, for in each angle in the very extremities or ends of the ridge of the eye-lid both aboue and below there are two holes [Table 1. fig. 4. 7. 8.[mn]] which in the leſſer corner can hardly be perceiued when a man is aliue, but after death they are not at all conſpicuous; but in the inward and greater angle theſe holes are larger and eaſie to be perceiued if we marke them well eſpecially in women; whence haply it is that they haue teares at command. But in the eye of an Oxe euen after he is dead they may eaſily be demonſtrated [tab. 1. fig. 4.[mn] fig. 7. and 8. they are only expreſſed in the greater corner at [n].] The holes of the eies.

Theſe holes are called by *Fallopius* in his obſeruations *Puncta Lachrymalia*, as alſo by *Platerus*, becauſe thorough them the teares doe diſtill, eſpecially by the greater, which Nature vſeth rather and oftner then the leſſe, becauſe the ſcite thereof is more declining. Although there is a more open way for them through the noſe, the bones of the vpper Iaw being notably perforated in the top of the noſe, which holes haue certaine paſſages, which vnder the caruncle are vnited into a common boſome ending in the cauity of the noſe, and this cauity is properly called πηγὴ that is, the fountaine. *Puncta lachrymalia.*

But this Bone becauſe it is of it ſelfe thinne and hollowed, beſide by the paſſage or canale before ſpoken of is ſometime exulcerated by the Acrimony either of other humours or of the teares; which ſayeth the Philoſopher in the 35. Probleme of the firſt Section, are ſoft and like vnto ſweate: and this kinde of Vlcer is called *Fiſtula Lachrymalis*, wherein if you preſſe the inner corner of the eie, you ſhal find a *Sanious* or mattery ſubſtance to iſſue. The diſeaſe called *Fiſtula Lachrymalis.*

This

This matter is also oftentimes thinner, of which *Hippocrates* speaketh in his Booke *De Prisca Medicina* where he saith, that oftentimes there is a Flux of humors euen to the eie whose acrimony exulcerateth the eye-lids, and the partes vnder them it gnaweth assunder, yea sometimes it eateth thorough the coate that compasseth the Aple of the eye. That therefore this exulceration might be preuented, Nature hath set at the inner angle a Caruncle or glandulous flesh which the Grecians call ἐγκάνθιδα or ἐπικάνθιδα, although *Ægineta* giueth it that name onely when it is growne aboue the due proportion. *Galen* in the eleuenth chapter of his tenth booke *de vsu partium*, calleth it σῶμα σαρκῶδες, *Corpus Carneum*, *The Fleshy body.* [Tab.1. fig.7. 8r] This Caruncle was made to defend the bone from the sharpenesse of the humors. Moreouer, it serueth for a couering whereby the perforations which we saide before were made through the bone, are as it were stopped with a sponge, through which the excrements of the eye may soke into the nose, but cannot returne againe to offend the face, or to make vs alwaies weepe. Wherefore, those whom we call Oculists, that is, such as professe and intend the cure of the eies; must take heed that they do not vse such sharp Medicines as may coliquate or dissolue this Caruncle. For we haue often seen that Medicines applied to the eyes haue through these holes past into the nose, and so haue beene cast out either by emunction or by the mouth. But because we are come to make mention of the teares, it shall not be amisse a litle to stand vpon the nature and manner of the auoyding of them.

The wisedom of Nature.

A Caution for Oculists.

Plato, *Aristotle*, and *Theophrastus* do thinke the teares are a kinde of sweate, or at least much like thereto. *Aquapendens* his conceite how agreeable it is to reason let others iudge, sure it is very quaint and witty, his words are these. The Tears are an excrement of the third concoction in the eye, proceeding from the nourishment of the Glassye and Cristaline humors; which excrement is engendred of blood as of his proper matter, yet is that blood diuersly altred by the temper of the eye. For from these humors of the eies there is a double excrement separated; one thicke, another thin. The thicke excrement is that blacke slime which cleaueth to the Coats called *Vuea* and *Choroides*. Another thin which are the tears to which a whayie or serous humidity may be added. Thus far *Aquapendens*.

Diuers opinions cõcerning teares.

Aquapendens. opinion.

But *Bauhine* is of opinion that these teares are the excrements of the Braine, whome happly it will be more safe to follow. Now whereas in euery concoction there is a double excrement separated, one thin another thicke. In this concoction which is celebrated in the Braine, the thicker excrement which is viscid and crasse Flegme is spit out of the mouth from the pallate or else descendeth by the nose. The thinner excrement is partly euaporated insensibly, partly it commeth away verie manifestly, and sometimes mixed also with a more crasse excrement: now it moysteneth the tongue & the mouth to make the speech freeer, and to helpe mastication or chawing of the meate. Sometimes it is transported to the whole face, but especially to the cheekes, to the temples and the eares; which may bee prooued by wounds inflicted vpon those places, which though they seeme to be healed, do yet notwithstanding for two or three moneths together euery day yeeld a great quantity of pure and watերish humour, issuing by the hole that is left in the woud, which no art is able to consolidate or make vp; which obseruation we confesse we haue from that notable Anatomist & Chirurgion *Aquapendens*.

Bauhines opinion.

That moisture which is transmitted to the muskles is the matter of the teares, to wit, that whay which together with the blood is transported vnto the braine to bee ἰχωματῶν τροφῆς. *The vehicle of the nourishment*, that by the helpe thereof the blood might bee able to passe through the smal vessels which are dispersed through the substance of the brain, which whay beeing not fit for nourishment, in the nourishing of the braine is percolated through his thin substance, as the whay is separated from the milke. This moisture is gathered together in the bony orbe of the eye, which is indeede of so great capacity that the fourth part thereof is not filled by the muskles and nerues of the eye. It remaineth therefore after the manner of other excrements a conuenient time in that cauitie, and is sucked or drunk vp partly by the fat, partly by the Glandules which are of a rare and spongy substance. The reason why Nature detained these excrements in the orb of the eie was to moisten the Muscles, which because of their continuall motion were not onely in danger to be ouer-heated, but also to be exiccated and dried vppe; vnlesse they had beene moistened and refrigerated by this matter of the teares which swimmeth in a manner about the fat and Muscles of the eye. And this vse hath the moisture if it bee moderate

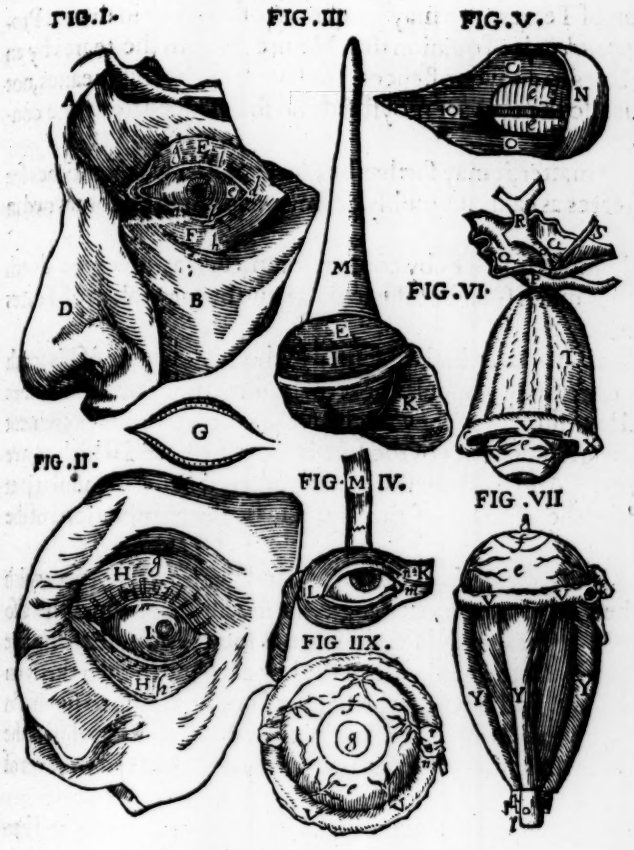
TABVLA.I.



A 1, The forehead bone.
B 2, The bone of the vpper Iaw.
C 1, The yoke bone.
D 1, The Noſe.
E 1,3, the vpper eye-lid.
F 1,3, the lower eye-lid.
a a 1, the Tarſus or little griſtle wherein the haires grow.
b b 1, the haires of the eye-lid.
c 1,6, the greater Canthus or corner of the eye.
d 1,6, the leſſer Canthus or corner of the eye.
e 1,5,6,7,8. the membrane called Adnata which in the 6,7, and 8, fig. is intertexed or wouen with veines.
f 7,8, The Rainebow called Iris.
g 1, 2, The hollownes of the vpper eye-lid and in the 7 and 8 the apple of the eye.
h 1,2, the vnder cauity in the lower eye-lid.
m n 4.7,8, Two holes in the greater angle or corner of the eye.
o 7. the opticke nerue.
p q 7, the *Pia meninx* at *p* and the thicke at *q* which do inueſt the optick nerue.
r 7,8, A Caruncle or little fleſh in the interior corner.
G, The Cartilages or griſtles of the eie-lids called *Tarſi.*
H H 2, The orbicular or round muſcle of the eye-lid without the skin.
I 2, the hornie coate containing the Rainebow and the apple of the eye.
K 3,4, the orbicular muſcle of the eye-lid ſet alone, but in the 4. it is deſcribed cõpaſsing the whole eye-lidde which *Veſalius* diuided into two.
L 4, In this place *Veſalius* ſet the ſecond.
M 3,4, the right muſcle of the eye-lid ſet alone
N 5, The outward part of the eye-lid.
O O O 5, the concauous and interior face of the eye-lid.
P 6, the interior portion of the wedge-bone where-through the opticke nerue doth paſſe. Q Q, 6, A part of the thicke membrane or *Meninx.* R 6, the concurſe or meeting of the opticke nerues. S 6, The mouing nerue of the eye. T 6, the fat betweene the muſcles, V 6,7,8, A part of the coate called Adnata ſtretched vnder the eye-lids. X 6, Membranes going from the Scull-skin to the Tarſus or griſtle of the eye-lids, Y 7, the muſcles of the eye on the one ſide.

moderate, for if it be immoderate and detained in the eye, it hindereth the motion of the muſcles: wherefore Nature being heerein very prouident and wiſe hath framed and prepared two wayes for the expurgation thereof. One by the corners of the eyes, another by perforations into the bones of the Noſe as we ſaide euen now. For if the teares ſhould perpetually drop out at the eyes they would haue deformed the face, as wee perceiue by thoſe who are troubled with the diſeaſe before named caled *Fiſtula lachrymalis* or the dropping Fiſtule,

The mouing of teares, how many wayes. by expreſſion

Nature therefore ſtuddying to preſerue the beauty and comelineſſe of the face as alſo the cleerenesſe of the ſight hath prouided meanes to moue them by expreſsion or by dilation and attraction. By expreſsion the teares are mooued eyther when we rub our eyes, or by the coldneſſe of the ayre, or by the winde, or by ſome griefe of minde and weeping fit; at which times they drop out like plentifull ſweate, or rather like a bubling ſtreame through thoſe holes which we ſaide before were formed in the terminations of the brims of the eye-lids: for at ſuch times the muſcles of the face and of the adiacent parts doe con-

tract

tract themselues sometimes with wayling and mourning sometimes without; sometimes the Respiration being cut off in the middest with a sobbing stay and the voyce broken about the top of the *Larynx*, yea sometimes quite intercepted: and thus is this matter of the teares moued by Expression.

2 by dilatation. By dilatation it is drawne out sometimes by heat, often by laughter, sometimes by the Sunne, for sayeth *Hippocrates* in his Booke *de videndi acie*, the Eye being not able to resist a bright obiect, calleth out the matter of the teares to succour it, which also in the conflict is heated. Anger also and a sharpe Ague doe by dilatation prouoke and cal out the matter of the teares.

Hippocrates.

And in such an Ague sayth *Hippocrates* in his first Book *Epidemion*, if other signes be not mortall, teares so appearing doe foreshew a Fluxe of bloud by the nose. That these are the very causes of the profusion of Teares, we may gather out of *Aristotle* in the 13. Probleme of the fift Section. *Aquapendens* is of opinion that Nature purgeth the teares by an expulsiue faculty giuen to the Eyes to auoyde offences; for sayeth he, by this meanes, not onely Nature is vnburdned but also the eyes are moystned and so defended from the contaction of cold and heate.

Aristotle.

Obiection. But not to contend about this matter, it may further be obiected that we oftentimes see at once so great a quantity of teares as cannot possibly be imagined could be contayned in the orbe of the eye.

Solution. I answere, that this serous humour followes by consequution, euen as phlegme doeth fall out of the braine. And thus much shall be sufficient to haue beene spoken of Teares and the manner of their euacution.

The glādules of the eye. At either angle of the Eies, as also *Galen* hath obserued in the 11. Chapter of his tenth Booke *de vsu partium*, are placed certaine glandules or kernels, sometimes two sometimes more: that with their rare and laxe substance they might sucke vp that serous excrement of the braine, by which the outward superficies of the Eye is moystned, and which as wee sayed is the matter of the teares. And this moysture thus gathered in the glandules is at conuenient times euacuated by the corners of the Eye and by the terminations of the brimmes of the lids.

Fallopius. *Fallopius* in his obseruations sayth, that there is but one Glandule in each corner, which is found in the vpper part of the Eye neare the vtter angle, the inuention of which he also attributeth to himselfe.

Their vse, Moreouer these glandules do serue as soft pillowes that the Eye might not be offended in his motion at the hardnesse of the bone. And in men this is on this manner: But in bruite beastes it is otherwise; which it shall not be amisse to signifie in the fauour of young beginners and Practitioners in Anatomy, who doe often dissect the eyes of Oxen and Sheepe to make them more perfect when they doe come to the eyes of Men.

the same in an Oxe. In an Oxe Eye therefore is found another glandule in the inner corner, callous and harder then that in a man, which should seeme to be there scituated because of the membrane with which they wincke, which membrane is most like to that we call the Naile of the eye, very thinne and like the horny coate, or something of the Nature of a gristle. This Nayle or membrane of which *Aristotle* speaketh in the 12. Chapter of his second Booke *de Historia Animalium*, is moued with voluntary motion to the outward angle and couereth the eie

A membrane in the eye of an Oxe, euen when the lids are open. For about the roote of this callous glandule there cleaueth a strong membrane, whose vse haply is, that while the Skin is drawne to the opposite angle that glandulous body should be streatched or bent like the horne of a bow, and when the skinne is remitted, returne backe and draw it into his proper angle. And truely this membrane is drawne to the opposite angle by a double cord, the one is aboue, the other below lurking vnder the coate of the eye which we call *Adnata*, and arising from a certaine muscle scituated in the vtter angle, which muscle *Fallopius* accounteth to bee a part of that muscle which draweth the whole eye outward. And thus much concerning the parts of the orbe of the Eye.

CHAP. III. *Of the Eye-browes and Eye-lids.*

The eie brows THe Eye-browes with *Aristotle* in the ninth Chapter of his first Booke *de Historia Animalium* we referre vnto the Eyes. They are called in Latine *Supercilia* because they be *super cilium*, that is, aboue the haires of the Eye-lids. *Hippocrates* in his Booke *de locis in homine*, as also the rest of the Grecians after him call them ὀφρύες. They are, sayth *Rufus*, hayrie extremities of the forehead, or haires

haires that grow aboue the eies which are diſtinguiſhed vnder the forehead on either ſide. Theſe eie-browes are compounded of skinne, fleſhy fibres produced from the muſcles of the forehead, fat and haires. The skin is thick and hard, thick the better to defend the eyes, hard, that the haires might neither be too many, nor grow into too great a length, for euen as ſaith *Galen* in a marriſh and weeping ground no graſſe is brought forth neither yet in a ſquallid and hot ſoile, ſo when the skinne is either too dry or too moyſte the haire cannot grow. Whereof they are compounded. A fit compariſon out of *Galen*.

Theſe haires are called by the Phyſitians as *Pollux* witneſſeth τυλοὶ, & are bred with vs whē we firſt come into the world, as alſo are the haires of the eie-lids, whence it was that the Egyptian Prieſts who vſed to ſhaue all their haire did notwithſtanding ſuffer theſe to grow. And although theſe haires are of an equall length, number and thicknes, yet are they not right but grow crooked and oblique, bowing after the roundnes of the eie, that they might the better auert and turne aſide whatſoeuer ſhall fall toward it. If they had bin too ſhort, too few, or too thinne, they would not ſo well haue defended the eies. Againe, if they had been too long or too briſtly they would haue bin an impediment to the ſight. In ſome men ſaith *Ariſtotle* when they grow old they encreaſe vnto ſuch length that they ſtand in neede to be cut, the reaſon whereof he rendreth in the 15. Chapter of his 2. Booke *de part. animalium*; becauſe they are placed in the coniuncton of the bones which in old age are looſed, and ſo a greater quantity of vapour yſſueth from their diſiunction. Why they grow long in old men. But howe the diſpoſition of the minde may be obſerued from theſe hayres according to *Ariſtotle* in the 9. Chapter of his firſt booke *de Hiſtoria animalium*, and how the antients (as *Cicero* reporteth in his oration for *Roſcius*, and in the firſt booke of his Offices) placed a part of the Soule in the eie-browes *Bauhine* hath well declared in his booke *de partibus externis*, to whome we refer him that deſireth further ſatisfaction.

The middle place betwixt the eye-browes which for the moſt part is without hayres is called by *Ruffus* and *Pollux* μεσόφρυον, in which place *Straton* the Philoſopher as *Plutarch* reporteth placed the ſeat or principall reſidence of the Soule.

Theſe Eye-browes although they be drawne vp by the muſcles of the forehead; yet in ſome men (ſayth *Iulius Placentinus* out of whome we haue taken their figure) there are two muſcles found in the *occipitium* or nowle of the head [Table 4. fig. 1. C the other in the ſecond figure at aa is retracted aboue the noſe like the pannicle inuerted] which leading the skinne of the head backward doe alſo draw the eye-browes with it, as we ſhall ſhew in the fourth Table figu. 2. c, where alſo wee will exhibit the orbicular muſcle which draweth the eye-browes downward. How they are moued,

Concerning the vſe of the Eie-browes, the Philoſopher in the 15. Chapter of his ſecond Booke *de partibus Animal.* ſayeth; that as well theſe as the haires of the eye-lids were created for defēce. The eie-browes are as a penthouſe to caſt of the humors that fall from aboue: yea ſaith *Galen* in the 14. chap. of his 11. booke *de vſu part*: they are like a wall of defence which receiueth the firſt brunt of the irruption of any thing that would offend the eies: which vſe alſo *Cicero* maketh mention of in his 2. booke *de Natura Deorum*.

It was not ſufficient that the eyes ſhould be walled about with bones, and as it were included or ſhut vp in bony dens, and defended by the eye-browes from thoſe things which ſhould fall from the forehead, becauſe their forepart was expoſed vnto many dangers. For being by nature made ſoft and tender for the more facile and eaſie reception of the ſpecies or formes of things outwardly directed vnto them, they muſt needes by diuers wayes be in danger of offence. Wherefore Nature very prouidently hath fenced them with ligaments and lids, wherewith as with leafe-dores not only the eies themſelues but their whole orbes are ſhut vp, and thence it is that thoſe creatures the outward skin or coate of whoſe eyes is notably hard, as *Galen* well obſerued in his booke *de inſtrumento olfactus*, haue no eye-lids at all, becauſe their eies were not ſo ſubiect to danger. Of the eie-lids, What creatures want eie-lids.

Theſe leafe-gates of the eies are called by the Grecians βλέφαρα *quaſi* τῆ βλάπτεσθαι ἐπιφέρα, that is, *The Coates of the Sight*: Thence alſo they are not vnfitly called by a Poet ὀμματόφυλλα, that is, *The leaues of the Eye*. *Cicero* calleth them *Palpebræ*, either becauſe in their ſudden and frequent motions, they doe *Palpitare* that is tremble, or elſe becauſe they are often ſubiect to a trembling weaknes. *Pliny* cals them *Genæ*; *Feſtus Cilia*. The names of the eie-lids,

The eie-lids are two in each eie, for it is cut through the middeſt and diuided into an vpper & a lower, for in both the corners they are manifeſtly cōtinuated, the vpper [ta. 1 fi. 1. & 3.]

in a man is much more moouable then the lower, which by ſome is thought to bee immoouable of it ſelfe and onely mooued by the motion of the cheeks as *Archangelus* conceiueth. So *Galen* ſeemeth to ſay in the ninth chapter of his tenth booke *de vſu partium*, but more plainely in the tenth Chapter and in his fourth Booke *De Locis Affectis*, vvith whom alſo *Veſalius* conſenteth & *Lawrentius* yeeldeth a reaſon, for, ſaith he, what neede was there that the lower eye-lid ſhould bee mooueable ſeeing by the motion of the vpper downward the eye is cloſed to his bottome, and by the motion thereof vpward the eie againe is ſufficiently opened? But *Platerus* thinketh that the lower eye-lid is mooued ſomething vpward when we ſhut our eyes. And with him *Bauhine* is of opinion that the lower lid is mooued by a Muſcle, although his motion be farre more weak and leſſe conſpicuous then that of the vpper. For if both the eye-lids were made for the vſe of the eies then was it neceſſarie that either the vpper ſhould mooue downward, or the lower vpward, or the one meete the other. Now wee finde by Diſſection that in the lower lidde there is a ſemicircular Muſcle as well as in the vpper, and in a creature aliue if we marke the eie well, we ſhall perceiue the lower lid to mooue though not ſo manifeſtlie as the vpper; but in Birds (as *Ariſtotle* obſerued in the 13. chapter of his 2. booke *De Partibus Animalium*) the lower eie-lid is onely mooued.

Whither the lower lid bee mooueable.

The lower lid is onlie moue able in Birds.

Neither could ſo ſodaine and quick motions come from the vpper lid alone, becauſe the motion downward would haue needed a longer time then was fit for ſo quicke diſpatch, and therefore they ſooner meete if they ioyne to aſsiſt one another. But the vpper lid in a man and in thoſe creatures in whome the lower is not ſo ſwiftly mooued is larger, becauſe it was to bee let downe much further then the lower was to be raiſed vp. On the contrary in birds the lower lid is larger then the vpper.

The lower eie lid why leſſe.

The lower lid [Tab. 1. fig. 1, 3. ff] is much leſſe then the vpper, and if it had not beene ſo little falling vpon it ſelfe it would haue beene corrugated, wrinckled or relaxed and haue falne from the eye. And which is more, the eye would haue become bleared, wateriſh and ill affected. Beſide many things might haue gathered therein which would haue hardly bene gotten out. Wherefore it was much fitter that this lower lid ſhould be but little and ſit cloſe to the eye, that ſo whatſoeuer getteth within it might bee better preſſed out. We therefore reſolue according to our ſenſe, that both lids are moued, the vpper downward and the lower vpwarde that they might meete one with another. But becauſe the lower is by much the leſſe, therfore is his motion weaker and more obſcure, as the motion of the vpper is more euident becauſe it is the larger.

Whereof the eie-lidder are compounded.

Theſe eye-lids are compounded of skinne, the fleſhie Membrane, a coat, Muſcles, their brim, and the haire. Wherefore their ſubſtance is partly ſoft, partly harde. Soft as it is Membranous and Muſculous, hard as it is griſtly: for if (ſaith *Galen* in the ſixte chapter of his tenth booke *de vſu partium*) it had beene onelie fleſhie and ſoft, becauſe they are firſt expoſed to danger, they would haue beene ſooner offended then the hornie coate of the eie, yea they would eaſily haue falne, become rugous and would not ſo equallie haue beene ſtretched ouer all the parts of the eie.

On the contrary, if they had beene hard and bonie, they would not ſo eaſilye haue beene mooued, neither could the hornie Membrane or coate haue touched them without danger of offence.

The reaſon of their compoſition

It was therefore fit that the eie-lid ſhould bee made of ſuch a ſubſtance as ſhould both eaſilie bee mooued and yet not offend the eie by contaction.

The thinnes of their skin & membranes

The skinne of the eie-lid is the thinneſt almoſt of the whole bodie altogether without fat, leaſt thereby their motion ſhould be hindred. Their fleſhie Membrane is ſo thinne that together with their Muſcles it is ſcarſe ſo thicke as the Membrane alone which is vnder the skinne in other parts, ſo that the orbicular Muſcles ſeeme to bee nothing elſe then the fleſhie Membrane diſtinguiſhed with ſmall Fleſhie Fibres, as *Galen* ſaith of it in the ninth chapter of his tenth booke *De vſu partium*. And by reaſon of this tenuitie or thinneſſe of the Membrane and skinne of the eie-lids. *Ariſtotle* ſaith, that their skinne is without Fleſh, and therefore if it bee wounded will not ioyne together againe as it happeneth in the Prepuce or fore-skinne of the yard.

Ariſtotle.

The inner Membrane [Table 1. figure 5. ee] which is produced from the *Pericranium* is exceeding thinne and light. Thinner and lighter then the *Pericranium* it ſelfe, polliſhed alſo that it ſhould not hurt the ſight of the eye which moueth immediatly againſt it. This membrane

brane being produced into a length answerable to the length of the eye-liddes as also into their skin, doth make in the vpper & lower part a round angle, and becommeth duplicated or doubled, to which duplication is ānexed a certaine gristly substance harder then a membrane, which they cal τάρσος, we called it before the brim of the eie-lid, & this substance shutteth vp & comprehendeth the duplication before spoken off. The vpper part of this membrane compasseth and as it were subdivideth the inner superficies of both the lids. The other coūereth the *exterior* roundnesse of the eye aboue the tendons of the muscles as farre as to the *Iris*, and produceth that coate of the eye which is called *Adnata* (for to it it is continued) [table 1. fig. 7. v v] which louingly ioyneth the lid vnto the eye.

The reason of the thinnes of the lids.

Now the thinnesse and the lightnesse of the membranes was necessary to further the swiftnesse and suddennesse of the motion of the eye-liddes; for if they had beene heauy they could neither haue been moued suddenly nor often, which two things were very necessary: the frequency of the motion to meet with whatsoeuer might affect the eye, the celerity to take away all impediments of the sight. It is no wonder therefore if Nature made the body of the eye-lids very thin, smooth and soft, that so they might be more nimble and prompt to moue at our pleasure.

The motions of the eie-lids

The motions of both the eye-lids are vpward and downward, there is also another motion made by them both together which is circular, wherein both the eye-lids are gathered together. For it was necessary that the eyes should bee opened and shut, for if they had beene alwayes couered with the lid, they could neuer haue receiued the images of their obiects, and if they had alwayes remayned open, neither had they been free from ourward injuries, and beside they would soone haue grown weake by reason of the perpetuall dissipation of their inward light; wherefore it was of necessity they should bee opened and shut. And therefore *Aristotle* in the 13. Chapter of his 2. Booke *de partibus Animalium*, writeth that this motion is by an instinct of Nature not after the guidance of our will, and that the Eyes by that instinct doe winke at any thing that falleth toward them; but this conceit *Galen* reprehendeth in the ninth chapter of his tenth Booke *de vsu partium*, where hee sayeth, There are some Sophisters when they could not finde out either the muscles which moue the Eye-lids or the reason of their motion, they became so impudent as to deny that their motion depended vppon our will: but affirmed that it was Naturall like the motion of the arteries and of the heart, esteeming it better to teach a lye then to confesse their owne ignorance

The necessity thereof.

Galen.

The motion double or of 2 kinds.

Voluntarie.

Constrained.

Aristotle excused.

But this motion although it be voluntary yet it is partly free partly constrayned: the free motion is for the couering and custody of the eyes, if haply any thing should bee troublesome vnto them, as too strong a light, smoake, dust, a blow or whatsoeuer might happen vnto them from without. That motion we call Constrayned which is stirred vp by a corporiall affection or serueth thereunto, and this motion is exceeding suddain and swift, and therefore for the most part we do not marke it; whence it was that *Aristotle* rather thought it Naturall then voluntary; for example; when wee haue long time held our eyes open although there be nothing to offend them, yet we are constrained to close them vp or at lest to wincke, and that oftner and more suddainly in winter then in Summer, when the winde blowes then when the ayre is quiet. It may bee becausse the eye is not able to endure the touch of the externall ayre, becausse of the tendons of his muscles, which are of exquisite Sense and exposed almost naked to the aire, hauing nothing vpon them but the thin membrane called *adnata*; beside it hath beene often obserued that the Chrystaline humour it selfe hath bin condensed or thickned with cold to the great detriment of the sight. Wherfore that the eye might not be hindered at all from seeing, nor from preseruation of it selfe when neede doth require: the eye-lids were necessarily made with a sudden and swift motion to shut them and open them againe.

How cold offends the eye.

The muscles of the eie-lids

Diuers opinions concerning them.

Now these motions are performed by two muscles commonly called the muscles of the Eie-lids: but *Archangelus* calleth them *musculi ocularii*. Neither do others agree in the number of these museles, for *Galen* and the ancients as also *Vesalius* and *Siluius* doe make two, diuiding the orbicular muscle of which wee shall speake anon into two, whereof one, say they, lifteth the eie-lid vp the other depresseth it or moueth it downward. But the truth is, there is onely one muscle which shutteth the vpper lid according to *Columbus*, *Fallopius* and *Archangelus*. *Platerus*, *Bauhine* and *Aquapendens* affirme that that muscle contracteth both the lids. *Laurentius* indeede maketh this muscle double, and yet hee saith that both of them shutte the vpper lid. Hence it followeth that *Galen*, *Vesalius* and *Siluius* were igno-

rant of the muſcle that openeth the eye, which *Fallopius*, *Platerus*, *Bauhine*, *Laurentius* & *Aquapendens* will haue to be but one, but *Columbus* and *Archangelus* ſay there are two, the one of them we acknowledge, but that which they call the ſecond wee ſay mooueth the eye round.

The motions therefore of the eye-lids are performed by two muſcles, the one *right* [tab.1,ᴹ tab.2,ᵝ] of which *Galen*, *Veſalius* and *Siluius* were ignorant; and *Fallopius* aſcribeth the inuention thereof to himſelfe. This *right* muſcle which lifteth vp the vpper lid is ſcituated within the cauity of the bones; in the vpper part of the Orbe, aboue but neare the muſcle that lifteth vp the eye it ſelfe, to which alſo it is in figure very like and fleſhy, but leſſe and hath his originall from the ſame beginning with the other muſcles that moue the eye: to witt backward at the hole of the opticke nerue. This muſcle is extended directly to the vpper eye-lid, and is inſerted with a broad tendon to the extremity of the lid, which we ſaid was griſtly and called *Tarſus*, and contracting his fibres inward draweth the lid vpward; the lower lid of his owne accord falleth downward into his owne place, and ſo the eye is opened.

The ſecond muſcle which is ſemicircular [tab.6,fig.1,ᶜ ᵃ tab.1,ᵃ] or orbicular is called by *Columbus*, *Falopius*, *Platerus* and *Archangelus* the firſt muſcle of the eye lid, but *Veſalius* and *Siluius* following *Galen* haue diuided it into an vpper and a lower part. The vpper part, ſay they, lifteth the lid vpward, the lower mooueth it downeward. *Fallopius* in his obſeruations confeſſeth that he was a long time of the ſame opinion with *Galen* and *Veſalius*; but in the yeare 1553, took knowledge of his own error being admoniſhed partly by *Oribaſius* in his booke *de diſſectione muſculorum* in what place he epitomiſeth the 29 chap. of *Galens* booke; partly by diſſecting the eye of a fiſh, called *Phoca*, which we call a Seale, which fiſh moueth both his eye-lids. *Laurentius* diuideth it into two, and calleth them the two muſcles which ſhut the lids, whereof one, ſaith he, ariſeth from the inward angle and compaſſeth the whole courſe of the hayres. The other ariſeth from the ſame angle and the roote of the Noſe, and is inſerted into the *Tarſus* or brimme of the lid. But in the deſcription hereof we will rather follow *Bauhine* who ſaith, That this orbicular muſcle is ſeated betwixt the fleſhye membrane and that which is produced from the *Pericranium* or Scull-skin. It is membranous and very thin or ſlender, yet a little increaſed by certaine circular and fleſhy fibres which it borroweth from the fleſhy membrane, and ſo ſtandeth halfe round in eyther lid. It ariſeth with a ſharpe beginning at the roote of the Noſe in the great and inward angle of the lower lid, where the common ſuture is betwixt the head & the vpper law, from thence it proceedeth all along the latitude or bredth of the lower lid and is inſtantly inlarged and returned to the outward angle toward the vpper part of the Orbe, and paſsing on by the vpper lid is inſerted with a ſharpe determination into the vpper ſide of the inner angle, and ſo maketh an exact circle compaſsing the outward circumference of both the lids; yet *Falopius* in his inſtitutions excepteth the inner part at the great angle, from which it is prohibited that it might not be altogether circular.

Bauhines deſcription of them.

The vſe of this orbicular muſcle is that being drawne toward his originall, it might at one and the ſame time moue the vpper eye-lid downeward, and the lower vpward, & ſo ioyne them and binde them both together. And that this is ſo it appeareth as well by the continuity of the fibres in the circumference and in the angle, as alſo by the motion of the ſame angle eſpecially if it bee a little more conſtrayned, ſo as wee muſt needes winke ſome thing withall, for then it is perceiued manifeſtly both by the ſight and by the touch. For nothing can be ſtrictly drawne together and made to touch one another vnleſſe ſome parts be drawne vpward and ſome downeward.

The vſe of the orbicular muſcle.

This muſcle in reſpect of his fibres which are continuall, is moſt truely ſaide to bee one, but in reſpect of the two lids may be called two ſemicircular muſcles, for being ſeparated they make each of them a halfe circle, but being ioyned they make the circle perfect.

How it is ſaid to be double.

This muſcle *Galen* knew, and in the 9 chapter of his 10 booke *de vſu partium* writeth that all the motions of the eye-lids are accompliſhed thereby. Hee diuideth it alſo into two, whereof one ſeated at the great angle draweth toward the noſe, the other (ſaith he) is ſeated at the leſſe angle and draweth toward the temples.

Moreouer in the traction of the firſt the lid is depreſſed; in the traction of the latter it is lifted vp, but becauſe the fibres of this muſcle are continuall through the whole lid it cannot be diuided.

Now

Now in the lower lid although it also be moued vpward and downeward, yet is there no Muscle which hath *right* motion, but onely this forenamed orbicular muscle which draweth it indeed vpward, but rather toward the inner angle or corner, as it wer to his beginning; as any man may perceiue by touching that part in himselfe, and yet I know that some thinke this motion proceedeth from the motion of the cheekes. How the lower Lid is moued vpward.

We determine therefore and conclude, that the motion of the eye-lids is accomplished by two muscles, one *right*, which being in the vpper lid eleuateth it, the other orbicular or round and is in both lids, which when it is stretched doth at the same time draw the lower lid vpwards and the vpper lid downward, and when there is need of a stronger contraction or closer shutting together, then also the orbicular muscle of the eye-browes (of which we made mention before) is drawne in to be assistant, like as when we would open the eye more staringly the muscles of the forehead doe much helpe vs. The conclusion cõcerning the Muscles of the eielids

He that would demonstrate these nice and curious Muscles must haue a very keene and small knife, wherewith he must separate the skin, in the meane time taking care that he doe not cut the Fibres of the Muscle, especially in the angles; then shall he separate the Muscle below at the *Tarsus* or brimme of the lidde, and aboue in the bottome of the eye-brow.

Columbus & *Archangelus* add a third Muscle which proceedeth say they out of the same place with the muscle lifting vp the eyelid, which third muscle is assistant vnto the former, because there is required more helpe to lift a heauie thing vpward then to draw it downeward. But we say that this third muscle of *Columbus* & *Archangelus* is indeed the next muscle of the eye. Of the gristle of the eielids called Tarsus.

We saide moreouer, that the substance of the eye-lids was cartilaginious or Gristlye, hauing respect vnto their extremities or brimmes into which certaine semi-circular cartilages [Tab. 1. *a a*] like the hornes of a halfe-moone, round, small and softe are inserted betwixt the skinne and the small Membrane which compassed the lid. These the Grecians call ταρσοὺς, but *Plinie* and the interpreter of *Galen* cal them *Cilia*. *Hippocrates* in his book *De Videndicaie* calleth this Cartilage γονδρῶν. Their Vses.

Their Vse beside that which wee haue remembred before, is to helpe the motion of the eye-lids; for because they strengthen and firme the thin Membranes and holde them distended that they are not corrugated or wrinkled in their motion, it becommeth that the shutting and opening of the eye is equall.

Galen in the ninth chapter of his tenth Booke *De vsu partium* remembreth another vse of them which is also approoued by *Vesalius* and *Falopius*, to wit, that the muscle which is in the vpper lid might haue a more firme and strong insertion. The same vse also it hath in respect of the haires of the eye-lids, which being established in so firme a substance doe remaine right and immooueable which otherwise would haue falne vpon the eyes. And therefore *Galen* in the seauenth chapter of his tenth booke *De vsu partium* maketh this the second vse of the *Tarsus*, wher he also affirmeth that it is perforated with many smal holes which notwithstanding *Platerus* denieth.

The haires of the eye-lids [Table. 1. fig. 1 *bb*] are called by *Hippocrates in Coacis* βλεφαρίδες, as also by *Aristotle*. *Pliny* calleth them *Palpebra a frequenti palpitatione*, because they are often rubbed. The later Anatomists call them *Cilia quod oculos celent*, because they hide the eyes. They are borne with vs into the world, as are also the haires of the eye-browes and disposed in an elegant order, keeping an equall magnitude and number, I say an equal magnitude: for sayeth *Galen* in the 14. chapter of his eleauenth Booke *de vsu partium*, if you add any thing to them, or take any thing from them you corrupt or vitiate their Vse, for if they bee fewer or slenderer there may some-thing fall thorough them to offend the Eye. The haires of the Eie lids. Their number. proportion. The wisedom of God.

Againe, if they bee thicker or grosser, they are no more a wall or defence to the eye, but a prison wherein the apple of the eye is hid and obscured, which of all the Instruments of our senses ha least th needе of such an obstacle, and therefore saith *Galen* in the place before quoted, our wise Creator hath laide vpon them a lawe of necessity to keepe continually an equall magnitude, because hee sawe it was most fit so to bee for the vse of that member for which they were ordained. The maner of their position.

But wheras (and this is *Galens* obseruation in the 7. chapter of his 10. booke *de vsu partium*) it was most conuenient that the haires of the eye-browes should couch or fal one vppon another, because they were made to receyue that which fell from the Head before it could

come vnto the eye: theſe haires of the eye-liddes hauing another vſe were made to ſtand ſtraight, becauſe they ſhould better hinder duſt, flies, or any ſuch like things from falling in to the eyes.

and reaſon thereof.

Againe, they ſtand not ſtreight vpward to the browes nor directly downward to the cheekes, neyther do they bend inward to the eye; for if they had ſtoode ſtreight vpwarde their vſe had beene forſeyred for which they were created, and if they had ſtoode directly downward or beene bent inwarde they would haue beene a great hinderance to the ſight by breaking the continuity of the viſible obiects. Notwithſtanding as the haires of the vpper lid are bent a little vpward, ſo are thoſe of the neather lid curued downward, for if they had ſtood ſtraight out they would haue caſt a ſhaddow vpon the eyes and hindered our looking vpward.

Their diſtãce.

In like manner there is a conuenient and as it were meaſured diſtance betwixt haire and haire: for if they had bin ſet one far from another many things might haue falne betweene them which now are intercepted, and if they had touched one another they would haue caſt too dull a ſhadow before the ſight. All which the wiſedome and prouidence of our great Creator hath by this excellent order and poſition auoyded. Theſe hai es doe neuer grow too long, neither do they euer fall, vnleſſe it be in extreame diſeaſes of that part, although *Ariſtotle* in the 11. chapter of his thirde Booke *De Hiſtoria Animal.* hath a conceite that the vſe of *Venus*, eſpeciallie if it bee to frequent will make them fall.

Their vſes.

Neither do theſe haires ſerue onely for ornament as ſome haue conceyued, but alſo to direct the viſible ſpirites and the beames which ſhoote foorth from the inner parts of the eye, for if they be falne away or retorted, a man can neyther ſee ſo directly forward, nor ſo farre off.

Againe, their often twinckling recreates the ſight, and breaketh alſo ſomewhat the brightneſſe of the obiect, as wel as they intercept thoſe things which otherwiſe would fal into the eye, being placed as a Net to catch any thing that would ruſh into them.

Their veſſels.

These eye-lids alſo haue veines from the Iugular veines; and Arteries from the *ſoporary* or ſleepy Arteies, Nerues alſo from the ſecond coniugation, all which veſſels do lead vnto them nourishment, heate and motion.

The bladders aboue and vnder the eyes.

That which hangeth ouer the vpper eye-lid [Tab. 1. Fig. 1. 2. g.] *Ruffus* the Epheſian calleth κεῖλος, that is, the *hollow*: and that which anſwereth thereto vnder the lower lid is called ὑπόκοιλον, or *vnder the hollow*. Tab. 1. fig. 1, 2. h.] And this vſeth to ſwell in the Dropſie, the greene ſickneſſe, a long fluxe of the Hæmorrhodes and of the courſes, ſometime alſo when the eyes begin to be bleared.

The vſes of the eye-lids. *Ariſtotle.*

It remaineth now that we add a word or two concerning the vſe of the eye-lids Although *Ariſtale* in the thirteenth Chapter of his ſecond Booke *de partibus Animalium* acknowledgeth no other vſe of theſe eye-lids, but onely to couer the eyes, and intercept thoſe things which would fall into them: and therefore ſaith that fiſhes haue no eye lids, becauſe they are alwayes in the water: nor ſhelly creatures becauſe the Mẽbrane of their eye is very hard, and beſide they ſtand deepe in their ſockets; yet we haue learned many other vſes of them which we will acquaint you with.

Varolius. The firſt vſe.

The firſt and chiefe vſe of the eye-lids therefore is, as *Varolius* well obſerueth, to cleanſe the hornie Mẽbrane from droſſe, for the ſight requireth an exact puritie in *medio diaphano* that is in his *tralucent meane*, otherwiſe we cannot ſee, eſpecially ſo diſtinctly, as appeareth in troubled water and ſmokie aire: wherefore becauſe the hornie coate by reaſon of the moiſture which ſweateth out of the glandule, as alſo by reaſon of the contraction of the outward aire is eaſily obtenebrated or darkned: the eye-lid was made compaſſed, that at once it might touch the whole eye, and therefore in opening the eye when the lid is lift vp, it ſweepeth and as it were poliſheth the whole horny coate or Membrane; and this is the reaſon why when we deſire to view a thing curiouſly we often winke with our eye-lids.

The ſecond.

The ſecond vſe of the lids is, that the viſible vertue might ſometimes be turned from the light, eſpecially in ſleepe that a man might take the better reſt; and hence it is that in thoſe creatures which haue no eye-lids, as Locuſts, Lobſters, Crabs, & ſuch like inſectiles nature hath prouided certaine cauities, wherein to in the time of their repoſe as into certaine chambers they receiue their whole eies and ſhoote them out againe when they looke abroade, for ſhee hath an eſpeciall care of this, that euery ſenſe ſhould be kept fit to performe his owne action.

And

And hence we may imagine the vnnaturall and cruell punishment which the *Carthagenians* inflicted vpon *M. Atilius Regulus*, whom in the first Punicke warre they had at vnawares surprized, who being by them sent to Rome (after he had before taken his Oath to returne) did in the Senate-house dissuade them from making exchange of captiues, wherefore when he returned they cut off his eye-lids and set him in the sunne vntill the brightnesse of the obiect ouer-came not onely the spirites of his Eyes, but also of his life.

A third vse of the eye-lids is to recreate the sight, least at one time too great a number of spirits should be exhausted; for if the eyes should be so long open as wee are awake, they would be wearied, and many things falling vpon their coates would offend them. Againe, if they be not quite shut vp they direct our sight, if we desire to take a true ayme at any thing which is somewhat farre off. The third vse

Finally, they serue to defend the soft eyes from the incursion of outward iniuries, because it is much better sometimes not to see at all, then by offering to see, suffer our eies to be offended. And thus much concerning the circumstances of the Eies. Now we proceede vnto the Eye it selfe.

CHAP. IIII. *Of the Fat & Muscles of the Eyes.*

THE parts whereof the Eye consisteth, are fiue Fat, Muscles, Vessels, Coats and Humors. The Fat which Anatomists do some of them call *Adeps*, som of them *Pinguedo*, is verie plentifull about the eyes [Tab. 1. Fig. 6. T] especially it is found in those spaces which are betwixt the Muscles and the Nerues. It is also more plentifull at the vpper Muscle, because that is greater and ordained for more frequent & strong motions. In like manner toward the lower side of the Orbe there is plentie of fat, which like a pillowe is laide vnder the Eyes, that with their weight they should not presse themselues vpon the bones. Againe, betwixt the Muscles and the globe of the eie there is aboundant fat, that when the Muscles worke the eie should not suffer compression. Finally, there is also fat found neere the Veines and Arteries, whereby the vessels are smeared ouer and their distention preuented in the motion of the eies. The parts whereof the eie is compounded. In what places of the eye the fat is found

The vse of the fat, in asmuch as it is warme, is to heate the eye which by nature is watrish and cold, and beside to defend it from the coldnesse of the outward aire. And that is the reason why we neuer feele any manifest coldnesse or stiffenesse in our eyes. Againe, the humidity of the fat doth moysten the Muscles, that they becõe not exiccated or dried vp in their often motions. The softnesse of the fat keepeth the eyes from being offended by the bones about them. The vnctuosity or oyly fatnesse maketh their motion swift and facile, and beside, when the Muscles are somewhat dried, because of their motion and as it were consumed, it affordeth Aliment vnto them. The vses of the fat.

The Muscles of the Eyes, although they belong to another place, namely to the Booke of the Muscles, yet because wee are desirous to absolue the History of the Senses in this present Booke wee will take liberty to varry something from our scope and set downe as perfect a description of them heere as we can. And that was the reason why before we were so large in describing the Muscles of the eye browes and eye-liddes, concerning all which we will spare our labour and yours when wee come to the History of the Muscles. Why the muscles of the eye are described in this place.

Because therefore our eyes were giuen vs as spies and scout-watches that wee might pursue things profitable and eschew that that is hurtfull, Nature made not the eyes immotable, for then they shoulde haue discerned onely that which is opposite vnto them, for so saith *Aristotle* in his second booke *De partibus Animalium* and the tenth chapter *Gerimus rectum*, that is, we see by a straight line; not in euery position saith *Galen* in the eight chapter of his tenth booke *de rerum partium*, because oblique, side, backward, higher and lower Obiects do not fall in with the ball of the Eye. Nature therefore hath so disposed the Eyes that they may moue & turn themselues on euery side at their pleasure. But *Galen* addeth in the place before quoted, that not only the eyes are moued but also the neck and the head are made moueable for the behoof of the eyes, because there are six positions or places vntowards which the eye ought to mooue; that is to say, vpward downeward, forward backword, on the right hand and on the left. We see by a right line.

It was therefore of necessity that the eyes should haue other helps beside their own motion, for the eyes are not mooued forward and backward, partly because there was no absolute

neces-

neceſsity, and partly becauſe it was impoſsible; it was not neceſſary they ſhould moue forward ſayth *Aquapendens*, becauſe the eye doth not attaine vnto the light but the light vnto the eie, which in a moment enlightneth an infinite ſpace euen vnto the eie, yea inſinuateth it ſelfe thereinto.

But the wiſe Creator hath made amends for the defect of this motion of the eyes by the help of the motion of the head, which out of hād conuerteth it ſelfe to ſee thoſe things which the eie could not by his proper motions perceiue. Moreouer, that wee might ſee whatſoeuer is behind our backe (which could not be done onely by the circumuolutions of the head) Nature hath ſo prouided that the thighes can carry the body round. In like manner the motion of the eye vpward is aſsiſted by the backeward motion of the head and of the whols ſpine, which they haue experience of that ſtriue to take view of the pinnacle of a high Steeple: ſo alſo the motion of the eye downeward is furthered by that motion of the head and of the necke which is forward.

As alſo the motion of the thighes.

Seeing therefore it was neceſſary that the eyes ſhould bee moued with voluntary motion; and all voluntary motion is made by muſcles, therefore our wiſe Creator hath giuen vnto them diuers muſcles whereby their motions are very ſudden and expedite. Hence it is that *Ariſtotle* in the 8. Probleme of the 7. Section calleth the Eye *The moſt noble part of the body*: yet ſayth he, the left eie is more nimble then the right. Now whereas the motions of a mans eye are ſixe according to *Galen* in the third Chapter of his firſt Booke *de motu muſculorum*, it followeth neceſſarily that the eie muſt haue ſixe muſcles; but *Galen*, *Veſalius* and the reſt of the Anatomiſts as *Columbus* ſayth, being accuſtomed only to deſcribe the eies of beaſtes haue added a ſeauenth muſcle, and thoſe ſixe alſo which they haue deſcribed they haue miſplaced. But we are to deſcribe the muſcles of the eye of a man, that ſeauenth which belongeth to beaſtes is deuided into two, into three, and ſometimes into foure.

Why their muſcles are many.

In men therefore as we haue ſaid there are ſixe muſcles according vnto the ſixe motions of a mans eie; foure of which motions are *Right*, that is to ſay vpward, downeward, to the right hand and to the left; the two motions remayning are oblique, to which belong two oblique muſcles whoſe vſe is to rowle the eie about. Notwithſtanding one of theſe is exactly *oblique*, the other partly *right* partly *oblique*. All theſe muſcles are ſeated on the backeſide of the Eye within the cauity of the Scull, whether they accompany the opticke nerue and ſo remayning in their poſition, the eie and they together doe make a Pyramidal or turbinated figure. [Table 1. figu. 6. 7.] Among theſe muſcles the thicker and more corpolent are the *Right* which haue all the ſame ſtructure, originall and inſertion, and do paſſe ſtraight al along the length of the eie; the oblique muſcles are leſſe fleſhy yet very like one another.

Why ſixe,

How many motions the eie hath.

The figure of the eie.

All theſe muſcles of the eie are ſmall that they might be ſooner mooued; but that which helpeth moſt the volubility of their motion is the round figure, which is the nimbleſt of all others, as we may perceiue by the roundnes of the heauens.

Why the muſcles are ſmall.

The eie therefore being round as are alſo the muſcles thereof, is euen in a moment conueyed ouer the whole heauen, and the head it ſelfe is therefore mooued very ſuddanly and ſwiftly, becauſe it toucheth vpon the bone whereon it reſteth with a narrow point.

Why round,

The foure *Right* muſcles meeting and touching one another toward the roote of the nerue optick, doe ariſe with a ſharp beginning frō the lower part of the bony orbe which is made by the wedge bone, hard by the paſſage through which the nerue of ſight or the opticke nerue doth yſſue. I know well that *Veſalius* is of opinion that they ariſe out of diuers parts and into diuers parts are inſerted. Againe for their matter, he conceiueth they ariſe from a commixture of the *Dura mater* which compaſſeth the opticke nerue and a nerue of the ſecond coniugation. *Platerus* thinkes that they ariſe from the membrane which compaſſeth the orbe of the eye, and that membrane which inueſteth the opticke nerue. *Aquapendens* imagineth they proceed from the *Pericranium* or Scull-skinne. *Laurentius* diſputeth about their originall on this manner; They erre, ſaith he, which thinke the muſcles of the eie doe ariſe from the inner thicke membrane which compaſſeth the opticke nerue, for this is altogether againſt ſence; they could not ſayth hee ariſe from a membrane nor they ought not. They ought not, becauſe a membrane of an exquiſite ſence compaſſeth the nerue, which nerue the muſcles in their motions would compreſſe, and ſo the ſight would be offended. They could not becauſe they are not eſtabliſhed vppon a firme foundation. It remayneth therefore, ſaith *Laurentius*, that they muſt ariſe from the inmoſt depth of the orbe

The right muſcles.

Diuers opinions about their original

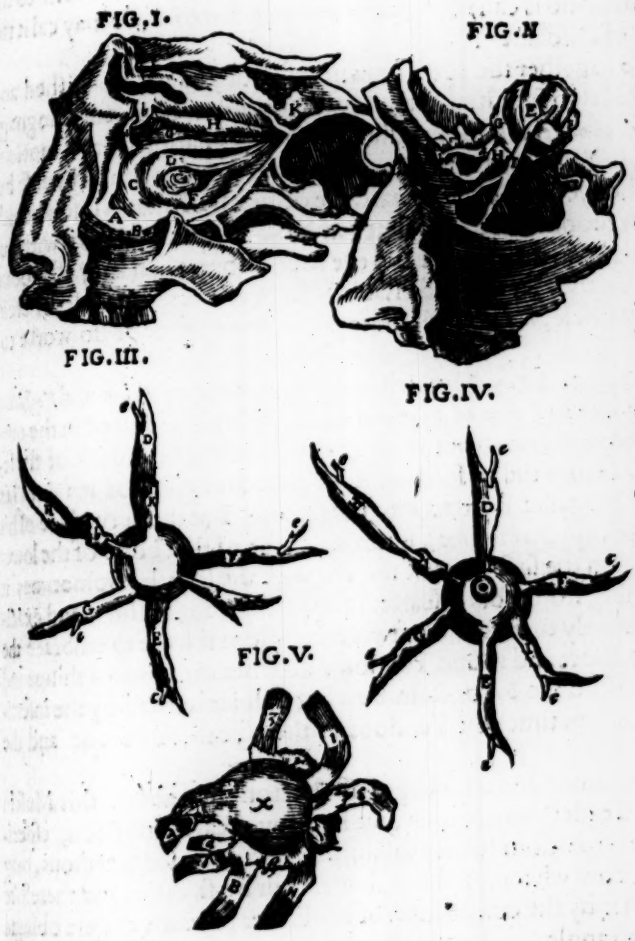
Table 2. Figure 1. ſheweth many muſcles of the Eye in their owne ſeate.

Figure 2. ſheweth the Eye rowled vpward whereby their muſcles may be perceiued.

Figure 3. and 4. ſheweth the muſcles of the Eye, ſeparated before and behind with their nerues.

Figure 5. Is the Eye of an Oxe, with his muſcles ſeuered as Veſalius doth ſhew it.

TABVLA. II.



A, The eie-lid. B, The *Tarſus* or griſtle where the haires grow.

C, the muſcle lifting vp the eye lid.

D, 1, 3, 4, the right vpper muſcle of the eie in 3, and 4, with the nerue.

E, 2, 3, 4, the right lower muſcle of the eye, in 3 and 4 with the nerue,

F, 1, 2, 3, 4, the right externall muſcle of the eye.

G 1, 2, 3, 4, the right internall muſcle of the eye.

H, 1, 2, 3, 4, the oblique ſuperior muſcle or the pulley, whoſe tendon is marked with *a* and the pulley with *b*.

I 2, 3, 4, The oblique inferior muſcle of the eye.

K 1, 3, the optick nerue.

a 1, 2, The tendon of the oblique ſuperior muſcle.

b 1, 2, the ſayd pulley, a ſmall griſtle where through the tendon doth paſſe, & in the 3 and 4 pulled from the bone.

cccccc 3, 4, the mouing nerues of the eies.

αβ, 5, the ſecond muſcle of the eye-lid lying in the cauity of the eye, whoſe broad tendon *β* is inſerted into the eie-lid.

γ 5, the haires of the eie-browes.

δ ε 5, two right muſcles leading the eie vpward and downward.

ζη 5, Two right muſcles mooving vnto the right and left ſide.

B 1, 5, two oblique muſcles lightly turning the eye.

κ 5, the ſeauenth muſcle which may bee deuided into more.

λ 5, The Optick nerue.

orbe or cauity. But we reſt vpon *Bauhines* opinion for their originall.

Their whole bodies throughout their whole courſe are fleſhy, and their bellies beare out round as they come forward. But they determine a little aboue the middle of the eye into a broad thinne and membranous tendon wherewith they compaſſe the whole eye before, and grow very ſtrongly to the horny Tunicle neare vnto the *Iris* or Raine-bow in the greater circle: and theſe tendons ioyned together doe make that nameles coate of *Columbus* and the white of the eie. Their inſertion,

For we conceiue that this whiteneſſe is cauſed rather by the tendons of theſe muſcles then that it properly belongeth to the coate which we call *Albuginea*. And ſo much ſhal be ſufficient to haue ſpoken in generall of the muſcles of the Eie. Now we come to a more particular diſcription of them one by one. Whence the whitenes of the eie proceedeth.

The firſt [Table 2. figure 1, 3, 4. *b* fig. 5. *δ*] which is the third according to *Veſſalius*, and *Galen* alſo in the 8. Chapter of his 10. Booke *de vſu partium*, is ſeated aboue; fleſhy it is & round, thicker alſo then the reſt, greater and ſtronger then the ſecond, becauſe it lifteth the eie vpward toward the brow. For there is greater ſtrength required to lift a thing vp, then to pull it downe. The names of this muſcle commonly giuen by Authours are, *Attollens* and *Superbus*, the *Lifter* and the *Proud* muſcle. A more particular deſcription of the ſeueral muſcles.

The

The ſecond which according to *Galen* and *Veſalius* is the fourth [Table 2. figure 2,3,4. E. figure 5.[d]] is oppoſite vnto the former and placed in the Lower part; it draweth the eye downeward to the Cheeks, and therfore needed not be ſo great as the former, becauſe the eye declineth eaſily with his owne waight. It is called *Deprimens* and *Humilis*; the *Depreſſor* and *Humble* Muſcle.

The third [Ta.2.fig. 1,2,3,4[c]. fig.5,[c]] according to *Galen* and *Veſalius* the firſt, is ſeated in the great angle and leadeth the eye inward toward the noſe, and is called *Adducens* and *Bibitorius* we may call it the Gleeing Muſcle.

The fourth [Tab.2.fig.1,2,3,4[e]. fig. 5,[n]] which according to *Galen* and *Veſalius* is the ſecond, is oppoſite to the third, ſeated on the outſide of the eye which it draweth to the leſſer angle ot to the temples, and is called *Abducens* and *Indignatorius*, we may cal it the Scu-muſcle or the Muſcle of Diſdaine.

The it Vſe. If all theſe foure worke together the eye is drawne inwarde, fixed, eſtabliſhed and conteined, which kind of motion Phyſitians call *Motus Tonicus*, wee in our Language cal it a Set or wiſt-looke. *Archangelus* is more diſtinct in the aſsignation of the motions of theſe Muſcles, for (ſaith he) whē as at diuers times they are moued with any pauſe betwixt their motion, then the eye is mooued toward the originall of that Muſcle which worketh. But when they are mooued at diuers times without any pauſe, that is, with immediate ſucceſsiue motions, then they mooue the eye round: but when they all mooue in the ſame moment then do they ſet fixe and eſtabliſh the Eye immooueable, wherein they are holpen by the fift Muſcle, whether all foure doe mooue a part or do worke together.

The fifth [tab. 2. fig.2,3.4.[f] fig. 5.[a]] which is alſo according to *Galen* and *Veſalius* the fifth, but the ſixth according to *Fallopius*, *Platerus*, and *Laurentius*; is ſeated in the outſide at the depth of the cauity and ariſeth betweene the eye and the Tendons of the ſecond and fourth Muſcles; which is the reaſon why ſome haue thought that it taketh his originall from the Eie and is againe inſerted into the ſame. But the very place of his originall is at that cleft which appeareth like a ſuture or ſeame of that bone of the lower part of the Orbe which ioyneth the firſt bone of the iaw with the fourth. Sometimes it ariſeth with a fleſhy beginning from a bony ſcarfe. It is ſlender, round, ſhort and exactly oblique, and paſſeth obliquely toward the outwarde angle as it were to embrace the eie, and is implanted with a ſhort and round Tendon, degenerating into a thinne and Neruous termination neere vnto the *Iris* or Rain-bow but obliquely, hard by the inſertion of the ſixt Muſcle, ſo that ſometimes the Tendons of them both, ſerue one and the ſame.

To recite heere the contentions and challenges of Anatomiſtes about this Muſcle would rather entangle our Readers minde then giue him any great ſatisfaction, eſpecially ſeeing thoſe learned men to whom ſo nice diſquiſitions will not ſeem tedious, may repaire to thoſe fountaines from whence we haue drawne our by-ſtreame, and therefore we paſſe on to the vſe which is by the contraction of his Fibres to rowle the eie obliquely downward to the outward angle.

His original. The ſixt [Tab.2.fig. 1,2,3,4.[m] fig.5.[i]] which is the ſixt alſo according to *Galen* & *Veſalius*, but the fift according to *Falopius*, *Platerus* and *Laurentius*, is ſeated on the inſide and the vpper part, yet vnder the right Muſcles, and is partly right and partly oblique. It ariſeth from the ſame place with that Muſcle which draweth the eye directly vnto the inner angle at the ſide of the Opticke Nerues paſſage, which is in the verie depth of the Orbe.

His end or Tendon. It endeth as well in man as in bruite beaſtes into a round, ſmall and long Tendone, [Tab.2.fig.1,2.[a]] almoſt at the vtmoſt brimme or edge of the inward angle. This Tendon is reflected through a ſmall griſtle hollowed like a Caue and ſcituated in the greater angle, which *Fallopius* firſt of all men called *Trochlea* or the Pully, & thence proceeding obliquely to the right angle [Ta.2,fig.2,[b] but in the thirde and fourth figure it is ſliuen from the bone] toward the vpper part of the eye, it is inſerted betweene the firſt and the fifth Muſcles with an oblique line, all which time the foreſaid Tendon is compaſſed about with a certaine Ligament as it were with a ſheath.

His progreſſe. *Falopius* his *Trochlea* or pully.

His inſertion.

This Muſcle being drawne inward toward his originall with his Tendon he turneth the eye in a circular motion to the inward Angle. Theſe two turning Muſcles the one vpwarde the other lower are called *Circulares & Amatorij*, the rowling or glauncing

Muſ-

Muſcles, ſome alſo call the ſixt *Muſculum Trochleæ*, or the Muſcle of the pully.

The ſeauenth Muſcle which is for the moſt part found in brute beaſtes, excepting the Ape and Fiſhes, is placed [Tab. 2. fig. 5. x] vnder the former ſixe, and hath of it ſelfe that figure which the former ſixe do together make. It is ſhort and compaſſeth round about the Opticke nerue, [Tab. 2. fig. 5. A.] yet is their ſome fat betweene them. Proceeding forward it is dilated and embraceth the whole globe of the eye euen to the roote. It maketh alſo a circle like as the foure firſt did at the *Rainbow* make a circle with their chords or Tendons: at his inſertion, which is into the hard tunickle of the eye, it becometh fleſhy and may be diuided into three or foure; ſo as *Galen* in the fourth chapter of his fift booke *de diſſectione Muſculorum* maketh a doubt whether it be one Muſcle, or double or treble. The 7. belonging to a beaſt.

The vſe of this Muſcle is to tie vppe and ſtrengthen the eyes of brute beaſts hanging alwayes downeward, that they ſhould not fall with their own weight. It alſo incompaſſeth the nerue Opticke therby making his paſſage, not only ſtraight but alſo warranteth it frō diſtention & frō leaning againſt the bone in violent concuſsions or ſuddain motions. *Galen* addeth in the booke before named, that in that motion which we called *Tonicall* or the fixing of the eye, it eſtabliſheth the ſame when we would accurately diſcerne any ſmall body; for he ſuppoſed this Muſcle alſo to be in men.

But Nature or the God of Nature rather, did not ſee it needfull for mankinde, becauſe his countenance is erected vp to heauen, and if at any time hee bee conſtrained to looke downward, he hath all the foure right Muſcles with their ioynt ſtrength to ſuſtaine his eye, becauſe their Fibres grow to the Membrane which compaſſeth the Orbe. Why a man hath not the 7. Muſcle.

Falopius addeth an eight Muſcle found in Oxen which draweth that griſtly Membrane which *Ariſtotle* in the twelft chapter of his ſecond booke *de hiſtoria Animalum* calleth the *skin of the angle*, with which Membrane brute beaſts do blinke when they feare leſt any thing ſhould fall into their eyes: vnleſſe any man ſhall thinke this is a part of that Muſcle which draweth the eye to the outward angle.

To finde out theſe Muſcles of the eye, when the Braine is taken away you muſt cut the Orbe at each corner euen to the Opticke nerue with a ſaw, hauing a great care leſt the Trochlea or pully which is in the inner angle be offended. Howto make diſſection beſt to find out theſe Muſcles

Next you muſt ſeparate the *Pericranium* from the bone, and bend the vpper part of the Orbe backeward, then take away the fat and ſo ſhall you perceiue the Muſcles of the eye lids, and of the eyes themſelues together with their veſſels; and if you would obſerue the proper and peculiar motion of euery Muſcle, you muſt preſerue them in their proper poſitions and tie to euery one of them a thred not farre from the Tendons, then draw the thred and the draught thereof will deſcribe vnto you the vſe of the Muſcle to which it is tied.

You may alſo take the eye whole out of his Orbe together with the Trochlea, which is in the inner angle and ſo demonſtrate what you pleaſe. And thus much ſhall bee ſufficient to haue ſpoken of the Muſcles of the eyes. Now we proceede vnto their veſſels.

CHAP. V. *Of the veſſels of the Eyes.*

FOr the ſame reaſon for which we intreated preciſely of the Muſcles of the eye in their Hiſtorie, we will alſo handle their veſſels more diſtrictly in this place, and paſſe them ouer more lightly in the booke of Veſſels. The veſſels are here fully handled.

The veſſels therefore which are ſent vnto the eye are veines and Arteries, to which are added Nerues, as being cōmon Organs no leſſe then the other. Veines.

The Veines which are ſent vnto the eye proceed out of the iugular Veines & leade blood for their nouriſhment.

The Arteries ariſe from the *Carotides* or ſleepy Arteries, and are diſperſed through the muſcles to moderate the inward heate, and to ſuſtaine their life; through which Muſcles as alſo through the fat they are accompanyed with Nerues, and diſtributed through their Membranes, which is ſhewed in the third Table the ſecond and third figures at h. Arteries.

The Nerues are of two ſorts, *Optici* and *Motorij*; that is, *ſeeing* and *mouing*; they proceed out of the marrow of the braine yet remaining within the ſcull and making the ſpinall marrow. Nerues.

The Opticke Nerue [tab. 2. fig. 1 and 3. x. fig. 5. A. tab. 3. fig. 2. 4. 8. a.] which is called *Viſorius* or the Nerue of ſight, is on each ſide one, and theſe are amongſt all the nerues of ſenſe the largeſt, the thickeſt, the ſofteſt, and *Galen* alſo ſaith the longeſt in the third chapter Opticke.

ter of the ſixteenth book *de vſu partium*. They are of a rare texture cõpaſſed with both the Meninges. [tab. 3. fig. 2. a b c.] They are the greateſt and thickeſt of all the Synewes, that ſo aboundant faculty might be tranſported to the eye, that it might ſooner haue ſenſe of the light, and be manifold wayes affected.

Why the greatest and thickest.

They are very ſoft ſaith *Galen* in the fifth chapter of his ſeuenth book *de placitis*, that they might be ſooner affected becauſe they are nerues of ſenſe and of a ſenſe ſo very neceſſary, for all ſenſe is perfected by receiuing and ſuffering. They are ſofter then any other, becauſe they are affected by the light alone, which they receiue alſo very much broken. They are the longeſt of all the reſt, becauſe the way is long from their originall to the Orbe of the eye. Their texture is rare and thin, and therefore *Herophilus* beleeued that they were perforated: and *Galen* thereupon called the πορους and *meatus viſorios*. For in the third chapter of his ſixeteenth booke *de vſu partium*, hee noteth out of *Herophilus*, that they are in their inſide perforated all along their paſſage, and that perforation was the reaſon why they were made ſo large.

Why ſofter.

Galen out of *Herophilus*.

By theſe *Galen* thinketh not onely that the faculty of ſenſe is tranſported, but alſo the Animall ſpirits in which the faculty is eſtabliſhed, that ſo their ſenſe might be more aboundant and ſtrong: whereas through other Nerues he conceiueth that the vertue or faculty onely is carryed as we may perceiue in the 12. chapter of his tenth booke *de vſu partium*, and in the fifth chapter of his ſeuenth booke *de placitis*. Theſe Opticke nerues in their end and in their originall are diſtinct, but at the middle of their progreſſe aboue the ſaddle or ſeat of the wedge bone, before they ſal out of the ſcul becoming a litle broader, the right is vnited with the left [tab. 21. lib. 7. fig. 1. oo.] ſo that they make the forme of the Greeke χ, not by cleauing the one to the other, or by intercuſſation, or that one rideth ouer the other, but by perfect and abſolute vnion and confuſion of their marrowes they are ſo ioyned that one cannot be ſeparated from the other, [tab. 21. lib. 7. fig. 1. ss] for it is a very rare thing in Anatomie to find them ſeparated.

Where they are diſtinct. Where vnited.

The vſe of this coniunction is, partly that the *Papilla* or ſight of the eye might look vpon the ſame plaine leaſt otherwiſe the viſible obiects ſhould appeare double becauſe the eyes are double: partly that the *Idea* or formes of viſible things might be vnited and ſo the faculty of ſight be common to both ſides, becauſe the viſible ſpirit may paſſe from one eye to another in a moment for the more certainty of the ſight: And this is prooued if we preſſe or inforce one eye vpward or downward, for then all things appeare double: wherefore as it was conuenient that the eyes ſhould be pararels; ſo alſo the nerues, which becauſe of the motion of the eyes might decline from the right line, eſpecially ſeeing the muſcles do compaſſe them and cleaue vnto them: for when one muſcle onely whether it be the vpper or the lower is moued, the eye alſo is rowled to one ſide. And therefore Nature hath worthily ioyned the Opticke nerues together, that euen in ſuch motions the faculty might be wholly conuaied to either ſide. And this appeareth to be true becauſe if you put your hand betwixt your eyes along the length of your Noſe, ſo that you cannot ſee the obiect you intend with both eyes, you ſhall perceiue that you ſee more obſcurely on either ſide, then if you lookt vpon the obiect with one eye ſhut vp, for then the faculty which was before diſperſed vnto both, is vnited into one. Adde alſo this third profit of the coniunction, that the ſoft nerues hauing a long way to go, might thus be made ſtrong and eſtabliſhed, becauſe Nature could not ſuſtaine them with any ties or knots of Membranes. After their coniunction they are inſtantly diſioyned, and each nerue iſſueth through the proper hole which is framed in the depth of Orbe out of the ſcull [Tab. 21. lib. 7. fig. 1. aboue ss.] and ſo the right attaineth to the right, and the left vnto the left eye, and there are implanted.

The vſes of their coniunction.

In a man they are inſerted on the backeſide into the center of horny coate [ſee the third table fig. 2. 3. 4. 8.] becauſe onely man can look directly forward. In brute beaſts as in oxen and horſes, whoſe eyes are much farther a ſunder, they attain by a line notably oblique vnto the compaſſe of the eye and do not determine in the Center. Hence it is that the eyes of brute beaſts doe ſee the earth on either ſides to direct their gate and to finde out their nouriſhment. Theſe Opticke nerus when they are come vnto the eies are dilated ſaith *Galen* in the 1. chap. of his 10. book *de vſu partium* and like a membrane each of them incõpaſſe the glaſsie humor *Galen* alſo addeth in the ſame place that they are inſerted into the Criſtalline humour.

The vſe of the optick nerues

The vſe of theſe Opticke nerues is to leade the viſible faculty from the braine which in the

the eies is gathered vnto the visible formes, where the Nerue is dilated into the Membrans of the eie. For if this Nerue be obstructed as it is in that disease which the Arabians call *Gutta serena* the cleare drop, the action of seeing is altogether taken away or intercepted. And so much concerning the Optick Nerues. *Gutta serena.*

The Nerues of Motion are on either side one, which sendeth a small surcle to eache Muscle by which it is mooued [Tab.2.fig.3.4. sheweth this] (as he may perceiue who diligently shall separate the beginning of the Muscles from the Nerue) which also is spred abroad into the Membranes. These mooving Muscles in their originall are continuall, that is, the right is ioyned with the left, whence it commeth to passe that when one eye is mooued, the other also followeth the same motion: for they proceede ioyntly out of one point as it were in the fore-part of the spinall Marrow, so that the same obiect and the same light, after the same manner and at the same time insinuateth it selfe into either eye, that the sense and discerning might be one and the same; and this maketh much to the perfection of the sense that one and the same thing might not appear double, which doubtlesse would happen if one eye might be mooued vpward and the other downward at the same time. That this is true you may easily learne if with your finger you either depresse or lift vp one of your eyes, for then all obiects will appeare double, one higher another lower. But if you mooue your eye toward the side, because the *pupilla* or *Sighte* are in the same line, the obiects will not seeme double. Wherefore *Galen* in the thirteenth chapter of his tenth booke *de vsu partium* writeth, that the Diameters of the visible Cones must be placed in one and the same plaine, least that which is one do appeare double. The Nerues of motion. Where they are continuall Demonstrations hereof.

Hence it is, that in the palsye and convulsion of the Muscles of the eye the patient often seeth double Obiects, because the eyes do depart from the same plaine. So also when the Opticke Nerues are either conuelled or relaxed the *pupilla* or *Sight* not beeing in the same line, all thinges appeare double, which also for the same cause happeneth oftentimes to men when they are drunke.

From these Instrumentes Veynes, Arteries and Nerues are deriued vnto the eye; aboundance of Spirits Natural, Vitall and Animall, which are properly called visible spirits: wherfore acording to the plenty of the Spirits conteyned in the eyes, their magnitude as also their splendor or brightnes is greater or lesse. And hence it is that whē men are nere their death their eyes becom litle, languid & obscure, as also those that do too much follow venerial combats haue their eyes smal and extenuated, so also wee see that in liuing men the eyes are full and turgid, but when they are deade they become lesse as also laxe and rugous, for the presence and absence of the spirits maketh a difference betwixt a liuing and a dead eie. The spirits of the Eies.

Againe, according to the diuers disposition of the spirites and of the eyes from them, we are able by our sight to distinguish and iudge oftentimes of the affections of the mind, which is a cleare argument and euen liable to our sense, that the body of a man is ful of spirits, which thing *Galen* also in the tenth booke *de vsu partium* prooueth by an elegant and demonstratiue argument. For (saith he) if vpon the closing of one eye you do attentiuelie marke the *pupilla* or sight of the other, you shall perceyue it in a verie moment to be dilated, because a greater quantity of spirits do fall into the Grapie coate which we call *Vuea*, through that coate which is called *Reticularis* or the Nette, where they dilate the hole of the *Vuea*, which hole is properly called *Pupilla* or the sight and Apple of the eye. Finallie, that the eyes are full of spirites is hence conuinced, because they are sometimes obscure, dull and languid or weake, sometimes bright or shining, quicke and apprehensiue. But least these spirites which are of an admirable fineneſſe and subtiltye might exhale or euaporate they are kept in and retained by a thick, thight and strong Membrane which is called the Horny coate. Diuers argumentes to proue there are spirites in them.

CHAP. VI. *Of the Membranes of the Eyes.*

HAuing declared the Muscles & the vessels of the eies & now remoued them away, the eye it seife round like a bowl appeareth [Ta.2.fig.3 & 4. Ta.1.fi.2 & 3] which may be compared to the world & an egge, both for the figure & construction. To an Egge which consisteth of Membranes, the shel which is an indurated Membrane & a thin Membrane vnder it, & humors, the white & the yolke: So the globe of the eye hath membranes & humors. Membranes that being of a watery nature it might better be conteined in his positiō and the humors by them encompassed, which membranes had need to haue a more solid The eie compared to an Egge.

 substance, be-

substance, beside they are a great furtherance to the sight: Humours onely for the sight:

The Membranes of the eie.

Concerning the number of the Membranes the authors are at great difference. *Hippocrates* in his Booke *De Locis in Homine* acknowledgeth but three, the vppermost thick, the middlemost thinner, and the third thinnest of all which conteineth the humors; but in his booke *De Carn.* he saith they are manie. The later Grecians reckon four, *Siluius* fiue *Vesalius* sixe, *Galen* in the seuenth chapter of his tenth book *De vsu part.* seuen; vnto which *Fuchsius* & *Aquapendens* do consent. We wil diuide them into two kinds, some are common to the whole eie, some are proper to the humors; the common Membranes are the *Cornea* and the *Vuea* the horny and the grapie coates. The proper Membranes are the Cristaline and the glassye. But whereas there are commonly reckoned seauen, *Adnata*, *Cornea*, *Dura*, *Vuea*, *Choroides*, *Aranea*, and *Retina*, whereto some haue added those which are called *Vitrea* and *Innominata*, we wil runne thorough them al after our Anatomical order.

Their number verie diuerse according to authors.

First *Adnata.*

The first is called *Adnata* which is the seauenth according to *Galen* in the second chapter of his tenth booke *De vsu partium*, so called as it were *Nata circa oculum*, bred about the eye. *Galen* cals it ἐπιπεφυκὸς, because it cleaueth on the outside of the other membranes of the eye, whereupon it is also called *Adherens* or the cleauing Membrane. This is the vtmost. *Aquapendens* supposeth that it ariseth from the *Periostium* & tendons or chords of the Muscles. It first offereth it selfe before Dissection together with the transparant part of the horny Membrane lying vpon the white thereof.

The *Periostium* is alwayes next vnto the bone, vnlesse it be wher it produceth the eyelid, for hauing therto attained it maketh an angle & so is doubled, one part of which duplication compasseth the lid of the eye, the other part [Ta.1.fig.6,7,8,V] maketh this *Adnata* or adhering Membrane, which becomming thinner in the fore-part only where the white of the eye appeareth, couereth the same and determineth or endeth in the greater circle of the *Iris* or *Rain-bow*, where it is continued with the hornie Membrane. [Tab.1. fig. 7.8. V. and Tab. 3.fig.1 d]

Whence commeth the white of the eie.

It is said to be white from the colour, although saith *Aquapendens* it be not indeed white but onely appeareth so, because the Tendons of the Muscles lying vnder it do represent a kind of whitenesse. But *Hippocrates in Coacis* calleth it λευκὸν, the white of the eye. It is a smooth Membrane, and by the interposition thereof the eye is fastned to the orb and to the inner bones, and it serueth instead of a Ligament to all the bones about the eye. Hence it is called commonly *Coniunctiua a Coniungendo*, because it ioyneth together all the Membranes of the eye, thereby making it firmer and stronger, or rather because at the *Iris* or *Raynbow* it is ioyned to the rest of the Membranes.

Coniunctiua.

The vse of the *Adnata.*

In like manner it tieth the eie to eie-liddes and to the head, and in a worde it defendeth the eie from the hardnesse of the bones, it ioyneth it with the bones, the liddes, and the rest of the coats, whereby it is so established that in violent motions it doth not fall out of his orbe, but is freely mooued; and besides it couereth the Muscles which mooue the eie and keepeth them in their proper seates but because it hath rather the vse of a Ligament then of a Membrane, we thinke it approacheth nearer to the nature of a Ligament.

The vessels of this coate.

This coate or Membrane or Ligament whither you list to cal it, is sprinkled with manie smal Veines [Tab.1.fig.6.7.8.V] and Arteries, which commonly when the eie is in perfect health do not appeare. Sometimes they grow verie red and being ful of bloode they strut therewith and so become more conspicuous as in the inflammation of the eie. For as *Hippocrates* hath it, sometime this white groweth red or blackish, or is ful of black Veines; this Membrane or coat it is which communicateth to the eie the sense of Touching, because neyther without nor within it hath any sense at al, and therefore the pain which proceedeth from the eye-liddes molesteth the Eye onely by reason of this Membrane.

The 2. Coate *Innominata.*

The second Coate of the Eye is called *Innominata* by some, as if it had bene but newly found out, whereas *Galen* knew it wel enough, and in the second chapter of his Tenth booke *De vsu partium* reckons it for the sixte Membrane. It ariseth from the Neruous Tendons or Chords of the Muscles and determineth neere the Iris vnder the *Adnata* or Coniunctiue Membrane: and these Tendons do encrease the whitenesse of the eye, because they haue a bright *Candor* or whitenesse. But being nothing lesse then the Chords

of

TABVLA. III.

The explication of the first Figure by it selfe.

a. The Cristalline humour.
b. The Glassy humour.
c. The watery humour.
d. The vtmost coate called *Adnata*,
e. the dark part of the horny Tunicle which is not transparant.
f, the Grapy coate called *Vuea*.
g, the Net-like coate called *Retiformis*.
h. the coat of the glassy humor cald *Hyaloi-*
i, the coate of the Cristalline. (*des.*
kk, the hairy processes cald *Processus ciliares*
l, the impression of the Grapy coate where it departeth from the thick coate.
m, the horny coate, a part of the thick coate
nn, the fat betwixt the Muscles,
o, the Optick Nerue,
p, the *Dura Meninx*.
q, the *Pia Mater* or thin Meninx.
rr, The Muscles,

The explication of the other 19. figures togither

a, 2,4,8. The Optick Nerue,
b, 2,4. The thin *Meninx* clothing the nerue
c, 2,3. the thick *meninx* clothing the Nerue.
d 8, the posterior part of the horny Coate.
e 8, the coate called *Retina* gathered together on an heape.
f, 2,3, the Raynbow of the eye.
g, 2, 3, the lesser circle of the eie or the *pupilla*
h, 2,3. Vessels dispersed through the *Dura Meninx*.
i, 3, 6. the Grapy coat, but *i* in the 3. Figure sheweth how the vessels doe ioyne the hard membrane with the Grapie coate.
k, 6. the horny or hard membran turnd ouer
ll, 3,4. Certaine fibres & strings of vessels, wherby the grapy coat is tied to the horny.
mm, 4, 5. the impression of the Grapie coate where it recedeth or departeth from the horny coate.
nn, 4, 5, 6, 7, the *pupilla* or Apple of the eye.
oo, 7, The Ciliar or hairy processes.
p, 7. The beginning of the grapy coat made of a thin membrane dilated, but *p* in the 17. figure sheweth the Ciliar processes sprinckled through the fore-part of the glassy humour.
r 9, the bosom or depression of the glassye humor receiuing the Cristaline. (line
s, 12, 15, the bredth of the coat of the crista-
t, 12. 13, 14, 16, the *posterior* part of the cristaline humor which is spherical or round.
u, 11, 14, 20, the fore-part of the same Cristalline depressed.
x, 10, 20, the amplitude of the glassy humor
y, 10, 16. 19, the amplit. of the watry humor
z, 10, the place where the glassy humour is distinguished from the watry by the interposition of the *Hyaloides* or coate of the glassy humor.
a, 10, 16, the place where the grapie Coate swimmeth in the watrie humour.
ß, 18, The Cauity or depression of the glassy humor which remaineth in the Cristalline is exempted or taken from it.
d, 19. The cauity or depressiō of the watry humor made by the same meanes.

of the muſcles, it cannot bee properly called a membrane but a part of the muſcles, which together with them muſt needs be demonſtrated, notwithſtanding if any man liſt to ſtand vpon it and call it a membrane we will not gainſay him.

The vſe of it, The vſe of it is, that by the interpoſition thereof the muſcles might bee more fitly inſerted into the horny membrane [tab. 2. fig. 5. ſheweth the ſame.

The 3. coate *Cornea*. The third coate of the eie is called *Cornea*, which is the firſt according to *Hippocrates*, and may well be called the thicke and hard coate both in reſpect of his ſubſtance and of his originall, becauſe it is produced from the hard Meninxe or the *Dura mater* which inueſteth the opticke nerue. And here we may take knowledge of the admirable wiſedome of our Creator, who (as *Galen* hath excellently obſerued in the 2. Chapter of his tenth Booke *de vſu partium*) whereas in no other place hee hath ſeparated the Meninges from any Nerue which are produced with them, but hath led them along with the nerue that they might be nouriſhed & couered; only in this place after the nerue is inſerted into the eie, hath ſeparated both the thicke and the thinne from the nerue it ſelfe; yea made them thicker and harder then they were when they encompaſſed the braine. For when this membrane is implanted into the backpart of the eye [Table 3. figure 3. c] it is dilated and maketh an orbicular or round membrane [Table 3. figu. 2 and 3. exhibite it] which compaſſeth the whole eie, although it bee not in euery place alike, neither haue one and the ſame name; for the forepart is tranſlucid but the backepart is not ſo; wherfore ſome immitating the Arabians of this membrane how made two. For becauſe the ſight did ſtand in need of tranſparencie, this membrane, when it hath attayned vnto the middle of the forepart of the eie iuſt againſt the Criſtaline humor, it is ſo condenſed that it degenerateth into a horny ſubſtance, which forepart [Table 3. fig. 1. tm] is called κερατοειδὴς *Cornicularis* that is Horny, becauſe in the middle as farre as the extent of the Rainebowe it is like a thinne and polliſhed horne of a Lanthorn, not only in tranſparencie by which meanes it receiueth the light, but alſo in his ſubſtance, becauſe it may be ſliuen or deuided into diuers flawes. And that was the reaſon why *Fallopius* in his obſeruations could not perſwade himſelfe that it was a part of the hard membrane becauſe, ſaith he, it differeth from the *Dura meninx* of the braine, not onely in ſubſtance but alſo in thicknes and in figure. For by it ſelfe alone it maketh another ſpherical cauity ariſing beyond the ſuperficies of the hard membrane, and both within and without is free from any connexion.

How it is ſpred ouer the eie.

Why it is compared to a horne of a Lanthorne.

Fallopius his opinion.

The forme & diſpoſition thereof. This horny membrane is round, circular, hard, faſt, thin, ſtreatched, tranſparant, bright, polliſhed and ſmooth. Round and circular in a man (for in Oxen it is of an ouall figure) bunching or bearing out in the middle of the eye: not onely that it might bee freer from being offended: but eſpecially that the eie might diſcerne things greater then it ſelfe; that is, that it might receiue the *Ideas* or formes of great obiects and thoſe whole & vnbroken, as alſo that the light which entreth in might be better vnited and contracted, and ſo attaine through the *Pupilla* or Apple vnto the Chryſtaline humour. That this benefit commeth by the roundneſſe and prominence of this membrane may be demonſtrated by a Looking glaſſe, for if we deſire to ſee our faces in a long fragment of a Looking glaſſe we cannot ſee them whole, becauſe the figure is playne, and in a plain figure the perpendicular beames of the light are not vnited: whereas in a round figure they concutre and meete together into a poynt: for *Galen* ſayth in the twelfth Chapter of his 10. Booke *de vſu partium*, that *Viſion* or *Sight* is made by a *Pyramis*, and therefore let the glaſſe bee neuer ſo ſmall, yet if it bee round wee may ſee our whole face therein: hence it appeareth that if this part had any figure ſauing a circular, the images or formes of great obiects could not bee admitted into the eie at all.

Why round & circular.

Why hard. It is hard and in ſome Fiſhes ſayth *Aquapendens* exactly carrieth the hardneſſe and rigidity of a horne it ſelfe. This hardnes ſecureth not only the membrane but alſo the Criſtaline humour from outward iniuries: beſide that, it reſiſteth any light occurrent violence.

Why faſt. Faſt and thight it is, not onely for reſiſtance, but alſo for the better conſeruation of the watery and glaſſie humours that they ſweat not out, and that the thinne ſpirites might not penetrate through it and ſo exhale. VVherefore in a liuing creature becauſe of the aboundance of ſpirites, it is notably ſtreatched and ſhineth very cleare eſpecially in the forepart. But when the creature is dead and the ſpirits extinguiſhed, it falleth preſently and growes looſe and corrugated.

Hence it followeth that ſight cannot be by an emiſsion or ejaculation of ſpirites out of the

the eies, becauſe the tention or ſtreatching of a liuing eie proceedeth from no other cauſe but from the aboundance of ſpirits concluded and contayned within this membrane. And although it be the firſt and next part of the eie which is expoſed to all iniuries of cold, heat and whatſoeuer elſe might fall vppon or bruiſe the eye; yet by the wiſedome of Nature it is defended by the lids, by the haires, by the bones and by the skinne. Moreouer it is not a ſimple or ſingle membrane but made as it were of many ſhels or ſcales, vpon which ſayth *Ruffus* in the fift Chapter of his firſt book, there is a cuticle or curtaine ſpread which is far thinner then the reſt of the ſcales, that if haply one of them ſhould be gnawne aſunder, the reſt might ſuffice to contayne and defend the Chryſtaline humour. *Auicen* maketh it fourfould.

It is very thinne, for, ſayth *Galen* in the third Chapter of his tenth book *de vſu partium*, if it had been thicke it might indeede haue beene a defence vnto the eie, but it would haue caſt a perpetuall darke ſhadow vpon it, and would haue hindered the paſſage of the light; whereas now being thinne it tranſmitteth any light or brightnes freely and without delay ſo that the chryſtaline humour may diſcern the true purtraitures and repreſentations of all viſible obiects; wherefore alſo it is tranſparant, cleare and bright becauſe it ſhould be more fit for the tranſmiſsion of illumination, for ſo we ſee that the thinner a horne is the better doth the light extend it ſelfe through it. Why thin.

It is alſo ſtreatched, for if it had beene corrugated or wrinkled and ſo vnequall, it muſt needes haue loſt his roundnes, ſmoothnes and tranſparancie; and ſo the ſight would haue beene much hindered. An experience whereof wee haue in old men in whome this membrane is ſometimes ſo rugous and looſe, that either they can ſee nothing at al or very confuſedly, for, ſayth *Aquapendens*, when one plight or fold falleth vpon another and the coat thereupon is duplicated, the membrane becomes thicker & the Apple contracteth it ſelfe becauſe it is not diſtended by a ſufficent afluence of ſpirits. Why ſtretched.

It is tranſparant that it might giue way to all viſible formes and repreſentations, and alſo admit the light which beateth vpon it. But we muſt conſider that this tranſparancie or lucidity of the membrane differeth much from the lucidity of the aire, that ſo there might inſue a refraction or breaking of the light. But howe the light paſſeth vnto the eye and how it is refracted, becauſe it belongeth rather to the opticke Art then to Anatomy; him that liſteth to be further ſatisfied therein, we wil ſend vnto the writers of the Opticks, ſuch as are *Vitellius* and *Alharen*. *Aquapendens* alſo the Anatomiſt hath elegantly written of theſe things of the eie: but we proceed. Why tranſparant.

This membrane is polliſhed and ſmooth that in it the formes of thinges might better ſhine and more fitly be receiued, and images repreſented to the chryſtaline humour moſt like to the outward obiectes. For if it had beene rough and full of eminencies and cauities, the light would not haue equally attained vnto it; for where cauities are there doe the repreſentations paſſe through more eaſily and brighter; where there is any eminencie ther doe they paſſe through with more difficulty, and beſide are very obſcure. Moreouer ſuch an aſperity or roughneſſe would haue beene troubleſome to the eie-lid, as wee ſee it happeth when any ſmall ſubſtance falleth betwixt the eye and the lid. But being faſt, hard & thinne, it could not receiue any veines into it, neither yet arteries nor nerues: neither if it could had it beene behoofefull, for they would haue hindred the ſight, & although it might haue defended the chryſtaline humour from outward offences, yet it would haue been offenſiue to the ſight with his hardneſſe: and finally it would haue abated the viſible faculty communicated vnto the eies from aboue, and haue dimmed or dulled their brightnes. For that the eyes are offended with a bright and vehement light, euery man hath ſufficient experience in himſelfe. Beſide, we read in hiſtories that *Zenophons* ſouldiours were almoſt blinded by trauelling through the ſnow. And *Dioniſius* that Tyrant of *Cicilia* aboue his priſon built a very lightſome and bright chamber which he whitened ouer with lime, & when he had a long time detained his priſoners in a darke dungeon, hee ſuddenly brought them into this light and bright place, where they inſtantly became blinde becauſe their eies were not able to beare ſo ſudden a change. Why polliſhed and ſmooth. That much light is an enimy to the ſight. *Dyoniſius* his cruelty.

In like manner thoſe that doe labour of the *ophthalmia* or inflamation of the eye are offended with the light: but duskiſh or greene colours they are able to behold without offence. The greater light extinguiſheth the leſſe.

Hence it is that if in a bright light a man would looke on any thing that is a far off, he will hould his handes or ſome other thing ouer his browes to ſhadow his eies that they

be not dazled. So alſo it hath bene obſerued, that thoſe that haue fixed their eyes vpon the Sunne to behold the Eclipſes of the ſame, haue vtterly loſt their ſight. And this commeth to paſſe, euen as we ſee a torch or candle lighted and ſet in a bright Sun is inſtantly extinguiſhed: In like maner if you light a candle and ſet it by a great flame, the candle will preſently go out, becauſe the leſſe light is ouercome and diſsipated by the greater.

After the ſame manner in the eye, not onely the ſpendor of the Criſtalline humour, but with it alſo the brightneſſe of the glaſsie humour is diſsipated: wherefore the wiſe and prouident Creator, ſaith *Galen* in the third chapter of his tenth booke *de vſu partium*, hath interpoſed the coat called *Choroides*, which in many parts is black and duskiſh, and in oxen green; which coate nouriſheth the horny coate that is next vnto it where they touch one another, and hindereth it alſo from falling vpon the Criſtalline humour, although that inconuenience is in part preuented by the roundneſſe and prominence of the ſaide horny coate.

The wiſedom of our Creator acknowledged by *Galen*.

Moreouer, the blacke colour of the *Choroides* in men, and the green colour in Oxen, is a medicinable curtaine or ſhadow for the ill affected eye; and this is the reaſon that euery man by a naturall inſtinct, when he is offended with the brightneſſe of the light, will ſuddenly cloſe his eye-lids, making haſte thereby vnto the remedy which Nature hath prepared, euen within the eye. And this may be further exemplified by the cuſtome of Painters, who when they paint vpon white tables would ſoone haue their eyes offended if they did not prepare againſt it, wherefore they place at their elbowes greene and duskiſh colours, vpon which euer and anon they turne their ſight, whereby their eyes are recreated and refreſhed.

The backe-part of the horny coate.

The poſteror or backeward part of this coate which couereth the back part of the eye and the forepart alſo vnto the circle, [Tab. 1. fig. 7. 8. f] is hard, thicke, darke, or obſcure; differing as much from the colour or cleareneſſe of the horny membrane, as the white of an Egge when it is boyled differeth from the ſame white when it is raw. It is hard and thicke by reaſon of his originall, although it neither imitate the exterior coate of the nerue in thinneſſe, nor the *dura meninx* or thicke membrane of the braine from which that ariſeth in thickeneſſe; as being fourefold thicker then it, for when it formeth the coate of the eye it is thickened and hardned, for it was requiſite it ſhould be very hard and very thicke for more ſtrength, becauſe it maketh the whole globe and cauity of the eye wherein the humours are contained; for this membrane it is which faſhioneth the figure of the eye into a globous roundneſſe, and in that figure conſerueth it: it is alſo made whole, for this coate aboue compaſſeth the whole eye ſo that nothing can iſſue therout.

Why it is ſo thicke.

Add hereto that it receiueth the inſertions of all the muſcles & ſuſtaineth their weight, as alſo the weight of the fat and is a Baſis or foundation of the veines and arteries [Tab. 3. fig. 3. h h.] which neare the nerue behinde the glaſsie humour attaine vnto this membrane and afterward run forward till they be diſtributed through the coate called *Choroides*. By the mediation of theſe veſſels, as alſo by ſmalties, as it were by ligaments this membrane cleaueth ſo faſt to the *Choroides*, that they hang one vpon another. [Tab. 3. fig. 3. h i.] The profit of which connexion is, leſt this coate alone ſhould be moued when the other parts of the eye are at reſt, as we ſee a cloth wrapped about a ſmooth bowle will eaſily ſlippe, though the bowle be not moued.

Why it is thicke and darke.

This membrane is alſo thicke and darke or obſcure, that the *ſpecies* or formes of things which are receiued might ſhine more brightly, as we ſee in a looking glaſſe if it be leaded on the backe ſide we my eaſily ſee our faces therein, but not ſo if the lead be remoued. This part is white, and neither in nature nor in colour like vnto the forepart, and

Fuſchius, *Aquapendens*.

therefore ſome of the late writers as *Fuchſius* and *Aquapendens* haue diſtinguiſhed it from the forpart, and ſay, that the limits and edges therof are continuated with the horny membrane. It is ſcituated vnder the Coniunctiue and Tendons of the muſcles, and is generated out of the *dura meninx* which compaſſeth the Optick nerue, for with it it is continuall, as may be perceiued if you ſeparate the coate of the nerue with a ſharpe knife through his length whileſt you come vnto this membrane. It is called by ſome σκληρότης & σκληρτικὴ

Ruffus.

the *hard* membrane, *Ruffus* calleth it *candida* or the white membrane, although commonly that name be giuen to the *Adnata* or Coniunctiue coate.

The vſe of this third membrane.

By the heple of this membrane is the eye eſtabliſhed, as alſo the next membrane vnto it defended, which is ſufficient indeed to defend that which is vnder it, but not to defend it ſelfe: this alſo is it which containeth the humors according to their due diſpoſition;

ſition; and whereby the Criſtalline humour it ſelfe is preſerued from the cold and heate of the Ambient aire.

CHAP. VII. *Of the Grapie Membrane, the Apple, Rainebow and the Ciliar Ligament.*

THe fourth coate or Membrane of the eye is called by the Greekes βραγειδὴς and ῥωξ; in Latin *Vuea* or the Grapie Membrane, becauſe the colour of it is like the peele of a Grape ſtone or kernell, or it is like the kernell it ſelfe which is on the outſide ſmooth, but within ſharpe and rough; in like manner this Membrane on the outſide which is next the horny Membrane is ſmoth but on the inſide which is next the Criſtalline it is rough or rather vnequal becauſe of the ſcurles of veins and arteries which reach out of the hornie Membrane into it. [Tab. 3. fig. 3 and 4.ll.] Again it reſembleth the Grape kernell in the colour which is blacke, or rather becauſe it containeth a whitiſh humour ſuch as iſſueth from the grape when the ſtalke is pulled off.

The 4. coate of the eye.

The reaſon of the name.

His ſituatiõ.

This Membrane is ſcituated betwixt the *Cornea* and *Retina* vppon which it lieth onely on the backeſide, but forward it is betwixt the *Cornea* and *Aranea* and containeth the waterie humour of the eye. [Tab. 3. fig. 1.c.] It is tyed backeward to the Opticke nerue, and the coate called *Retina*: to the hornie membrane it adhereth by certaine ſurcles of veines and arteries [Tab. 3. fig. 3.] and to the rainbow by Fibrous ties which are not very ſtrong. Before it is euery way free and looſe, that it might be contracted and dilated.

His figure.

The figure of it is not exactly Globous as the former, becauſe it doth not compaſſe the whole eye, but in the forepart [Tab. 3. fig. 4.mn. fig. 7. atn.] it is a litle preſſed inward, where alſo it is perforated with a round hole.

His originall.

The originall of this coate *Galen* ſaith in the ſecond chapter of his tenth booke *de vſu partium* is frõ the *Pia mater*; [Tab. 3. fig. 1.f. fig. 4. and 5.] for when the *Pia mater* or thin Membrane hath inueſted the Opticke nerue, [Tab. 3. fig. 2. b.] it is preſently dilated vnder the *Cornea* to make this Membrane: wherefore it creepeth forward and compaſſeth the whole eye, excepting the forepart where at the greater circle or rainebow of the eye, it is continued with the *Cornea*, & being reflected backeward is duplicated and in the mid perforated, which perforation is called *Foramen vuea*. the hole of the grapy membrane and by a proper name *Pupilla* which we may interpret the Apple of the eie. Notwithſtanding it is farre thicker then the *Pia mater*, eſpecially in the forepart where it is double as thicke as it is behind. Againe, it differeth from the *Pia mater* in colour, for the coate of the Nerue which it receiueth from the *Pia mater* is white, but this is blacke on both ſides.

Why it is called *Chroides*.

Moreouer, becauſe it proceedeth from the *Pia mater* or thin membrane, it is called alſo χοροειδὴς eſpecially, becauſe through it there are many veſſels diſſeminated, & becauſe like the Chorion of the wombe it gathereth thoſe many veſſels and tieth them together; and this in oxen is eaſie to be diſcerned, for in them the veſſels do run through the length of the eye in a conuenient diſtance one from another, from which veſſels certaine threddy filaments or ſmall ſtrings do as it were weaue together this membrane like as it is in the *Pia mater* of the braine. From this membrane alſo the foreſaid ſtrings and threedy veſſels are produced into that coate which wee call *Retina* as may eaſily bee perceiued when this Grapy membrane is ſeparated therefrom.

This Grapy coate therefore is full of veines, ſoft, black, and perforated.

His veſſels.

Why it is ſoft

Full of Veines, that it might nouriſh the horny membrane: ſoft that it might not hurt the Cryſtaline humor, and beſide might readily moue when the *Pupilla* or Apple moueth, which it would not ſo readily haue done if it had beene rigid or ſtiffe.

Why blacke.

It is blacke or rather duskiſh, the better to gather the brightnes of the *Idea* together, and to tranſmit it through the perforation.

Why perforated.

Finally, it is perforated iuſt againſt the Cryſtaline humour, that ſo the Images of viſible things paſsing through the horny membrane and wateriſh humour might at length ariue at the chriſtaline. And although it be moyſt and ſoft and neare neighbour to the chryſtaline, yet is it not offenſiue thereto; albeit on the outſide it be ſomething thicke or rather faſt wrought: for as it was fit that this membrane ſhould not offend the chryſtaline humor, ſo likewiſe was it as fit that it ſelfe ſhould not be offended by the horny membrane; betwixt the tranſparant part whereof and the chryſtaline humour it is ſeated, and yet it toucheth neither of them.

Further

Furthermore, that the chryſtaline humour might not bee offended or touched by the horny coate inſinuating it ſelfe through this hole or perforation, by which the externall brightnes attayneth vnto, and is mingled with the internall; Nature hath ſet that part of the horny membrane outward, and beſide hath diſpoſed about the Chryſtaline a thin and cleare humor like the white of an egge; and laſtly hath filled the whole perforation with an ayery and bright ſpirit. And that this place hath ſuch a thinne moyſture and is ful of ſpirits is hence manifeſt, becauſe in liuing creatures the eye is ſtreatched & fulfilled on euery ſide, no part of the horny membrane remayning looſe or corrugated.

What is contained betwixt the grapy membrane and the chriſtaline humor.

But if you looke into the eye of a dead man before you come to diſſect it, you ſhal find it rugous, and when you haue cut the horny membrane preſently a thinne humour wil offer it ſelfe (which alſo in compunctions of the eye doth vſually yſſue from the wound) and ſo the whole eye will become rugous, contracted and looſe. Againe, if you diſtend and ſtreatch the coates when they are ſeparated from the chryſtaline humour, it will appeare that there is a great diſtance betwixt them emptie, which while the creature was aliue was vndoubtedly filled vp with ſpirits or humour or both

The like alſo may be demonſtrated in a liuing eye, for if one eye be ſhut the *Pupilla* or Apple of the other will bee dilated, inlarged and diſtended as a bladder that is blowne vp; what then ſhould diſtend or inlarge this *Pupilla* or perforation, ſayth *Galen*, but onely a ſpirit? And this indeed is his argument whereby he proueth that there is an Animall ſpirit.

The ſpirits of the eie.

For, ſayth he, this amplification or inlargement hapneth becauſe al the ſpirits doe aſſemble themſelues vnto the eye which is open, whereas when they are both open the ſpirits are equally diuided betwixt them. *Galen* alſo prooueth the ſame thing by diſſection; for if you blow vp the grapy membrane on the backſide you ſhall perceiue that the *Pupilla* or perforation will bee inlarged. VVherefore it followeth neceſſarily that all that ſpace which is before the chriſtaline humour is filled with ſpirits and a thinne humour. The thinne humour ſheddeth it ſelfe in all the other parts but in the very *Pupilla* or perforation the ſpirits are gathered together.

The *Pupilla* or Apple of the eie.

This *Pupilla*, is called κορὴ by *Hippocrates* in his Booke *de Carnibus*; by *Galen* in the fourth Chapter of his tenth Booke *de vſu partium* δʹ ιε [Table 3.figure 4.5.6.7.ª] In Latin *Pupilla*, *oculi feneſtra*, the window of the eye, *nigrũ oculi & foramen oculi*, we vſe to call it in our language the Apple of the eye.

It is a hole or perforation of the grapy membrane and is otherwiſe called the leſſe circle of the eye (as the greater circle is called the Rainebow) [Tab 3.figure 2.3.ᵍ] becauſe it appeareth in the center of the eye like a blacke poynt. Blacke (I ſay) as well becauſe of the deepe ſcituation, as alſo becauſe the coates which compaſſe it about are of a darke colour. This hole or perforation is not onely leſſe then the compaſſe of the horne, but alſo there is ſome diſtance betwixt them, leaſt otherwiſe the ingreſſe of viſible images through the horne might be interrupted; wherefore when the grapy membrane commeth to the tranſlucent part of the horny membrane, it is no more round but reflected backeward and inclineth toward the chriſtaline humour, leauing a hole in the middeſt which is called *Pupilla*, as *Varolius* hath elegantly deliuered.

The figure of it.

This *Pupilla* or Apple of the eye is in man and ſome other creatures as Dogges very round: in many bruite beaſtes, as Oxen, Sheepe and Goates it is longer then round, of an Ouall figure or like a circle compreſſed in the middeſt, which compreſsion is dilated or contracted according to the motion, either proceeding from the Animall ſpirite, or from the light: ſo that the figure thereof is ſometimes round, ſometimes long, ſometimes wide, ſometimes very narrow, as in a Cat whoſe *Pupilla* is like a narrow and long cleft; *Aquapendens* ſayeth, that in a Pike it is of the figure of a cone.

How the *Pupilla* is contracted & dilated. *Galen.* *Aquapendens.*

The dilatation and contraction of this *Pupilla* or Apple of the eye, *Galen* aſcribeth to the Animall ſpirits, but *Aquapendens* thinks that the hole of the *vuea* or grapy membrane, (which is al one with the *Pupilla*) is dilated or conſtringed acording to the ſtrẽgth or weakneſſe of the light that beateth vpon it. For in a ſtronger light it is contracted the better to defend the chryſtaline humour, which is oftentimes offended by a ſtrong light. In a leſſer or weaker light it is dilated to helpe the ſight to diſcerne of many viſible thinges, which otherwiſe would not appeare; (And therefore thoſe that complaine of the weaknes of the eyes and ſight muſt haue them viewed rather in an obſcure and darke, then in a Lucide or bright place) and ſo it commeth to paſſe that a ſtrong light doth not offend the eyes, becauſe it is admitted to the chryſtaline humour in a leſſe quantity; nor a weake proue inſufficient

cient becauſe it is receyued in a greater quantitie.

That the motion of the *Pupilla* is not from the Animall ſpirite as from the efficient cauſe he prooueth, becauſe a ſtrong light attenuateth the ſpirits, diffuſeth them, and ſo ſhould conſequently enlarge the *Pupilla*. On the contrary, a weake light doth dull & diminiſh the ſpirits and ſo the *Pupilla* ſhould be ſtraitened, whereas common experience teacheth vs the quite contrary: wherefore ſaith *Aquapendens* I conceiue that the dilatation and contraction of the Apple of the eye proceedeth from a proper faculty of the the Grapy coat, which Faculty notwithſtanding is ſtirred vp by the external light which entreth into the eye, and yet we ſee that in Suffuſions and Catarracts the *pupilla* is dilated and conſtringed when a ſtrong light cannot offend ſuch eyes becauſe it hath no free paſſage, the Catarract or clowd being interpoſed betwixt the light and the ſight: howbeit euen in ſuch Suffuſions if one eye bee ſhut the *pupilla* of the other is dilated, which can be from no other cauſe but onely from the ſpirits.

Obiections againſt *Aquapendens*

The vſe of this perforation or *pupilla* is to tranſmit the viſible images to the Criſtalline humour: for (ſaith *Galen* in the fourth chapter of his tenth booke *De vſu partium*,) vnleſſe the Grapy coate had heere bene perforated all the parts of the eye had bin created in vaine, becauſe the Criſtalline humor hath no communion with his obiectes but onely by this perforation of the grapy Membrane, and therfore according as this apple of the eye is dilated or contracted, ſo do we ſee better or worſe. And hence it was that *Galen* in the ſecond Chapter of his firſt booke *de ſymptomatum Cauſis* hath well obſerued that the dilatation of this Apple of the eye, whether it be an original fault in Nature or happen after by accident, is alwayes a great weakner of the ſight. On the contrarie, the coarctation or ſtraightning of the *pupilla* if it be naturall is the cauſe of the quickeneſſe and vigour of this ſenſe, for when it is notably dilated the animall ſpirit which floweth into the eye cannot fill the whole ſpace which is before the Criſtalline humor; whereas on the contrary when the *pupilla* is contracted or gathered together the ſpace is ſooner fulfilled.

The vſe of the *Pupilla*.

A narrow apple is the beſt ſight. And why

Add heereto that for the perfection of ſight it is very neceſſary that the viſible ſpecies or Formes ſhould flow vnto the eye by a right line and ſo paſſe vnto the Center of the Criſtaline with a pointed angle; for ſo they make the better impreſsion, and therfore the perforation or the *pupilla* is very narrow that the lines produced from the Circumference thereof as from a baſis might touch the center of the Criſtalline in an acute angle; for if the *pupilla* be ſo dilated that the lines produced from the circumference thereof do make a right or obtuſe angle in the center of the Criſtalline then is the ſight not onely offended but aboliſhed.

Hence it appeareth that the naturall latitude or ſtraightneſſe of the *pupilla* maketh much for the ſtrength or weakeneſſe of the ſight, eſpecially if the diſtance betwixte the viſible obiect and the organ of the ſenſe be proportionable. But to return vnto the grapie Membrane, of which this apple of the eye is but a perforation.

This Membrance according to the difference of the parts thereof hath diuerſe colours, for on the outſide where it toucheth the horny Coate it is blacke; on the inſide where it reſpecteth the watery and Criſtalline humours it is black or duskiſh. But where it maketh the greater circle which we call the Rain-bow (according to the diuers temper of the Braine and the eyes ſaith *Laurentius*) it is ſometimes greeniſh, ſometimes sky coloured, ſometimes blacke. Finally, the backward part of this Membrane where it firſt ariſeth from the *Pia mater* is whitiſh; preſently it groweth greeniſh, then neerer vnto a blewe, all which colours may be beſt diſcerned in the eye of an oxe. This black colour (as *Galen* in the third chapter of his tenth booke *de vſu partium*, where hee ſpeaketh of a sky colour becauſe he deſcribed the eie of an Oxe) is very worthy of admiration becauſe there is no ſuch colour found elſe-where in the whole body. And although in ſome eies it is leſſe or more blacke then in others, yet in all it is eyther blacke or browne, that the criſtalline humour being therewith couered might better collect and gather his brightneſſe together. For as a ſmall light in an obſcure and darke place is better perceiued & ſhines brighter then in an open and light place, and maketh thoſe thinges which are about it better to be perceyued; ſo the brightnes that is encluded within the eye becoms more bright, and the viſible ſpecies do better appeare in the criſtalline humour, becauſe the inner circumference of the whole eye is inueſted with this obſcure and darke Membrane, by whoſe ſhadow the criſtalline is compaſſed; ſo that his brightneſſe returning backe

Diuers colors of the Grapie Membrane.

What profite the eie hath by his blacke colour.

How the colour of the inside differeth from the colour of the outside.

backe from the blackeneſſe and obſcurity of the membrane is vnited better into himſelfe. And ſo (as *Aquapendens* hath well obſerued) that light which is but weake, or but moderately ſtrong doth better appeare in the Chriſtalline then that which is much ſtronger, as whereby the inbred light of the humour it ſelfe is ouercome.

Againe, we ſay that the darkeneſſe of the colour of this membrane maketh much to the collection and refection of the ſpirits. For when the Criſtalline is too much affected by a vehement light, then we cloſe our eyes and the ſpirits turning themſelues vpon thoſe darke colours are refreſhed, as before hath bene ſhewed in our Hiſtorie of the horny membrane. Wherefore alſo about the *pupilla* it is thicker, becauſe it ſhould caſt a greater ſhadow vpon the Criſtalline in that place where the light hath his aceeſſe, for on the backeſide it is compaſſed with the thicke and faſt horny coate. And for this cauſe betwixt the horny membrane and the Criſtalline humour this coate is blacke. But this blackeneſſe on the inſide of the coate where it reſpecteth the humours, ſeemeth to bee bred with the coate it ſelfe, but on the outſide where it reſpecteth the horny membrane, I conceiue it is but accidentary becauſe it wold colour a mans finger that toucheth it, and may eaſily be waſhed of ſo that the membrane will remaine white; but the colour on the inſide will not die or taint the finger, for if it were ſo thoſe bright bodies which it reſpecteth and compaſſeth would be foyled by that blackeneſſe, and ſo looſe their purity.

Some are of opinion that this blackneſſe is the thick excrement which is ſeparated in the nouriſhment of the Criſtalline humour, as alſo that the watery humor is the thin excrement of the ſame. Now as this blackeneſſe is perpetuall in all creatures on the outſide of this coate; ſo on the inſide, eſpecially where it reſpecteth the glaſsie humour, the membrane is ſometime browne, ſometime purple or skie coloured (whence it was that *Galen* in the fourth chapter of his tenth booke *de vſu partium*, called it a skie coloured coate) and ſometimes greene as in oxen; but where it is perforated on the foreſide and reſpecteth the ſhining or tranſparent part of the horny Membrane it is not in man of one and the ſame colour; yet ſo that it is alwayes of that colour which we ſee in the Rainbow of the eye, according wherto we ſay a man hath blacke or browne, or skie coloured, or a Goates eye, which ſaith the Phyloſopher is an argument of a good diſpoſition: ſo that the ſame *Ariſtotle* in the fifth booke *de generatione Animalium* and the firſt chapter hath well obſerued that among all creatures onely man hath eyes of diuers colours, for other creatures all of the ſame kind haue eyes alike, excepting horſes, who ſomtimes haue wayle eyes.

A mans eyes of diuers colours.

The Rainebow called in Greeke and Latine *Iris*, hath his name from the ſimilitude of the Rainebow which appeareth in the clouds, becauſe this greater circle of the eye]Tab. 1. fig. 7. 8. f. Tab. 3. fig. 2. 3. f.] is diſtinguiſhed with diuers colours which ſhine through the horny Membrane. *Galen* in the ſecond chapter of his tenth booke *de vſu partium*, ſaith, that in this Rainebow there are ſeuen circles one within another, all differing in thickeneſſe and colour, which proceed from the Membranes. But how nice a peece of buſineſſes it were in diſſection to offer to ſhew all theſe circles diſtinctly without confuſion, ſurely ſo hard a matter it were to accompliſh as vaine when it were performed. Some haue called this *Iris* στεφάνη a *Crowne*.

The Rainbow of the eye.

A nicitie in diſſection.

Diuers opinions of the cauſe of the Rainbow.

There are many opinions of the cauſes of ſo great variety of colours in this circle of the eye, and if you will giue me leaue I will acquaint you with what other men haue conceiued, and then deliuer that opinion which I follow my ſelfe.

Firſt of all therefore *Ariſtotle* in the firſt chapter of his fifth booke *de generatione animalium* maketh mention of *Empedocles* his conceit, who compoundeth the eye of fire and water. The skie coloured eye ſaith he, is when the fire beareth the ſway, and the blacke eye when the water exceedeth the fire.

Empedocles, Ariſtot.

Ariſtotle in the place before quoted refers the variety of the colours to the plenty or ſcarſity of humours, and maketh demonſtration of his opinion by the example of aire and water: for, ſaith he, if you looke vpon a deepe water, or a thicke aire they will ſeeme black and obſcure. But if there be but a little of either, then will their colour appeare blewiſh & bright. This conceit of *Ariſtotles*, *Columbus* reprehendeth, but *gratis*; for he addeth no reaſon againſt him.

Galen.

Thirdly, *Galen* in *Arte medicinali* is of opinion that the plenty of ſplendor and ſcituation the chryſtaline and watery humors is the cauſe of this variety of colours. The eye ſaith he becom-

becommeth skye-coloured, either becauſe of the plentie or ſplendour of the Chryſtaline humour or by reaſon of his prominent ſcituation, whereto hee addeth the paucity and purity of the watery humour. The eye is blacke when the Chryſtaline is little or ſcituated ſomewhat too deepe, or becauſe it is not exquiſitely bright, or becauſe the watery humour is ſomewhat more plentifull and yet not pure. *Veſalius* reprehendeth *Ariſtotle* and *Galen* in theſe words, which indeed are but bare words. This colour, ſayeth he, ariſeth not from the plenty, defect or tenuity of the humours of the eye, neither yet from the collection or dilatation of the Apple, and finally not from the depth of the eye or the tenuity thereof.

Auicen.

Fourthly *Auicen* referres the cauſe vnto the colour of the grapy coate, which as it is diuerſly depainted ſo it bringeth forth in the eye diuers colours: if it be sky-coloured the eye is alſo sky coloured, if blacke the eye is blacke. And him doth *Veſalius* follow.

Aucrboet.

Fiftly, *Auerhoes* imagines that the whiteneſſe of the eye proceeded from cold, and the blacknes from heat.

Varolius.

The ſixt opinion is that of *Varolius*, who ſayth, that the cauſe of the colour is to bee referred to the vnequall plenty of the ſpirit and of the watery humor, which as it falleth in diuers parts of that place ſo it repreſenteth diuers colours. The colour ſayth he which reſulteth from the grapy membrane receding or giuing backe from the horny, is wont to be called the Rayne-bow from a certaine appearing variety: hee calleth it an appearing variety, becauſe in very trueth there is not in that place any true diuerſity of colours but only in apparition, becauſe the horny membrane ſtandeth vnequally aboue the grapy, and ſo an vnequall quantity of ſpirits and humour fall between them.

Archangelus.

The ſeauenth opinion is that of *Archangelus*, who writeth that the diuers colours in the Raine-bow are cauſed by the inequality of the veines which are in the grapy coate (which veines are alſo communicated to the coate called *Aranea* or the cob-web) containing in them blood diuerſly prepared according to the variety of the partes that are to bee nouriſhed, which are much vnlike other parts of the body. Hee imagineth alſo that the grapye membrane is not of one colour in men, that their eies being wearied might bee recreated, eſpecially by greene, of which there is moſt in the world; and hence it is that we doe often ſhutte our eyes, that ſo the ſpirites that are ſpent or wearied may bee reſtored and refreſhed.

Laurentius which is alſo the truth.

The eight opinion is that of *Laurentius*, who referreth the cauſe to the watery and chryſtaline humours, to the variegation or diuers colours of the grapy coate and to the ſpirits, which opinion alſo we will follow as ſeeming moſt reaſonable. For the cauſe of the sky-coloured eye in reſpect of the chryſtaline humour is the plenty thereof, the ſplendor and the prominent ſcituation; in reſpect of the watery humour the ſplendour and the paucity, for when the watery humour is but little it doth leſſe hinder the fulgent brightnes of the chriſtaline.

The cauſes of the skie-coloured eie.

The cauſes of the black eie.

The blacke eye hath quite contrary cauſes, to wit the paucity of the Criſtalline humor his impurity and deepe ſcituation, as alſo the impurity and plentie of the watery humour.

The colours betwixt theſe depend vpon intermediate cauſes.

In reſpect of the grapy Membrane, the colours of the eye do differ, as when it is ſimply variegated or diuerſly ſtreyked then is the eye alſo of diuers colours, becauſe in that place the Grapy membrane is diuerſly diſcoulered.

In reſpect of the ſpirits the colours of the Rainebow differ, for thinne, pure, bright and plentifull ſpirits make it skie-coloured, on the contrary craſſe, impure, cloudy and few ſpirits may be the cauſe of this blackneſſe.

The vſe of the colours of the Raine-bow.

The vſe of this variety of colour in the Rainebow ſome referre vnto beauty, or happely by reaſon of this diuerſity of colours the diuers colours of externall things are there better expreſſed and offered to the Criſtalline humour. But in thoſe creatures which ſee in the night, the *Iris* is only a bright place which if it happen in a man, as *Suetonius* reporteth of *Tiberius Caſar*, he alſo wil ſee in the night.

Finally this grapy membrane ſome of the new writers, as *Fuchſius* and *Aquapendens* imitating the Arabians haue deuided into two partes, the forepart they call *vuea*, and the backpart *Choroides*.

From the circumference of the grapy coate [Table 3. fig. 17.] doe directly proceed certaine ſmall filaments or ſtrings like black lines, which reſemble the haires of the eye-lids. Theſe ſtrings reach vnto the margent or brimme of the chryſtaline humour, and although they be placed in the cob-web yet they compaſſe the chryſtaline humour round about. By

the

the mediation of theſe hairy threds the grapy Membrane is ioyned to the circumference of the Membrane which immediately inueſteth the Criſtalline humor [Tab. 3. fig. 7. 00] and ſo the criſtalline humor it ſelfe is tyed to the neighbour partes: wherefore becauſe it doth the office not of a Membrane but of a Ligament or Tie; *Fallopius* for the forme calleth it *Ligamentum Ciliare* or the hairy Ligament, others call it *Interſtitium Ciliare*, becauſe it diſſeuereth the watry humour from the glaſſy.

Fallopius.

CHAP. VIII. *Of the Cobweb or Membrane of the Criſtalline humor. Of the Membrane which compaſſeth the glaſſy humor, and that coat called* Retina, *or The Net.*

THE Membrane which immediately compaſſeth the Criſtalline humour is called in Greeke ἀραχνοειδὴς, *Aranei-formis*, that is the Cobweb, moſt properly is it called *Criſtalloides* from the humour whoſe proper coate it is, yea the verie ſuperficies of the ſame. Some call it the Looking-glaſſe, becauſe it is bright and tranſlucid. Some thinke it hath his originall from the *Pia Mater*, and of that opinion is *Columbus*. Others from the coate called *Retina* or the net as *Aquapendens*, but *Archangelus* conceiueth that it is made of the Opticke Nerue dilated and drawne out into a wonderfull thinneſſe. But wee are of opinion ſaith *Bauhine*, that it is engendred in the firſt conformation, together with the Criſtaline humor which is framed of the pureſt and brighteſt portion of the ſeed. It is a Membrane moſt thinne (ſo ſaith *Hippocrates* in his Booke *de Locis in homine*) very faſt, moſt light, white, bright and ſhining beyond meaſure, the better to admit the light and to be changed thereby, (for onely this Membrane dooth indeede receiue and apprehend the affections of the light) and leaſt if it had bene thicke it ſhould haue hindred the ſight.

The Cobweb or coat of the criſtalline humor.

Diuers opinions of his Originall.

The ſubſtance of it is much like the inward skinne of an Onion or rather like a ſpiders Cobweb, for the fineneſſe I meane, and not for the denſity or faſtneſſe thereof. This Membrane couereth the criſtalline humor both on the foreſide and the backſide immediately compaſsing and eſtabliſhing the ſame. Although I know that *Galen* in the ſixte chapter of his tenth booke *De vſu partium* writeth, that it inueſteth this humour onelie there where it toucheth the grapie Membrane, with whom *Archangelus* alſo agreeth. But that the whole criſtalline humor might be more fit for ſenſation, it was neceſſary that it ſhould be compaſſed round with this Membrane, which notwithſtanding we acknowledge to bee thicker, faſter and ſtronger on the fore-ſide. For becauſe wee ſee before vs therefore the faculty and power of this ſenſe ought there to bee more vigorous, becauſe in that place the light is more ſtronglye vnited by the roundneſſe of the Criſtalline and the refraction of the watery humors. And therefore *Ruffus* calleth it *Viſus & Pupilla*, the ſight or Apple of the eye. And becauſe in this as it were in a glaſſe the Effigies or Image of the *Pupilla* doth conſiſt, therfore *Galen* in the place next before quoated, calleth it the Idoll or Image of the ſight. On the contrary the backpart of it is looſer, thinner and more rare.

The ſubſtance of it.

Why cleer before.

The vſe of it.

If this Membrane be taken away, the figure of the Criſtalline humor is deſtroyed; for whereas before it was ſmooth, equall and poliſhed; nowe it falleth aſſunder and becommeth vnequall not being able to ſtand togither when the bande which conteyned it is remooued. In a word, the criſtalliue humor receyueth from this Membrane not onelie his ſenſatiue power, nor the forme and figure of his ſubſtance, but alſo his efficacy and virtue. Veynes it hath none, but ſeemeth to be nouriſhed by the Ciliar Ligament.

The coate of the glaſſy humor is called ὑαλοειδὴς, which *Columbus* & *Archangelus* haue confounded with the cobweb before deſcribed. But the trueth is, that their ſubſtaunce is different, for this is thinner then the former and encircleth the glaſſy humor round about leaſt it ſhould either be diffluent or confounded with the watery humour. Other Anatomiſts haue altogether pretermitted the mention thereof, becauſe they think that both humors are involued by the *Cobweb* Membrane. In the middeſt of this coate doth the Ciliar or hairy Ligament appeare.

The coate of the glaſſy humor.

The laſt Membrane or coate of the eye is called *Retina* or *Reti-formis*, [Tab. 3. fig. 8] in Greeke ἀμφιβληστροειδὴς, becauſe it reſembleth a little round caſting Net. This Membrane ariſeth from a part of the Braine deſcending thorough the Opticke Nerue, or if you will, from the marrow of the Nerue it ſelfe as ſoone as the Nerue attaineth to the eye, and ſo hangeth at the very roote of the Nerue, from thence it paſſeth on to the middle of the eie

The Net.

and

eye, and within the cauity of the grapy membrane vpon which it immediatly lieth, but is not tied thereto. It is inlarged and like a net or caule compaſſeth the glaſſy humour, but without any connexion at all, *Aquapendens* ſaith, it is inſerted into the vtmoſt circle of the Criſtalline humour, and that by the meanes hereof the Criſtalline ſwimmeth in the midſt of the glaſſy humour as a peece of wood ſwimmeth in the water. It is ſoft, reddiſh, of a mucous ſubſtance, not ſolid and craſſe as is the ſubſtance of the braine. The ſubſtance thereof.

Wherefore, neither in ſubſtance nor in colour is it like a Membrane, and therefore *Galen* in the ſecond chapter of his tenth booke *de vſu partium* ſaith, it neither deſerueth the name of a membrane nor of a coate, for if you ſeparate it from both the humours and lay it vpon a heape by it ſelfe, [Tab. 3. fig. 8. l.] it will ſeeme to you to be a part of the brain dilated, and therefore *Galen* calleth it the net like body; *Veſſalius* ſaith it can haue no fitter name then the name of a coate, albeit *Columbus* and *Platerus* are not of his opinion. Veins and Arteries it hath very many and conſpicuous; and indeed more (though they be ſmall) then ſeeme conuenient for the proportion thereof: for all nerues being inueſted with a portion of the *Pia mater* wherein veines and arteries doe run, this alſo receiueth a veine & an arterie diuerſly branched, wherby Nature hath prouided and prepared aliment not onely for the Nerue, but alſo for the humours of the eye. In theſe veſſels therefore is blood contained, not thicke nor feculent but thin and fluide, whereby the glaſsie and Criſtalline humours might bee nouriſhed, which becauſe they are pure bodyes do alſo ſtand in need of pure blood. The veſſels thereof. The prouidence of nature.

It is alſo darke and corpulent not tranſlucent, that it might not bee affected or changed by the light.

The firſt and greateſt vſe of this Net-like coate is, ſaith *Galen* in the ſecond chapter of tenth booke *de vſu partium*, that when the Criſtalline is altered, it might apprehend the *Senſation*; or rather to leade along the faculty of ſenſation to the Criſtalline humour, becauſe as we ſaid euen now, it ariſeth from the ſubſtance of the nerue. The vſes of it

Another vſe of it is, that the viſiue ſpirits might bee diffuſed through the Criſtalline humour and the whole eye; to perceiue the alterations of the Criſtalline and to tranſport the images of viſible things to the braine as to a iudge.

Finally, whereas it intercedeth betweene the Grapy membrane and the glaſsy humor it keepeth the pure ſubſtance of the glaſsy humor from being defiled with the blackeneſſe of the Grapy membrane. And ſo much concerning the membranes or coates of the eye. Now we proceed vnto the humours.

CHAP. IX. *Of the humours of the Eye,*

The humors which are the moſt noble parts of the eye are contained within their coates, and are three; differing each from other in figure and conſiſtence; yet all bright and perſpicuous, diſtinct in their ſeates, filling the cauities of the eye, and helping the action of the ſight. Theſe three humors are called the Watery, the Criſtalline, and the Glaſsy, amongſt which the Criſtalline excelleth in dignity and vſe and therefore is called the ſoule, the center and an inner Spectacle of the eye. The three humors of the eye.

The watery humour [Tab. 3. fig. 10. and 16. y, and 19.] is called in reſpect of the other *humor tenuis* the thin humour, and by ſome *Aqueus*, becauſe it is fluide like water and alſo tranſparent. And hence haply it was that *Ariſtotle* maintained againſt *Plato* that the eye was not fiery but watery. It is alſo called *humor Albugineus*, becauſe the colour and ſubſtance thereof is much like the white of an egge. This is the vtmoſt of all the humours filling the whole ſpace which is betwixt the foreſide of the criſtalline, the grapy membran which is there duplicated, and the horny membrane; ſauing that it is accompanied with an aiery and bright ſpirit. The watery humor. What place it hath in the eye.

It is diſpoſed on each ſide the apple of the eye, ſtable and not moueable, becauſe it hath in it a kinde of *Lentor* or ſlimineſſe. It is but litle (wherein *Veſſalius* was deceiued) filling ſcarſe the tenth part of the circumference of the eye. In this humour are thoſe Suffuſions made which they commonly call Cataracts. Where cataracts are.

The vſe of it is very notable, as we ſhall heare afterward, which hath mooued vs to doubt whether it be a part generated of the ſeede as the other humors of the eye are, or an excrement ſegregated or ſeparated in the nouriſhment of the criſtalline humour as *Galen* hath written in his booke *de Anatomia viuorum* in the chapter of the eyes, and after him

Columbus, *Varolius* and *Aquapendens*. *Auicen* alſo is of the ſame minde, ſauing that he cals it the excrement of the glaſſy humour. And this doubt is further increaſed, becauſe wee learne out of Anatomy that this watery humour is diſtinguiſhed from the criſtalline by the cobweb-like membrane, and therfore ſhould ſeeme not to bee the excrement thereof but a part by it ſelfe. Whether it be a ſpermaticall part or an excrement.

But becauſe no ſpermaticall part being taken away can be regenerated, whereas wee know that in wounds of the eie this watery humor may be totally loſt & yet regenerated again, we are in doubt vppon what we ſhould reſolue. *Columbus* ſaith, that twiſe he ſaw this watery humor loſt and recouered againe ſo as the patient could ſee with the ſame eye. And *Varolius* affirmeth that he hath ſeene as much. Theſe learned and curious Anatomiſts account it but an excrement, which in many diſeaſes is much waſted as *Platerus* admoniſheth vs. But *Laurentius* will haue it to bee a liuing and ſpermaticall part of the eye, not an excrement, becauſe it perpetually keepeth the ſame figure, purity and quantity. Beſides, it is a defence for the Criſtalline, and like a ſpectacle carrieth the images thereto. If it iſſue out of the eye it can hardly be reſtored, it extinguiſheth the ſight, and finally betwixt it and the Criſtalline nature hath interpoſed a membrane.

The Criſtalline humour [Tab. 3. fig. 11. 13. 14.] lyeth vnder the former; ſo called becauſe it is exceeding bright like pure Criſtall in ſplendor and tranſparancie, but not in conſiſtence and hardneſſe: and therefore *Hippocrates* in his book *de carnibus* calleth it *Diaphanum oculi*, *Ariſtotle* in the 9. chapter of the firſt booke *de hiſtoria anim.* and in the firſt chapter of the fifth booke *de generatione animalium* called it κόρη the *Pupilla* or Apple of the eye. This humour is a *Similar* part of the body and made of the moſt pure and lucide portion of the ſeede and the ſincereſt or pureſt of the mothers blood. That it is a part may be proued as well by the authority of *Galen* as by reaſon: *Galen* in his ſixt chapter of the firſt of his Method and in the firſt booke *de cauſis Symptom.* reckoneth it among the parts. The criſtalline humour. Whereof made.

Beſide the definition of a part as well generall as ſpeciall agreeth well thereto, for it is generated in the wombe together with the other parts. It hath a proper circumſcription, it liueth. It is nouriſhed and performeth an Act or an office: wherefore *Galen* accounteth both this and the glaſsy humour among the Similar parts. This humour in men is ſcituated right before, [Tab. 3. fig. 1.ª.] for the membrane which containeth it cutteth the eye into two vnequall parts, the forepart being foure-fold leſſe then the backepart. Furthermore, it approches nearer to the inward angle of the eie then it doth to the outward.

The reaſon of this poſition is, becauſe it was neceſſary that ſome bodyes ſhould be placed before it, others behinde it; ſome of them to be ſeruiceable vnto it, ſome of them to defend it, and ſome of them to lend it their aſsiſtance: but in Oxen it is nearer to the lower part of the eye.

It is compaſſed by the cobweb-like membrane which, as we ſaid, before is faſt and poliſhed but behind more laxe and rare: when this Membrane is taken of the ſubſtance of, the Criſtalline humour offereth it ſelfe to our ſight, which is wateriſh indeed, but not fluid much like water lightly frozen into a tender yce; and when the membrane wherby it is knit together is remoued, it falleth to the ſides and ſlideth a little downe. This humour on the foreſide is compaſſed with the watery humour, [Tab. 3. fig. 10. & 16.] on the backſide it ſitteth or ſwimmeth rather in the glaſsie humour as a bowle ſwimmeth in the water. [Tab. 3. fig. 10. and 12.

It is deuoyde of all colour, for if it had bene red or yeallow all things that are ſeene would haue appeared red or yellow, as it happeneth with thoſe that are troubled with the laundies: wherefore, that it might ſuddainely receiue all kindes of colours which are caſt vpon it, it ſelfe is of noe colour at all but cleare bright and perſpicuous that it might bee altered and changed by the light. For this is the onely cauſe why euery colour hath power to make alteration therein, yea this humour alone is altered by colours and receiueth the images of viſible things. Yet is it not perſpicuous or tranſparant after the ſame manner that the watery humour is perſpicuous and tranſparant, becauſe in it there is made a new refraction of the light: wherefore it is faſter or more denſe that the light in his ſuperficies might bee broken *ad perpendiculum* or with a right line, for ſo the light is better vnited and ſtrengthened. It is moderately hard that the images might be faſtened therein, and thick yet ſo that it is tranſlucide, that the light may paſſe through it. It is ſmooth and notable ſlippery and yet with the ſoftneſſe it hath a *Lentor* or ſlimineſſe, ſo that if you preſſe it it will cleaue like Glue to your fingers. The magnitude of it is much like a The poſition. Why it hath no colour. The magnitude & figure.

lupine or ſmall peaſe. The figure ſomewhat flat like a greater Lentile: whence *Aetius* calleth it φακοειδὴς *Lenticularis.*

Before it is almoſt plain, yet a little riſing like a Lentile the better to receiue the ſplendor or brightneſſe of the light. Backeward it is ſpherical or round that it might more ſafely reſide in the glaſſy humour. At the ſides it is ſomething protuberated: but becauſe it ſhould not fall out of his ſeat but hang ſuſpended as it weere in the chamber of the eye: it is ioyned to the grapy membrane by the *Ciliar* or hairy ligament, yet that onely in the greateſt circumference of the chryſtaline: but before and behinde it is free, that it might not intercept the continuity of the tranſlucid bodies.

The 3. humor called *vitreus.*

The third and laſt humour of the eie is called *vitreus*, [Table 3. fig. 1.[b] figu. 18. and 20] or the glaſſy humour, becauſe in conſiſtence and thicknes it is like to melted glaſſe, in colour and brightnes to glaſſe when it is cold. It is ſcituated in the backepart of the eye eſpecially: ſomewhat alſo before, inſomuch that it filleth the parts of the cauity of the eie if it were diuided into foure [Table 3. figure 10. and 20.[x]] and is foure times as much as is the chryſtaline, the better to containe the ſpirits of the ſight that they ſhould not too ſoone be diſſipated.

His ſcituatiõ.

Conſiſtence.

The ſubſtaunce of it hath a kinde of conſiſtence, eſtabliſhment or firmitude in it; yet is it farre ſofter and thinner then is the chryſtaline that it might better giue way thereunto, for the chryſtaline is ſeated therein: notwithſtanding it is not ſo fluide as the watery humour. The ſplendour or brightnes of it is equall to that of the chryſtaline; for ſayth *Aquapendens* they are both of a moſt exquiſite purity, tranſparancy and brightnes.

And figure.

The figure as it is in the eye reſembleth the better part of a bowle cut in ſunder, [tab. 3. figure 9. and 20.] for the backeward ſurface is round or conuex: the forward is plaine, yet in the middeſt thereof hath it a boſome [Table 3. figu. 9. r and 18. β] whereinto it receiueth the chryſtaline humour. And although it be compaſſed about by the net-like coate called *Amphibleſtroides* whereby it is nouriſhed from the veines diſſeminated there through; yet notwithſtanding it hath a proper coate of his owne called *Vitrea*, which if it be broken this humour preſently melteth and reſolueth into water.

CHAP. X. *Of the vſe of the Humours of the Eye and of the Sight.*

A philoſophicall diſcourſe of the vſe of the eie.

HAuing declared the admirable wiſedome, prouidence and goodnes of God our Creator in the conformation of this diuine member which wee call the Eie: although we haue ſpoken ſomewhat in the Hiſtory of euery particular part concerning their vſe, yet there remaine many things worthy our obſeruation touching the humours, which being ioyned to that that hath bin ſayd before will better abſolue and accompliſh this diſcourſe of the vſe of the eye and the true manner of ſight. Which though I muſt confeſſe that they are more Philoſophicall then Anatomicall, yet becauſe they pertaine to the ſame ſubiect, I preſume the Reader will not abhor from them.

The proper obiects of the ſight, Common.

That the Eyes are the inſtruments of the ſight by which it perceiueth all viſible things as well Proper as Common there is no man ignorant; Proper as all colours, Common as the figure, magnitude, number, motion and ſcite, which are ſenſible qualities common to all the Sences; ſo that it is truely ſayed that the Eye ſeeth not a *Man* but thoſe thinges which are viſible in *a Man*, as colours together with the ſcite, figure, magnitude, number and motion of his partes, out of which afterward the Soule collecteth that that thing is a Man.

Particular vſes of the parts.

The Eie is framed of many parts, all which were created for the vſe of the ſight. But becauſe in euery organ which is compounded of many parts, there is one ſimilar particle vpon which the action of that organ doth eſpecially depend, it would be knowne what this particle is in the eye: we anſwere that it is the Chryſtaline humour which is the authour of the action, becauſe in it the ſpecies or formes of viſible thinges are receiued and by it iudged of.

Beſide this, there are ſome particles without which the action cannot be; as the optick nerue which leadeth along the faculty vnto the chriſtaline; ſome alſo by whoſe helpe the action is made more perfect, as the membranes and the muſcles: and finally, ſome particles are ordayned for the conſeruation of all theſe, as the Eye-liddes and the partes about them.

Seeing therefore the faculty is deriued from the braine by the opticke nerues vnto the eyes,

eyes, which are set as scout-watches to take knowledge of the ariuall of outward thinges; that they may better apprehend the knowledge of such outward obiectes, it was necessary that whatsoeuer is to be perceiued should touch the nerue: for *Aristotle* sayeth in his third Booke *de Anima, That euery action is made by contaction.*

This contaction is here made by a *medium* or meane; for the Sences doe perceiue their obiects through a meane. Wherefore seeing the nerue is separated from the visible obiect, that there may bee sight it is necessary there should bee a contaction either of the nerue to the obiect or of the obiect to the nerue, or else that either of them should be moued in a certaine proportion to the other. All sense is by contaction.

The two first wayes it cannot be, as euen Sense it selfe teacheth vs, and therfore it must be done the third way. If vision be made the third way, then either something must proceed from the nerue to the visible obiects, or on the contrary something must be sent from the obiects to the nerue, or else both must be: that is, Sight must bee made either by an emission of spirites, or a reception of beames, or else by emission and reception both together, How many wales contaction is made,

Now the spirit is not carried from the nerue to the thing that is to bee seene, for then it would follow that the nerue alone by which the faculty yssueth can absolue and perfect the action of sight, and the iudgement should be made without the eye. Againe, neither is there any corporeall thing transported from the body which is sent vnto our eyes; for then the obiects by continuall diffusion would be diminished. Neither is Vision made the third way, so that a spirite or a beame or a light should yssue out of the Eie vnto the obiect and againe something of the obiect should be moued vnto the spirite, that so the contaction might be made in the middle; for then the nerue alone would haue sufficed for the action, and the iudgement should haue beene made without the eie. VVherefore we thinke with the Philosopher that this contaction is made by a *medium*, so that a certaine quality with some colour affecting and changing the ayre that is cleare and lucid betwixt the eie and the obiect, doeth transferre from the things themselues the visible *species* by one right line from the obiect to the eyes, yea to the center of the chrystaline humour. So the ayre which is in the middest betwixt the eye and the obiect leadeth along that which is perceiued, and first of all the colour; for the ayre is altered by colours which it receiueth by contaction; for euen as the Sun attayning by the brightnes of his light vnto the Element of the ayre illustrateth the same; so coulours when they touch the ayre make a kinde of impression therein, for the ayre is alwayes capable of colours when it is cleare, light and illustrated by the brightnes of the Sunne beames. Vision therefore or sight is made by the Reception of visible forms, when the light affected with those formes entreth into the eies through their transluceid bodies; first of al with right beames, afterward diuersly refracted or broken and affecteth the chrystaline with some colour, which chrystaline as the primary instrument of sight doth in an instãt receiue those visible formes whereof refraction is made in the membranes, perfection in the coniunction of the Opticke nerues, and finally a perception in the braine. For the light is the proper obiect of the sight whereby it is moued and affected; Light I say stayned with the formes of colours and externall light, for the eie of a man hath not in it any In-bred light, for then he might see in the darke by sending out a light from his eye. Albeit *Suetonius* reporteth that *Tiberius Cæsar* had such an eye, and that excellent Philosopher and Physitian *Cardan*, as also *Iohn Babtista Porta* of *Naples* do affirme the same thing of themselues. Some creatures there are we know which see worse in the day time then in the night, and therefore they seeke their food in the night season. How sight is made. Whether in mans eie there be an ingenit light. *Tiberius Cæsar Cardanus. Ioh. Bap. Port.*

Nowe because the light thus affected with the images of visible thinges must passe through a refraction of his beames, it is necessary there should bee diuers transluciide bodies. First the ayre through which it attayneth to the eye, then water in the eye in which this refraction might be made. *Plato* indeed (who thought that sight was made *extramittendo*, or by an emission of light out of the eye) thought that the nature of the eie was fiery, yet not such a fire as would burne but onely illustrate; for, sayth he, there is a threefould fire: one shining and not burning, another shining and burning, and the third burning and not shining. But we are taught by Anatomy & by the whole composition of the eye, that the instrument of sight is watery, and therefore *Hip.* in his book *de locis in homine*, saith that the sight is nourished, that is, increased by a moyst brayne. And hereto also may we adde reason, for it is the property of water to receiue; wherefore seeing the formes and images of *Plato* thought the eie was firie. A threefold fire.

outward obiects must be receiued it is necessary that there should be water in the eie.

How the formes are retained.

But because these visible formes should not onely bee receiued, but also retained in the eie, it was necessary that the body of the eie should bee made not onely translucid but also dense and fastly compacted: wherefore Nature did not only make the eye watery that there might bee a refraction, but also that this refraction might bee manifould shee hath created translucid bodies of diuers consistences; for the watery humour is indeed translucid and admitteth the light yet the *Diaphanum* or transparancie thereof differs from the transparancie of the horny membrane that there might bee also a different refraction; this refraction is made from a perpendicular and is in the eie foure-foulde. The first is from the ayre into the horny membrane which is a faster *Diaphanum*. The second from the horny membrane into the watey humour which is a thinner *Diaphanum*; in this watery humour the light is vnited and made stronger, so that it is able to pierce through the third *Diaphanum* which is the christaline humour, wherein as in a faster substance the light is yet more strongly vnited and so passeth on to the last refraction at the glassy humour of which wee shall speake by and by. And as in the eye naturally disposed there are foure refractions, so in the spectacles which make the obiect both larger and brighter there are sixe. For first of all the light entreth into the spectacle which is a thicker *Diaphanum* from the ayre which is a thinner, from the spectacle before it come to the eye it passeth through the ayre again which is a thinner *Diaphanum* into the horny membrane which is a thicker; from the horny membrane into the watery humour which is a thinner *Diaphanum*, from thence into the chrystaline which is a thicker, and finally into the glassy humour so that it proceedeth by course out of a thinner *Diaphanum* into a thicker.

That there are 4. refractions of the light in the eie.

6. in a paire of spectacles,

Another vse of the watery humour,

Another vse of the watery humour is to fill vp the empty space betwixt the christaline and the forward membranes, as also to keepe the horny membrane streatcht or tentered & moyst least if it should grow dry it might be corrugated or wrinkled, and so become thicker and hinder the reception of the visible formes.

A third,

Thirdly, the watery humour sayth *Galen* in the sixt Chapter of his tenth Booke *de vsu partium*, keepeth the horny membrane, the grapy membrane and the chrystaline from exiccation: because the moysture thereof keepeth the transparant without which there could be no vision at all, for we see that in compunctions or wounds of the eye; when this watery humour is let out and dryed vp, the horny membrane which before was turgide and full falleth into it selfe and becommeth darke and rugous.

A fourth.

The fourth vse of the watery humour is to be a defence vnto the chrystaline, least the horny membrane should touch the chrystaline through the *Pupilla* and offend it with his hardnesse.

A fift.

The fift vse is to restraine the impetuous or violent occursion or confluence of externall colours vnto the chrystaline.

A sixt.

And finally to eleuate or lift vp the formes of visible things as spectales doe, that they might be more fully and directly perceiued by the sence. For when the images of externall thinges are ariued at the narrow hole of the *Pupilla* they are lifted vp and so exhibited in the watery humour, wherein they are made more perspicuous; and this indeede was the chiefe reason why Nature placed so pure and neate a humour before the christaline, which is the prime instrument of the sight.

The vse of the christaline humour.

The vse of the chrystaline humour is to be the first and chiefe instrument of the Sight, as wherein it is perfected, and therefore some haue called it the Idol or image of the sight, and *Aristotle* calleth it *Pupilla*, haply because we see especially right before vs. That it is the chiefe instrument of sight may thus bee demonstrated. The Philosophers say, *That whatsoeuer is made to receiue any thing must be vtterly free from the Nature of that which it is to receiue, because the same thing can neither worke vpon it selfe, nor suffer from it selfe.* VVherefore that which is the proper Organ or instrument of Sight must haue in it no colour at al, because it is to receiue all colours. And indeed hereby may wee perceiue a thing to bee without colour, when if it bee placed against any colour it representeth the same, as it is in ayre, water, chrystall and such like: wherefore the instrument of sight must either bee ayrie or watery, or chrystaline.

An axiome in philosophy.

Ayrie it might not be, because the colours that are receiued in the ayre do flow through it, making no mutation at all therein; but we know that the instrument doth only then perceiue & apprehend the obiect when it so suffereth therefrom that it is made the very same; seeing therefore that the colours doe passe through the ayre and make no mutation therein,

in, it could not be that the instrument of Sight should be airy

In the second place it could not be watery, for though the species and formes of colours make a deeper impression in the Water then they do in the Ayre: yet are not the colours therein so imprinted that a man may behold them in it, but they flow through it also. It remaineth therefore that the instrument of sight must be Cristalline, because that onely can receiue and retaine the visible formes. And this also may bee proued by *Autopsie* or ocular inspection, for if you take a beade of Cristall and set it opposite against a coloured body, which way soeuer you looke you shall see the colours in the cristall, as if the cristal were of the same colour, & did not receiue the impression thereof from those coloured bodyes. Wherefore in the cristalline humor colours are not onely receiued but also so retayned that the power thereof is changed into the colour which it receineth.

Nor watery.

But cristalline

And the reason hereof is, because there is in the cristalline not onely a watery moysture, but also a glutinous or slimy, which with his lentor and tenacity retaineth the images or formes of the colours.

The chiefe instrument therefore of Sight Nature hath placed within the eye, a round and glutinous humour most like vnto cristall to receiue and retayne the representations of all colours. This cristalline humour if you duely consider when it is taken out of the eye you shall perceiue it hath no colour in it, but will represent any colour layde neere it, as if it were of the same colour.

Moreouer, if you cut this cristalline humour in sunder, you shall finde that it is made of a glutinous and slymy moysture. And because sensation is a kind of reception, therefore was the Cristalline made round.

The action also of the Cristalline humour is assisted by the cobweb-like mẽbrane which compasseth it about, for if you take out the cristalline humour compassed with his Membrane and lay it vpon a written paper, the letters vnder it will appeare much greater then indeed they are, from whence haply came the inuention of Spectacles, and indeed this humour is a very spectacle to the Opticke nerue, gathering the species which fall vpon it and representing them in a larger forme vnto the nerue.

The cristalline humour is a spectacle to the nerue.

Sight therefore is perfected and absolued, both by alteration & apprehention or discerning. The alteration is made in the Cristalline by reason of the transparencie therof; yet is this transparancie of another kind then that of the watery humour, that it might bee both altered and also changed by the light. For that the impression might be more firme, it is thicker then the watery humour, that in the superficies thereof the light might bee broken *ad perpendiculum*: for so the light is stronger vnited and corroborated when the beames are obliquely shed abroade and yet meete together againe into one because of their refraction; wherefore the Cristalline humour is thicker then the other transluicide bodies that are in the eye, as the horny membrane, the watery and glassy humours; because it was made not onely to returne and giue way to light and colours, but also to deteine them, to suffer from them, and to receiue a sensation of visible things: for the thicknesse thereof prohibiteth the transition or vanishing away of the formes which are fixed in the superficies and body therof. For sense is not made without passion or suffring: now it could not suffer vnlesse the action of the Agent had bene receiued vnto it. Notwithstanding, it is not so thicke or hard that the species or formes could not be imprinted therein, but soft like vnto waxe and viscid that they might cleaue faster thereto. Hence it commeth to passe, that when a strong light, as that of the Sunne, beateth vpon the Cristalline it is pained and offended, because the image of the light maketh a kinde of abode therein. But naturally the image of visible things are no longer retained in the Cristalline then is necessary for their perception, but giue way to others: otherwise the sight would be imperfect: for before the former images be vanished the succeeding cannot bee admitted, because the alteration remaineth in the Cristalline vntill the representation acquit the place when: that is gone the alteration vanisheth together with it, and so there is way made for a new alteration.

How sight is perfected,

Why the cristalline is thicke.

Why soft

The conformation also of the Cristalline helpeth much to make the sight perfect, for example. It is smooth and polished, that the formes therein might be most like to the bodyes from which they are diduced. It is round that the light and the perpendicular beames thereof might in it be better vnited, and againe, that the light might be gathered in his superficies where the sensatiue faculty is the strongest, for so the formes euen of the greatest obiects are conuayed whole vnto the Organ. Notwithstanding on the foreside this

The reason of the conformation of the cristalline.

round-

roundneſſe is ſomewhat depreſſed, which depreſsion helpeth much the reception of the formes. On the backeſide it is rounder that the light beeing brought vnto the Criſtalline might be vnited in it ſelfe and not diſparkled but determine and ſubſiſt in the glaſſy humour.

The reaſon of his conne-xion.

The Criſtalline humour alſo before and behind is at liberty or free from connexion, that the light which entereth alway directly, might haue free paſſage through all the tranſlucide bodyes of the eyes; for by this meanes whatſoeuer is betwixt the Criſtalline humor and the thing ſeene is continuated by a continuity of tranſparancy. Yet ought it not to be on euery ſide looſe, becauſe then any extraordinary motion might haue violated the frame of the eye. Nature therefore hath tyed it in his circuite to the neighbour partes,

The vſe of the the glaſſy humour.

and ſcituated it in the middeſt, that it might receiue the ſeruice & miniſtery of all the reſt.

The glaſſy humour is ſeated after the Criſtalline, leaſt if the light ſhould haue paſſed on to the Net-like and Grapie Membranes which are coloured, it ſhold haue returned againe to the Criſtalline defiled with thoſe colours, and ſo the ſight haue bene forſtalled by thoſe inward colours which are neereſt vnto it. Againe, at this *Diaphanum* of the glaſſy humor there is a new refraction made of the light, not ſuch a refraction as is in the Criſtalline wherby the light is more vnited, but becauſe the ſubſtance of the glaſſy humor is more rare and thin the light therein is diſperſed and weakned, ſome ſay alſo vaniſheth, others that it reacheth from thence into the cauity of the Opticke Nerue where the ſight is perfected; and ſurely the fineneſſe of the net-like Membrane is not able to returne the light that beateth againſt it, but rather giueth way thereto.

Galens credit redeemed by a diſtinction.

Another vſe of the Glaſſy humour ſaith *Galen* is to nouriſh the Criſtalline, which it doth *per Diadoſin* or tranſumption; for he thought that the Criſtalline humor could not be nouriſhed by blood. But to ſaue *Galens* credit, we muſt heere diſtinguiſh, for al parts are nouriſhed by blood; now the Criſtalline is a part and therefore it is nouriſhed with blood. We anſwere, that it is not immediately nouriſhed with bloode but mediately, for becauſe there are no Veines neither in the criſtalline nor in the glaſſy humors (at leſt that the ſight of man is able to apprehend) blood cannot be conueyed vnto them; neyther indeede ought it, leaſt it ſhould haue infected the Criſtalline with a redde colour,

How the criſtalline is nouriſhed.

which woulde haue bene a great hindrance to the ſight; for it behoued aboue al things that the criſtalline ſhould be free from all colour, becauſe it was to receiue all. Wherefore it was neceſſary that his Aliment ſhould be prepared and not conueyed vnto him before it were fitted for his vſe.

The blood therefore conteined in the Veines of the Grapy Membrane in which it is thicke and blackiſh, is powred foorth into leſſer branches running through the Net-like Membrane, where it receiueth an alteration becomming very thin and of a cleare ruddineſſe, which blood is receiued by the glaſſy humor therein prepared and made a fit Aliment both for it ſelfe and for the criſtalline. Hence it is that *Galen* ſaith, *The Glaſſy humor to the Criſtalline is like the ſtomacke to the Liuer.*

But becauſe Anatomiſtes are of diuers opinions concerning the nouriſhment of the Criſtalline humour, it ſhall not bee amiſſe to giue you a taſte of euery mans apprehenſion in this matter, eſpecially of thoſe that are accounted Maiſters in Anatomy.

Diuers opinions concerning the nouriſhment of the Criſtalline humour.. *Galens* opinion.

Galen therefore in the firſt chapter of his tenth Booke *De vſu partium* ſayth, that the Criſtalline humour is nouriſhed by the glaſſy, and the glaſſy by that bodye which compaſſeth it about, to wit, the Net-like Membrane, and that *per Diadoſin* or Tranſumption of matter, becauſe (ſaith he) the criſtalline humor which is white, cleare and reſplendent ought not to be nouriſhed by blood, as whoſe qualities doe differ much one from the other, whereas the aliment ſhould be familiar to that which is nouriſhed thereby. Nature therefore prepared for it a proportionable aliment, to witte, the glaſſye humour, which glaſſy humor by how much it is thicker and whiter then blood, by ſo much doth the criſtalline humour exceede it in humidity and whiteneſſe, for this criſtalline is exquiſitely white and moderately hard.

Varolius.

Varolius enclineth to *Galens* opinion, his wordes are theſe or at leaſt to this purpoſe: Euery thing is nouriſhed by ſuch a ſubſtaince as determineth neareſt vnto that which it ſhould nouriſh; and therefore the glaſſy humour is immediately placed behinde the criſtaline, and is of a ſofter and a thinner conſiſtence. Alſo becauſe ſo noble a part which needeth ſuch abundance of ſpirits by reaſon of their continuall expenſe ſhold not at any time be defrauded of nouriſhment, Nature made ſo great a quantitie of the

glaſ-

glassy humour, in which nutrition the Chrystaline turneth into his owne nature the thicker parts of the glassy humour because it is farre thicker and faster then it. But the thinner part of the glassy humour she separateth as an vnprofitable excrement from the Chrystaline, and thereof maketh the watery humour. Thus far *Varolius*.

But sayth *Archangelus* (who thinketh that the Chrystaline is so nourished with the glassie humour as a bone is nourished with the marrow) if the chrystaline and glassy humours be parts of the body then one part shall nourish another? But it may bee answered, that there is a surplussage of the nourishment of the glassye humour which is a conuenient Aliment for the chrystaline. Another question may be asked, sayth he, how *Galen* sayth that in the glassy humour there is no veine? It is answered that there is no veine conspicuous, but yet there are very many which are so slender that the eye cannot discerne them, and hence it is that the glassy humour is not so white as the chrystaline, because it is sprinkled with many blinde veines. In like manner in the white of the eie which is called *Tunica Adnata*, there appeare no veins at al, but if the eye be inflamed then many veines which before lay hid doe rise vp and become conspicuous. If the braine of a man bee dissected, there appeare no veines therin, but if it be inflamed then, sayth *Archangelus*, may an infinite multitude be perceiued to run through his substance. *Archangelus.*

Laurentius conceiueth that the glassy humour is nourished by bloud, and receiueth small veines from the *Ciliar* or hayry crown; and that the glassy humour prepares the bloud for the chrystaline, which bloud it changeth least the purity of the chrystaline should be infected, but he doth not thinke that the substance of the glassy humour is conuerted into the chrystaline and assimilated thereto. *Laurentius.*

Aquapendens his opinion is, that the christaline is nourished by bloud, and that as bones and membranes which are very white and farre remooued from the Nature of bloud by a propriety of their temperament doe change the bloud into their substance: so it commeth to passe in the chrystaline humour; and that the bloud is conuayed out of the veines of the grapy into the net-like coate and there depurated that it might better be conuerted into the nitid and pure substance of these bodies. The thicker part is thrust downe into the grapy coate and there collected. The thinner part maketh the watery humour. Neither doth he thinke it possible the Chrystaline should be nourished by the glassy humour, *per Diadosin* or Transumption, because the cobweb like membrane commeth betweene the two humours, which *Galen* was ignorant of, who thought that the forepart only of the Chrystaline was couered, and from that mistaking fell into that errour of nourishment by Transumption. And so much concerning the nourishment of the humours. *Aquapendens.*

Two other vses there remaine of the glassy humour, the one to retaine the spirites for the illustration of the Chrystaline; the other to defend it from the hardnesse of the membranes, and to make it a seat wherein it might securely rest it selfe. Other vses of the glassy humour,

CHAP. XI. *Of the outward Eares.*

HAuing thus absolued the History of the Eye, it followeth that wee come vnto the organ of Hearing, which *Aristotle* calleth *Sensum disciplinæ*, because it was created for the vnderstanding of Arts and Sciences: for Speach, because it is audible, becommeth the Cause of that we learne therby as the Philosopher saith in the first Chapter of his Book *de Sensu & sensili*. This instrument of the Hearing is the Eare, framed by Nature with no lesse Art then the former. Yea so full of intricate Meandersis it; that it wil be very hard to be discyphered, so many & so smal are the particles therof, and couched so close in narrow distances or nookes betweene the bones. Notwithstanding we will endeuour our selues for your satisfaction to acquaint you what wee haue learned, as well by dissections as out of the writings of learned men, especially *Fallopius*, *Eustachius*, *Veicherus*, *Arantius*, *Aquapendens* and *Placentinus*. But in the pursuite of this so difficult a taske, we stand in neede and doe implore the helpe of Almighty GOD, that hee would set an edge vpon my wit, saith *Bauhine*, to find out the myracles of his Creation, the Diuinity of his wisedome, and the infinite goodnesse wherewith he hath compassed vs on euery side. Moreouer, that he would giue me power perspicuously to propound and lay open to your capacities a thing so diuersly and quaintly folded vp, that the Eie is scarce able to follow the traine thereof. The history of the eares very difficult to expresse.

These instruments are called in Greek, ὦτα & ἀτα, in Latin *Aures ab hauriendis vocibus*, as sayth *Lactantius*, in English *Eares of hearing*. The names of the eares.

There

There are many parts of the Eares which serue as well for the reception of the sound into them, as also for the *intension* thereof. Some of them are such, as without which there is no reception of sounds, others are necessary for better reception and hearing. Finally, others were created for the conseruation of all the rest. Wee will diuide the Eare according to *Hippocrates in Coacis* into an outward and an inward Eare, and first we will entreate of the outward.

The reasons of the name.

The Eares saith *Aristotle* are parts of the head by which we heare, and therefore it may be immagined they are called *Aures quasi audes, ab audiendo* from hearing. Instruments they are of Hearing indeede, as *Galen* confesseth in the second chapter of his Booke *De Instrumento Odoratus*, but not the principal organs, because if the Eares be cut off close by the heade, yet a man will heare notwithstanding, as if the nose bee cut off a man shall smell though imperfectly.

The reason is, because the principal instrument both of Hearing and of Smelling lies hid within the scul. The outward Eares therefore are helping causes, and when they are sound and whol they are of as great vse for the Hearing, as the nosethrils are for the Smelling.

These outward Eares properly called *Auriculæ* are in men & beasts conspicuous, but in Birds and Fishes it is not so, for Birds haue onely holes whereby the sound entereth into their Brains, because their skinne being harder they want matter whereof this Eare should be framed; beside such eares as other creatures are furnished with would haue beene a hinderance vnto them in their flight, as wee see a contrary winde blowing vpon a saile staieth the course of a Ship: as for Fishes no man that I know hath yet found out the instruments of their Hearing. Those holes which are placed before their eyes we doubt whither they serue for Hearing or for Smelling.

What creatures want outward eares,

The outward Eares are placed in the same paralel or line with the eyes, yet not so much for the better reception of sounds, which saith *Cicero* in his second booke *De Natura Deorum*, of their owne nature do ascend vpward because they haue their consistence in the aire; but rather from the commodity of those softe nerues within the scull which were to communicate the animall spirit dispersed through the substaunce of the Braine vnto the principal Organ of Hearing. Otherwise if the eares had their scituation onely for the apprehension of sounds, they might as well haue bene placed in any parte of the creature as where they are; because the sounds are equally communicated to the whole aire that compasseth vs about. But on the foreside they might not be placed, because that roome was to be taken vp for the eies and the instruments of other senses. For the Eies, because we see by a right line; but we may heare as wel on either side as directly forward, as *Aristotle* saith in the tenth chapter of his second booke *de Part. Animalium*; although I am not ignorant that *Galen* in the eight chapter of his tenth booke *De Vsu partium* is not altogether of *Aristotles* opinion.

The reason of the situation of the Eares.

Againe for the Mouth, partly for the commoditie of receiuing meates and drinkes directly from the hand, partly also because it was fit we should turne, not our eies onely but our mouth also toward them with whom we discourse.

Thirdly for the Nose, that the sauours of meates and drinks by which we iudge and discerne whither they be good or ill might more directly strike the sense of Smelling. Moreouer, the Eares were not placed in the backepatt of the head because there are no Nerues deriued thereunto; not in the top of the head least the couering of the Heade should hinder the ingresse of the sound. It remaineth therefore that it was most conuenient they should be placed in the sides of the head or the face iust against the region of the eies, and also be in man immooueable. In bruite beasts their scituation is somewhat otherwise, to wit, at the toppe of the Face, because their heades hang alwayes downeward vnto the earth to seeke theyr Foode. In Beastes also the eares are mooueable.

Apes Eares.

The Eares of Apes haue a middle position betwixt those of men and beastes, because it is a creature of a middle figure betwixt the erected frame of a man & the prone or bending posture of a beast. And as their position so likewise is their motion, not to bee immooueable as in Men, nor so mooueable as in other beasts but betwixt both.

Their Figure

The figure of the outward eare is round or semi-circular [Tab. 4. fig. 1.ᵇ. Tab. 5. fig. 6ᵇ. Ta. 6. fig. 7, 1] because that which is rounde is best secured from iniuries, as also most capacious. On the outside they are conuexe or gibbous. On the inside excauated like a denne

Table 4. Fig. 1. Sheweth the skin of the head together with the fat, and the glandules vnder the eares and the muſcles of the hinder part of the head and the eares.

Fig. 2. Sheweth the muſcles of the eares, of the eye-browes, and a few of the iawes.

TABVLA. IIII.

FIG. I.

FIG. II

A A. The skin of the head together with the rootes of the eares.

BB. The muſcle of the eare ſpringing from the *pericranium* or skull-kin.

C. The triangular muſcle mouing the skin of the nowle of the head.

D D D. Branches of the externall iugular veine.

E. The tip of the eare.

F. The circumference of the eare called *Helix* in Greeke.

G. The glandules of the eares, in which is the diſeaſe called *Parotis*.

The ſecond Figure.

A. The ſemicircular muſcle of the ear drawing the outward eare vpward, which was noted with B. in the firſt figure.

B C D E F G. The muſcle as it were diuided into 3. parts called *Tripartitus*.

H. The hinder part of the outward eare, into which the foreſaid muskle is faſtened.

I I I I. The circumference of the eare called the wing.

K. The lap or tip of the eare.

L. The little griſtle on the outſide of the hole of the hearing, which in ancient men is bearded, called *Tragus* becauſe it is like a Goates beard.

M M M. The skull as yet couered with the *Pericranium* or skul-kin.

N N N, The circumference of the temporall muſcle.

O, The muskle yet couered with the *Pericranium*.

P, The membrane, couering the ſaid muskle drawne aſide

Q Q Q. The fleſhy part of the temporall muskle.

R R, The iugular or yoke bone.

S S. A ſharpe proceſſe of the lower iaw.

V. The muskle *maſſeter* or grinding muskle, remoued here from the yoke bone whence it hath his originall, that the implantation of the temporall muskle into the proceſſe of the iaw might appeare.

X, The muskles making the Cheeks.

Y, Fleſhy Fibres going vnto the lips.

Z, A muskles of the lower lip.

a a, The muskle of the eye-brow.

b b, The vpper eye-lid hauing a muskle with tranſuerſe Fibers.

c, The eye brow hauing a circular muskle, wherby the external parts of the eye are exceeding conſtringed, as *Placentinus* ſaith.

den or cornered hole. Yet euen on the inſide there are certaine ſwellings anſwerable to the cauityes, to breake the violent ruſhing of the aire or wind or whatſoeuer ſhould vnawares be offered againſt them. For in theſe breaches of the eare as it were in hollow bodyes, not onely the ſound of the ayre that ruſheth in is readyly and exactly drawne and fully receiued: but alſo it is broken and boundeth or reboundeth as a ball againſt the ſides of the inequalityes till the refraction get into the circular cauity and ſo the ſound becomes more equall and harmoniacall. It attayneth alſo better vnto the Tympane or drum of the eare without trouble or moleſtation, and is imprinted vppon or into the inward ayre more ſtrongly and more diſtinctly; and beſide, by this meanes the ſound continueth longer as we may haue experience if we apply any hollow ſhell to our eares, for by that meanes the ayre is better gathered and more directly offered to the auditory nerue. The *Scythians* that liue in the cold Northernly countryes haue often their eares rotted off with cold, whereby their hearing is much impaired, to amend which default they faſten about the hole ſome hollow ſhell; imagine it be of a great Cockle or Scallop wherein the ayre is concluded, gathered and directed vnto the head.

The reaſon thereof.

How the Scythians make amends for the rotting of their eares.

The truth hereof may be diuerſly demonſtrated, firſt becauſe all ſounds are moſt exactly receiued in hollow and hard bodyes, as bels and ſuch like. Againe, thoſe men whoſe eares are cut away do receiue ſounds and articulated voices after an obtuſe, dul or confuſed maner like the fall of water or chirping of a Graſhopper, in ſomuch that the other eare which

is

is not vitiated is notwithstanding impaired, vnlesse that which is wounded be quite stopt vppe.

Adrian the Emperour.

Finally, such as are halfe deafe that they may heare the better, do set their hands to their eare with the palmes forward to gather in the sound, as we reade that *Adrian* the Emperor was wont to do. Another vse of this refraction of the aire is, least it should enter into the Eare too cold if it were not broken and beaten against the sides in the passage whereby it receiueth if not heate yet a mitigation of his coldnesse. And finally, if it were not for these breaches many violent sounds would suddenly rush into the eare to the great offence of the Hearing.

The magnitude of the Eares.

These Eares are not alwayes of one magnitude, But in some greater in some lesse, but most-what proportionable to the magnitude of the body, and yet it hath beene obserued that where there is greater store of vitall heate there the eares are some-what the larger. Howsoeuer, they are small in man in respect of other creatures, as well for ornament as because the head of a man (saith *Galen* in the twelfth chapter of his eleauenth Booke *De vsu partium*) was to bee couered eyther with a hat or a head-peece or some other couering; wherefore if mens Eares had bene as bigge as beasts it would haue beene very inconuenient, yet they are large enough to couer the passage.

Why they are two.

They are made double, not so much that when one is vitiated wee might haue vse of the other (although this bee a great commoditie) as for the necessity and perfection of the Sense.

The diuision of the outward Eare.

The whole Eare which *Vesalius* not vnfitly compareth to a fanne wherewith they dresse Corne, may fitly be diuided into an vpper and a lower part. The vpper which is hard & as it were stretched *Aristotle* in the eleuenth chapter of his first Booke *De historia Animalium* leaueth without a name, but *Gaza* his interpreter calleth it *pinna* [Tab.4.fig.1. Tab.5 bb] the Finne, as well because of the forme as also in respect of the vse: for the Forme, because that broad Gristle is not vnlike the Fin of a Fish: for the Vse, because as the fish guideth her selfe in the water with her Finnes, so these gristly partes cleauing to the sides of the head do guide the sound that it passe not away before it is communicated to the *Inward Aire*, and for the same cause it is called by some πτερύγωμα, that is, a *wing*; broade it is the better to entertaine or catch the sound which afterwarde descendeth by the inwarde compasse vnto the arched cauity that leadeth vnto the passage into the head.

The wing or fin of the eares

The lower part which is soft and depending [Tab.4.fig.1.[ll] Fig.2.[x] Table 5.fig.1.[a]] is called λοβὸς ἀπὸ τῦ λαμβάνειν, because we take hold of that when we wold admonish a man, and thence haply it was that the eare is consecrated to Memory. The Latines cal it *Fibra*. *Tully* in his second Booke *ad Quintum fratrem* cals it *Ansa Auriculæ* the handle of the ear, we call it the Lap of the eare, because it is a softe and flexible bodie, hauing in it neyther bone to stiffen it, nor gristle to harden it, nor Nerue to stretch it, and therefore it may bee perforated without paine or with very little, as we may see in young folkes of both Sexes, who vsually hang Iewels at it. *Laurentius* well obserued, that it is a signe of modestye or shamefastnesse, because vpon such a passion this part will grow redde. But the naturall vse of it is to conduct the excrements downward which yssue out of the eare.

The Lappe of the eare.

The outward circumference of the eare is called ἕλιξ *Capreolus* of the likenesse it hath to the writhen Tendrill of a Vine. [Tab.4.fig:1,[ff]. Table: 5,fig:1 bb] The inner compasse, which is as it were opposite to the vtter, is called ἀντέλιξ. *Pollux* calleth it *Scapha*, becaus it is somewhat like a Lighter or Barge. [Tab. 5.fig.1.[cc]] The great cauity which is compassed almost round by this inward circumference [Tab.5.fig.1] is called *Concha*, because it is like the shell of a Periwinkle and this is the principall part of the outwarde eare made so large that it might receiue all the sound which runnes within both Circumferences, but the cauity thereof groweth narrower toward the hole of hearing, that the sound being gathered into a narrower scantling might more suddainely and at once be offered vnto the Organ.

The seuerall partes of the outward Eare and their denominations.

But the Cauity which is next vnto the hole of Hearing wherein the eare-wax is, is cald κυψέλη *Aluearium*, and the bitter waxe it selfe *Aphrodisæus* calles κυψελίδα. That eminence which is opposite to the hollownesse [Tab.4.fig.2.[l]. Tab. 5. Figure 1,[c]] toward the temples which hangeth like a pent-house ouer the hole of the eare is called by *Ruffus* and *Pollux* τράγος *Hyrcus* the *He-geate*, because in this part there grow haires which in some men are so rigid and stiffe, that they are like a Goats beard.

The

Tab. 5. sheweth the eares and the diuers internal parts thereof.

Figure 1. sheweth the whole externall eare, with a part of the Temple bone.

Figure 2. sheweth the left bone of the Temple diuided in the middest by the instrument of hearing, whereabout on either side there are certaine passages heere particularly described.

Fig. 3 & 4. Sheweth the three little Bones.

Fig. 5. sheweth a portion of the bone of the temples which is seene where the hole of Hearing diuided through the middest, whereby the Nerues, Bones & Membrans may appeare as Vesalius conceyueth of them.

Fig. 6. sheweth the Vessels, Membranes, Bones & holes of the Organ of Hearing, as Platerus hath described the.

Fig. 7, and 8. sheweth the little bones of the hearing of a man and of a Calfe both ioyned and separated.

E. A branch of this nerue going through a darke hole vnto the Temples.

F. Another branch falling through the hole where by a veine doth enter in.

H, I. A round cauity in the fore-part whereof is placed, the bone noted with I. *Fig. 6.*

αα The fyrst hole of the Organ of hearing.

β The auditory Nerue diuided into two partes, where it passeth through the fourth hole. *γ* the iugular vein with a part of a nerue passing through the first cauity. *δ,* where it passeth through his second hole neere to *δ.* *ε* An artery entring that cauitie thorough the third hole, and a nerue falling through the same hole. H, the same artery falling through the fyst hole. *θ,* the lower part of the 5. nerue reaching vnto the 2 & 3. cauity. *θθ,* A higher part of the 5. nerue brought through the scruing canale or pipe vnto *i* where it falleth out. *κ,* the Tympane or Drum shutting the first cauity. *λ,* the three little bones of hearing ioyned together. *μ,* the third cauity or the Trumpet of the organ of hearing. V the second cauity or the mettall mine running out with three burroughs. *ξ, σ,* The Canale or watercourse carrying a Nerue and an artery, opening it selfe with two holes. *Figu: 7 & 8, ρ* The Hammer *φ,* the Anuile, *τ,* The Stirrop.

The part opposite hereto to which the lap grows somtimes is also haire, [Tab.5.fig.1.f.] & called ἀντίτραγος. The vse of both these is to forme the cauity and to hinder the sweat or any such like excrement or outward thing from falling into the eare. Betwixt these two there is a hollowed furrow like halfe a circle, which *Herophilus* calleth ξυστὴ and *Pollux* ἰχνιοχος into which the excrement or whatsoeuer issueth out of the eare falleth before it get into the large cauity and so fall away by the lap.

The vse of the outward eare.

The vse of the whole outward Eare which like a Fan is dilated, was especially to intercept the species of sounds wandering through the aire, and to gather them as it were into a bosome, or if you will, into a broade tunnell to be conuayed by manifold breaches or returnes to the hole of the Eare. Againe, the many oblique furrowes in the outward Eare doe breake the violence & force of the ayre, which otherwise might haply loosen or breake the fine membrane of the Tympane or drumme. There are also certaine bunching protuberations where the gristle swels vp into a prominence, which prominence, if the aire doe passe the hole of hearing, beats it backe againe forward toward the cauity. For because the holes of the Eares are placed in the sides of the head the sound may easily slip by them, especially when it commeth from behind vs and we moue forward, if it were not caught in these conuolutions and in the guttures of the gristly substance conueyed vnto the hole of hearing.

And hence it is that euen by instinct of nature we see brute beasts, as Dogs and Horses will pricke vp their eares, and partly turne them toward any sound or noyse that is made. And because the Eare might be thus prominent, as well in the parts as in the whole (for the whole eare standeth of a certaine distance from the head,) Nature hath made them of a cartelaginious or gristly substance, which out of doubt wold grow farther from the head if Nurses or carefull mothers who haue more respect of comlinesse then of vse, did not bind them downe in our infancy.

A fit similitude expressing how the sounds come through the aire vnto the eare.

If you aske me how the sound of any thing farre off can ariue vnto the eare; I will answer by a pregnant example on this manner: If a stone be throwne into the midst of a pond, it moueth the water in circles, one alwayes succeeding greater then another vntill the motion determine in the brinkes or bounds of the pond: so in like manner those bodyes which by their collision do make a sound, moue the ayre into orbes or circles succeeding one another, so that the circles which are neatest to the body from whence the sound came are but small, the rest which follow them grow greater and greater vntill they come vnto the eare, whereas when they beate they are latched in those furrowes wee spake of, and by them directed vnto the hole of hearing.

CHAP. XII. *Of the parts of the outward Eares.*

THis outward Eare is made of parts, some common, some proper: the common parts are the cuticle, the skin, the fleshy membrane, flesh it selfe and a little fat in the lobe or lap. The proper parts are muscles, veines, Arteries Nerues and a gristle.

The cuticle or skarfe-skin we haue spoken of before in the second book, as also of all the other cómon parts; only of the skin it selfe in this part we may say, that it is exceeding thin, yet somewhat thicker in the gibbous or backeside of the eare then it is in the concauous or foreside, and the nearer it comes to the hole of hearing, the thinner it is. This skin compasseth the eare round about, both without and within, and cleaueth very strongly and firmely to a little flesh and to the gristle, that the superficies of the eare, especially the inner might be smooth and slicke, not corrugated or vnequall, as well for beauty and comelinesse as also for the better reception of sounds: for *Aristotle* in the seuenth Probleme of the eleuenth section, enquiring why a house that is new plastered doth sound better then an old house? answereth, that the reason is, because the wals are smooth, which smoothnesse procedeth from density or fastnesse. It is reasonable therefore to thinke that the smoothnesse of the eare helpeth the sound, and therefore the very hole also of hearing is inuested with a thight, hard, thin and smooth skin, which cleaueth very closely to the mébrane there vnder. But where the skin incompasseth the lobe or lap of the eare, it is so exquisitely mixed with the membrane and the flesh that it cannot be separated from them; and therefore we may call that part a fleshy, fatty and spongy skin.

The skin of the outward eare.

Aristotle.

Why a new house sounds more then an old.

The veins of the eare.

The vessels of the eare are these. Veines of the eare *Hippocrates* tooke knowledge of, in his first booke *de natura hominis*. Branches they are dispersed on either side [Tab.4.fig.1.

Table 6. Figure 1. Sheweth the fore-face of the outward Eare without the skin.

DDD] from the externall Iugular as also from the lesser braunch of the internall Iugular veine which entreth into the Basis of the scull through the fourth hole of the Temporall-bones. There is a small branch also directed to the Organ of Hearing and into the first cauity [Tab. 3. lib. 7. fig. 13.ª] which bringeth bloud for the nourishment of the parts contayned, and haply also of the ingenite or in-bred ayre. And that there are veines deriued into this cauity, and vnto the membrane or drum, may be proued by the dissection of those bodies that die of an inflamatiõ of the brain or of the eares For if the hole of hearing be featly opned, you shall find small veines conspicuous in the mẽbrane or Tympane, which do not appeare when there is no inflamation, as wee said lately it hapneth in the white of the eye.

Arteries it hath from the inner branch of the *Carotis* or sleepy Artery which passe to the backeside of the Eare [Tab. 13. Lib. 6.°] that those parts and the in-bred ayre also might be refreshed with vitall bloud and spirits. The arteries of the eare.

Two small nerues it hath from the backeward, and two from the sides of the second coniugation of the marrow of the necke; and these are very small, sayeth *Galen* in the sixth Chapter of his 16. Booke *de vsu partium*, in Men and Apes, because their temporall muscles bee very small, and the substance of their eares is immouable: but in other creatures The nerues.

ſayth he whoſe temporall muſcles and eares are very large, theſe nerues alſo are large, becauſe of the ſtrength required to thoſe motions. The vſe of them in men is to bring Senſe to the eares and ſometimes to mooue the muſcles, for thoſe muſcles are not alwayes found.

CHAP. XIII. *Of the Muſcles of the outward Eare.*

MEns Eares are for the moſt part immouable, yet they may be moued, as appeareth as well by their muſcles as alſo by the nerues which, as we ſaid euen now, are founde in ſome bodies. But the muſcles are ſo ſmall and the nerues ſo threddy, that their motion is hardly perceiued: and Nature made them ſmall becauſe too much motion would haue vitiated the hearing, and therefore the head is rather made to moue ſpeedily on euery ſide toward the ſound or voice, which is not ſo in beaſtes whoſe eares are mouable.

Such as they are *Falopius* firſt found them out; and therefore the honour of their Inuention belongeth to him. They are of two ſortes, Common and Proper.

The firſt is Common to the Eare and both the Lippes, and is a portion of that muſcle which is accounted the firſt of thoſe which moue the cheeks and the skinne of the face, and is called *Quadratus*. [Tab. 7. fig. 1. L] The ſquare muſcle, it is inſerted with aſcending fibres into the roote of the eare [Table 6. fig. 1. Q.]

Table 7. Fig. 1. Sheweth the muſcles of the Forehead, the Eye-lids, and the Cheekes.
Figure 2. ſheweth the muſcles of the Noſe, Lips, the lower Iaw and of the bone Hyois.

FIG. I.

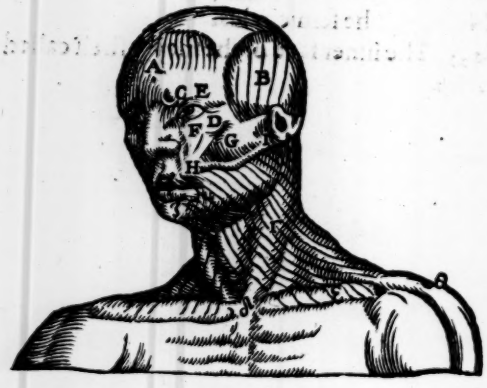

FIG. II.

A 1,2, The muſcle of the forehead and the right fibres thereof.
B 1,2, The temporall muſcle.
αβγ 2, His ſemicircular originall.
CE 1, the firſt muſcle of the Eye-lidde compaſſing the whole lid.
FD 1, the third muſcle of the wing of the noſe which endeth into the vpper lip.
GH 1, the muſcle of the vpper lip.
G 2, The place of the yoke bone without fleſh.
Γ 1, the broad Mouſe-muſcle ſtretched ouer the cheeks and all the lower parts.
δεζθ the circumſcription or circumference of this muſcle.
I 1, the yoke-bone.
I 2, The grinding muſcle or the ſecond muſcle of the Iaw.
The forward K in the ſecond figure ſheweth the higher griſtle of the noſe.
L 2, the wing of the noſe.
M 2, a muſcle forming the cheeks.
N 2, the muſcle of the lower lip.
O 2, A part of the firſt muſcle of the lower iaw called *Digaſtricus*, that is, double bellied.
P 2, the bone *hyois* is ſet in this place,
QR 2, The firſt muſcle of the bone *hyois* growing to the Rough artery,
S 2, the ſecond muſcle of the bone *hyois* vnder the chin
The lower T in the ſecond figure ſheweth the third muſcle of the bone *hyois* ſtreatched to the iaw. The vpper T in the ſecond figure ſheweth the inſertion of the ſeuenth muſcle of the head.
VV 2, two venters of the fourth muſcle of the bone *Hyois*,
The backward K (put in ſtead of *X*) ſheweth the ſeuenth muſcle of the head and his inſertion at the vpper T,
κλ 2, The originall of the grinding muſcle from the yoke-bone,
μ 2 the inſertion of this muſcle into the lower iaw,
ν 2 A ſmall nerue running to the forehead out of the orbe of the eyes, π 2, a nerue propagated to the face, ρσ 2, two beginnings of the ſeauenth muſcle of the head. T 2, His inſertion into the *Mammillary* proceſſe, υ 2, The clauicle or the coller-bone. φ 2, A place where the veſſels attayning to the head and the nerues of the arme do paſſe through.

The

The ſecond is a proper muſcle [Table 7. fig. 1. neare ª Table 4. fig. 1. ª ª figu. 2.ª] ſeated in the forepart vppon the temporall muſcle, and ariſeth from the vpper end of the muſcle of the forehead, and is inſerted into the vpper part of the eare.

The third [Table 7. fig. 1. neare O] ariſeth from the nowle aboue the *Mammillar* proceſſe, where the muſcles that moue the head and the ſhoulder-blade do end, and is implanted on the backſide of the eare.

The fourth proceedeth from the ſame *Mammillary* proceſſe vnder the ligament of the griſtle of the eare, and is inſerted into the whole roote of the eares griſtle. [Table 4 fig. 2.ª.] One part of it aboue, another part in the middeſt, and the third below. The more exact deſcription of theſe muſcles we referre vnto the booke of muſcles.

CHAP. XIIII. *Of the Griſtle of the Eare.*

THe ſubſtaunce of the outward Eare is neither bony nor fleſhy [the *interior* face of the Eare flayed is exhibited in the firſt Figure of the ſixt Table] but of a middle nature betwixt both, for if it had bene bony it muſt haue bene of a thinne bone or of a thick. If it had bene made of a thin bone, ſaith *Ariſtotle* in the ninth chapter of his ſecond booke.

Table 6. Figure 1. Sheweth the fore-face of the outward Eare without the skin.

Figure 2. ſheweth a ligament of the outward Eare whereby it is tyed to the Skull.

Figure 3. The ſtony proceſſe being broken ſheweth the firſt cauity and the holes thereof.

Figure 4. & 5. ſhew the Labyrinth, the Snayly ſhell called Cochlea, *two windowes and three ſemicircles.*

EEE, parts of the ſcull.

Fig. 3. 4. & 5.

F 3,4,5, the Ouall hole or the window of the labyrinth, in the 4. figure it is broken.
G 3,4, The window of the ſnayly ſhell or the winding hole.
H 3, The watercourſe or darke hole betwixt the *mammillary* proceſſe and appendix called *Styloides.*
I 3, The *Mammillary* proceſſe.
K 3, The cauity going vnto the *mammillary* proceſſe whoſe outward face is all ſpongy.
L 3. The *interior* face.
M 3, The knub of the nowle-bone inarticulated or ioyned to the firſt rack-bone of the necke.
V 3, The hole of the firſt payre of nerues of the internall *Iugular* veine. &c.
NNN 4,5, The ſemicircles.
O 4,5, The inner face of the ſnayly ſhell called *cochlea.*

Why not bony,

de partibus Animalium, then would it eafily haue bene broken. If it had beene made of a thicke and ſolide bone it would haue beene a burthen to the head, and beſide would not haue yeelded to outward occurrents. Againe, if it had beene as ſoft as fleſh it would haue fallen into it ſelfe and haue beene vtterly vnfit to haue made thoſe cauityes, protuberations, furrowes and ſuch like which in the eare are very neceſſary: neither would it haue receiued the ſound which muſt be returned from a hard body, and ſo the ingreſſe of the aire would haue bene hindered.

Why moderately ſoft.

It was made therefore of a ſubſtance moderately ſoft and moderately hard, that by reaſon of the ſoftneſſe it might be bent on euery ſide and giue way to the oppoſition of whatſoeuer doth light againſt it, that ſo it might neither be ſubiect to contuſion nor breaking. Againe, the moderate hardneſſe thereof makes it fitter to be ſtretched, to ſtand vpright, & to be alwayes open, that the ayre together with the ſound might euermore gather into it; for ſaith *Cicero* in his 2. booke *de natura Deorum*, when we are a ſleep we haue need of this ſenſe that we might be waked. Moreouer, the hardneſſe makes it fit to receiue the cauities and furrowes which are therein, and whereby the ſounds are retayned that they paſſe not the hole of hearing. Yea whileſt the ſound runneth through thoſe cauityes, *Ariſtotle* ſaith, it gathereth ſtrength, and by the refraction is after a ſort modulated or tuned and ſo commeth more welcome to the Tympane.

Cicero.

Why moderatelie hard

Finally, becauſe it is moderately hard it yeeldeth alſo a ſound and ſo the voyce or noyſe is better receiued, and as it were, formed without any eccho or ſinging, or other noiſe like the fall of waters which happeneth to thoſe *Scythians* of whom wee made mention euen now, who when their eares are rotted off doe apply hollow ſhels of Scallops or ſuch like behind the holes of their eares.

The originall of the cartilage.

Wherefore it conſiſteth of one griſtle [Tab.4.fig 1.] and that flexible, couered ouer with a thin skin which cleaueth cloſe vnto it. This griſtle proceedeth as it were out of the temples and ſtandeth a looſe from them more or leſſe. For the firſt originall of this gryſtle is from the orbe [Tab.3.lib.7.fig 9.y.] of the hole of hearing which is boared in the temple bone, and exaſperated or made rough in the circumference that the griſtle might better ariſe therfrom. At the very original it is thicker & harder; thicker that the root therof might be more firme; & harder becauſe of the neighbourhood of the temple bone from whence it proceedeth; and by how much it ſtandeth further of from the bone of the head by ſo much it becommeth the ſofter and the thinner.

The ligament

This griſtle is alſo tyed to the ſtony bone by a ſtrong ligament [Tab.8. fig.2 CCC.] which ariſieth with many propagations from the *Pericranium* where it tendeth toward the mammillary proceſſe. Theſe propagations when they haue attained to the eare, doe all ioyne into one ligament, which is inſerted into the vpper and gibbous part of the eare, to ſuſpend or hang the griſtle ſtreight vpward. This griſtle is oppoſed or ſet againſt the hole of hearing that the paſſage thereof might be larger and more extended into the hollowneſſe of the griſtle, by which meanes the ſound is as it were ſcouped vp.

CHAP. XV. *Of the inward Eare.*

The parts of the inward eare.

THe inward Eare hath many parts, fiue holes or paſſages, three ſmall dennes, ſmall bones as many; the Membrane or head of the drum called *Tympanum*; two Muſkles; a Nerue from the fourth and fifth coniugations: a veine & an Artery and the Inbred Ayre. All which are contayned in one bone called *Os petroſum*, or the ſtony bone, whoſe deſcription we will here proſecute at large, becauſe of the bones of hearing therein contained, and make but ſlender mention thereof in our booke of Bones.

The rockie or ſtony bone.

This ſtony bone ſo called, ſaith *Veſſalius*, becauſe it is like a rugged rocke, [Tab.3.lib. 7.fig.9.*ſ.e.*] is the third and interior proceſſe of the Temple bone running along obliquely forward from the hole of the eare, betwixt the Mammillary proceſſe and the proceſſe of the yoke bone, and buncheth out in the inner baſis of the skull, [Tab.9.fig.2. from a. Ftoward C. and beyond] betwixt the wedge bone aud the nowle bone, ſo that it is much more conſpicuous in the inſide of the skull then it is on the outſide. This proceſſe is ſomweat round, the better to containe a greater quantity of *Inbred aire*: long alſo ſomewhat like the ridge of a rocke, and that becauſe the nerue of hearing (which is the ſofteſt of all nerues except the Opticks) might run his long courſe from the braine without danger of breaking.

Wherefore

VVherefore the production of this bone is inward to receiue the nerue as ſoon as it yſſueth out of the *Cerebellum* or After-brane. Another reaſon why this production is lengthned, is becauſe it might make a fit channell or furrow wherein to carry a braunch of the *Iugular* veine or ſleepy artery to the braine.

But there where it yſſueth out of the Temple-bone it is broader and thicker, that thoſe turnings and cauities which were neceſſary for the Senſe of Hearing might be better inſculped or wrought therin; yet as it proceedeth forward it endeth by degrees into a ſharp Cone or point where the veine or artery entreth into the brain, and ſo the whole proceſſe is like a *Pyramis* or ſpire. [Tab. 9. fig. 3. o.

The names of it.

This bone is exceeding hard for the ſecurity of the Organ of Hearing, and harder indeed then any bone of the body, whereupon it is called λιθωδὲς *Petroſum* or *Lapidoſum*, the Rocky or Stony bone. Some vſe to cal the temple-bones *Lapidoſa*, & they call this bone *the interior proceſſe of the ſtony-bone*. In Infants it is called *Os labyrinthi*, the bone of the Labyrinth, in whome it is ſeparated from the temple bones (as alſo in a Calues head it will eaſily fall from them when it is ſodden) and wanteth the halfe of that paſſage, which maketh *the hole of Hearing* in growne bodies. For this hole in Infants is altogither griſtly and in diſſections found diſtinct from the rocky bone: and therefore becauſe it is without that paſſage we may in Infants perceiue without breaking the bone, the Timpane as wel the membrane or head of it, as alſo the bony circle to which the membrane is faſtned: but as the body increaſeth and the griſtly parts grow drie, they turne into bones euen the hole of hearing it ſelfe; and ſo the rocky bone groweth very faſt to the ſcaly part of the Temple bone vnder which it lieth, and becommeth as it were a proceſſe thereof.

How it is found in children.

The parts of it.

In deſcribing this bone, we muſt conſider his outſide and his inſide. His outſide as it appeareth either within the ſcull or without the ſcull. The outſide within the cauity of the ſcull is couered ouer with a hard & ſtrong cruſt, as hard as is the ſubſtance of the teeth. The ſuperficies thereof is ſmooth, not rough as it is without the ſcull but yet vnequall; becauſe in the middle of the length thereof it buncheth out by reaſon of the *bones of Hearing* which in that place are contained; [Table 9. figure 2. betwixt [n] and the lower [r]] ſo alſo in the vpper part there runneth a ſharpe and rough line through his length, whereby it is diuided into two ſides, and forward it endeth into a rough ſharpneſſe [Table 9. figure 2. from [r] toward [d].]

The outſide.

The perforations of the rocky bone.

It hath many perforations that the ayre hauing receiued as it were the ſtampe or impreſion of ſounds might paſſe through them vnto the inſtrument of Hearing. Theſe perforations are of two ſorts, ſome within the ſcull ſome without: within the ſcull there are two; one is a large and patent hole in the face of the proceſſe which looketh backeward, [Table 4. lib. 7. fig. 10. [a] Tab. 9. fig. 2. from [d] to [l]] and this hole reacheth obliquely outward almoſt to the very middeſt of the proceſſe: it is ſmooth and round in the ingreſſe, but dilated afterward by degrees as it were into two parts, whereinto the nerue of Hearing is implanted. This hole *Platerus* accounteth to be the ſixt of the Temple bones, and the fourth hole of Hearing. But we ſhall account it for the ſeauenth hole of the Temples.

Within the ſcul two.

The firſt.

This cauity in the bones of Children is ſhorter, and beareth the forme of a hollowed denne or of a porch. But in grown men when the bone is increaſed that forme periſheth and it receiueth the figure of a fiſtulated hole or winding burrough; preſently after the ingreſſe of which burrough (as may be perceiued in the ſcul without diſſection) may be foūd two holes in the bottome of the entrance which goe into two boſomes or pipes, the one vpward the other downward [Tab 9. fig. 2. [ef]] into which the nerue is deuided and through them conuayed. The one hole or pipe is higher and runneth more manifeſtly toward the vpper part of the hole of Hearing, paſsing obliquely outward to the inner part of the proceſſe and ſo into that canale or pipe which is called *Aquaductus* or the VVater-courſe. [ta. 8. fig. 3. [n]]

It is diſtinguiſhed or parted from the ſecond and third cauities onely by a thinne ſcale, and leadeth along the greater part of the nerue [Table 9. fig. 2. [e]] of which we ſhall ſpeake in the firſt cauity.

The other hole or pipe is lower and leſſer, ſometimes ſingle ſometimes double, appearing in the inſide of the paſſage, and leading a long ſmal ſurcles of the nerue into the ſecond and third cauities. [Tab. 9. fig. 2. [f]]

The ſecond,

The other hole of the Stony bone within the ſcull which *Platerus* calleth the ſeauenth hole of the Temples and the fift of Hearing, [Table 9. figu. 2. 7] is in the foreſide of the proceſſe

Tab. 10. *ſheweth the eares and the diuers internal parts thereof.*

H, the ſame artery falling through the fyſt hole. *ιι* the lower part of the 5. nerue reaching vnto the 2 & 3. cauity. *θθ,* A higher part of the 5. nerue broght through the ſcruing canale or pipe vnto s where it falleth out. *κ,* the Tympane or Drum ſhutting the firſt cauity. *λ,* the three little bones of hearing ioyned together. *μ,* the third cauity or the Trumpet of the organ of hearing. V the ſecond cauity or the mettall mine running out with three burroughs. *ξ, π,* The Canale or watercourſe carrying a Nerue and an artery, opening it ſelfe with two holes. *Figu:* 7 & 8, *ρ* The Hammer *σ,* the Anuile, *τ,* The Stirrop.

ceſſe, narrow and roug'h like a ragged cleft through which a ſmall artery paſſeth from the Organe of hearing vnto the ſcull: we will account this hole for the eight of the Temple bones.

The holes of the ſtony bone without the ſcull are three. The firſt (which we account for the firſt hole of the Temples runs into the hole of hearing, [Tab.3. lib.7.fig.9.7.Tab 9. fig.2.a.] which is called πόρος ἀκουστικὸς *meatus auditorius*. This hole, becauſe of the griſtle which is extended and ſtretched about the beginning thereof, hath a large and ample orifice reſembling a caue or den, and it runneth betwixt the mammillarye proceſſe, & a part of the Iugall or yoke bone. Without the ſcull. The hole of hearing.

In yong children, ſaith *Coiter*, it is all griſtly, in thoſe that are growne it is but halfe griſtly and halfe bony. The griſtly part groweth out of the griſtle of the eare: the bonie out the bony circle of the Temple bone. For in the firſt conformation it is like a bony ring diſtinguiſhed from the Temple bone by a cartilage comming betweene them, from which cartilage ariſeth the membrane of the Tympane or head of the drumme: and this may be perceiued in the skuls of infants new borne till they bee ſixe or ſeuen months old if they be boyled; but afterwards this griſtle is dryed vp & vtterly obliterated & the bony ring or circle, of which we ſhall ſpeake in the next chapter, is no more diſtinguiſhed from the hole of hearing but vnited to the reſt of the bone and ſtreigthned a little, making a long & round bony canal or pipe [Tab.9.fig.2.ll.] wherein to receiue a greater quantity of ayre, & alſo that the paſſage might more patent and open vnto any ſound: which canall runneth inward to the head of the drumme, [Tab.9.fig.2. from e to c.] and that obliquely vpward, or if you will deſcribe the progreſſe thereof from within foorth, then ſay, that it ſlopeth a little downeward, and from behind runneth ſomething obliquely forward into the outward eare, where it becommeth ſomewhat more ample and large.

This paſſage therefore is oblique and winding to breake the vehement appulſion, or ruſhing in of cold ayre, that it ſhould not diſſolue the harmony of the Tympane and nerue of hearing. Againe, that a ſtrong ſound before it affect the Tympane might be comunicated to the *internall ayre* to & the nerue; or be broken and ſo touch the membrane gently & without violence, for a ſlope blow offendeth leſſe then that which commeth in a ſtreight line, and yet for all this we ſee often times that the noyſe of great Ordinance or of Bels, if a man be in the ſteeple, yea an intollerable cold ayer doe affect the Eare with paine and dolour; ſomtimes alſo breake the Tympane from whence deafneſſe followeth. The forme of the hole of hearing.

This paſſage alſo runneth obliquely from behind forward and vpward, leſt thoſe things that fall outwardly vpon the eare ſhould eaſily be admitted into the cauity, as alſo if any thing haue by chance inſinuated it ſelfe that it might with greater facility fall forth againe. It is by degrees ſtreigthned or becommeth narrow; firſt that the ayer being beaten might be gathered into a narrow compaſſe, by which our hearing is farre more diſtinct. Againe, that if any ſmall creatures ſhould get into the entrance of the cauity, yet the ſtreightneſſe thereof in the bottome might ſtay their courſe or returne them backe againe.

The like alſo we may ſay of crummes, of peaſe, or of any ſuch thing that ſhould happen to fall into the eare. There is alſo in this place a bilious viſcide and bitter humor wherwith, ſaith *Cicero* in 2. booke *de natura Deorum*, as with lime ſuch creatures are intangled. Wherefore alſo there are haires growing in thoſe particles of the eare which before we called *Tragus* and *Antitragus* reſembling the beard of a Goate.

This hole alſo is ſolide and hard, for by that meanes the ſound in the paſſage beeing ſtronglyer beaten againſt the bony or hard ſides of the paſſage is ſo much the more intentended then if it had bene more membranous or ſoft. It is alſo inueſted or couered with skin, partly to breake the ſound which would haue bene more vehement if it had beaten againſt a naked bone: partly alſo leſt the bone ſhould haue bene corrupted or tainted by the ayer: wherefore it is hard, thicke, poliſhed and ſtrongly ioyned to the bone. The ſubſtance of it.

Finally, this paſſage in the beginning and the end hath certaine circles, the outward of which is rough, [Tab.9.fig.2.b.] becauſe of the griſtle of the eare which groweth therto: to the inner circle the ſmall membrane of the Tympane or the drumme-head is ſtretched and tyed. [Tab.9.fig.2.c.]

The primary vſe of this hole or paſſage is, that the ayer altered by the ſound, might through it be deriued vnto the eare, and ſo through the concauity thereof might inſinuate it ſelfe from the backepart obliquely forward to the membrane of the Tympane; for through narrow, concauous, ſmooth and hard paſſages ſounds, are commonly carryed, not onely The firſt vſe of it.

onely with more eaſe, but alſo do more exquiſitely repreſent the nature of the ſound. And this ſhall hee eaſily perceiue that will ſtrike a trunke very gently at one end, ſo that he that ſtandeth by him may not heare it; and yet if a man lay his eare to the back end of the trunke he ſhall eaſily heare how often the fore end is ſtriken; becauſe in the trunke as in a narrow place the ayre is condenſed and by that meanes the ſound vnited and ſharpned: whereas if the ayre that is beaten by the ſounding body ſhall paſſe thorough a large place, it will bee diffuſed and diſſipated and looſe much of his ſtrength.

The ſecond. The ſecondary vſe of this hole of hearing is for the expurgation of the chollericke excrement of the brain, (for phlegme is rarely purged this way becauſe of his thicknes) which through the veines attaineth to the membrane of the Tympane and thorough it ſweateth into the hole of Hearing. In this hole alſo we finde a muſcle of which we ſhall ſpeake afterward.

Another perforation. There is another hole which we account to be the third hole of the Temple-bone [Tab. 3. li. 7. fig. 9. V] ſcituated neare the firſt hole of the wedge-bone, and is a great deale narrower then the former. It is oblique, ſhort and double, and admitteth a braunch of the Iugular veine; emitteth alſo or ſendeth out a ſmall branch of the nerue of Hearing.

CHAP. XVI. *Of the Canale out of the Eare into the mouth.*

THe third outward hole of the Stony-bone which we account for the fift hole of the Temple-bone [Table 3. lib. 7. fig. 9. ſ] is ſcituated betwixt the *Mammillary* proceſſe and the appendixe called *Styloides*, and endeth into a hole or canale which paſſeth from the eare into the mouth. Of this paſſage *Ariſtotle* made mention, but *Euſtachius* was the firſt that deſcribed it, and after him *Voltherus Coiter*. This hole or paſſage is like a round pipe or ſmall quill, larger in the beginning and paſſeth obliquely to the inward and foreſide of the Baſis of the braine, and in the middeſt of foure holes it penetrateth the whole bone where it is encreaſed by a ſubſtaunce that is partly griſtly and partly membranous. But before wee proſecute this paſſage further, we will ſhew you thoſe foure holes in the middeſt of which this paſſage thorough the bone is.

Where it perforateth the bone.

The firſt therefore is on the backeſide where the ſleepy artery entreth into the ſcull. The ſecond is on the foreſide through which the fourth coniugation of nerues yſſueth out of the ſcull. The third at the outſide making way for the artery which is to be diſtributed into the *Dura meninx*. The fourth at the inſide is a fiſſure made of the extremities of the wedge and ſtony bones, paſsing obliquely downeward and forward. And in the very middeſt of theſe perforations doth this cauity pierce through the bone.

The ſubſtance of it. Now to return vnto the ſubſtance. VVe ſayd before that it was partly griſtly partly membranous. For at the laſt of the 4 holes or the fiſſure which is common to the wedge and the Teplebones the ſubſtance of it is griſtly and very thick. But on the oppoſite part it is not exactly griſtly but as it were membranous & becommeth thinner. This canale thus encreaſed with ſubſtance of another kinde paſſeth between two muſcles of the throate as the forenamed fiſſure paſſeth & neare the root of thoſe proceſſes which we likened to Bats wings, on the inſide, I ſay, of them it determineth into one of the cauities of the noſtrils, & is inſerted into the thicke coate of the Palat neare the roote of the *Vuula*. But the inward extremity or end of this paſſage where it reſpecteth the middle cauity of the noſtrilles becommeth a ſtrong griſtle bunching or ſwelling much outward, which is couered with the mucous or ſlimy coate of the noſe, and ſet as a Porter to keep the end or outlet of the paſſage.

The figure of it. The figure of it is not round but a little depreſſed making 2 angles, the hollownes thereof is much about the proportion of a gooſe quill, yet ſo that it is twice as broad in the ende as it is in the beginning, and is likewiſe couered with a mucous coate, but that thin.

Why griſtly. It was made griſtly that the way might be alwayes open and that it ſhould not hurt the neighbour parts with his hardneſſe, but eaſily yeeld without danger of breaking. Moreouer, it was couered with a mucous or ſlimy coate, which *Laurentius* compareth to a value ſuch as groweth within the veines as we ſhall vnderſtand hereafter: the vſe of which coate is to couer the orifice of this paſſage within the mouth, that euill vapours might not exhale out of the mouth into the eares. The termination of this paſſage is on both ſides common to the noſethrilles, the pallate and the canale it ſelfe, that by this meanes the mouth might be a fit receptacle for all the kindes of excrements of the braine; and (which ſheweth the wonderfull prouidence and wiſedome of Nature or rather of the God therof)

Where it determines in the mouth.

the

the very end of it is where the muscle of the Chops is scituate; that so when vpon our swallowing the chops are dilated or opened by the muscle, this passage also is recluded or opened to giue way to the descending excrement.

The chiefe vse therefore of this passage is for expurgation, to leade along the superfluities that fall from the heade, by the eare into the mouth, as also to purge and depurate that aire which is implanted in the instrument of hearing; for it was necessary that many excrements should in this place be gathered together, because the Braine lyeth aboue it which yeeldeth much excrement: and we may well conceiue that many of those Excrements are gathered together about the eare, by the quantity that issueth sometimes outward through the hole of hearing. The chiefe vse of it.

An honest man of good credit tolde me that hee had beene deafe three or foure yeares, at length his eare was cleansed by one that professed some skill in curing deafenesse, and that in two daies he drew out of his eare the quantitie of two great Wall-nut shels ful of wax, and that therupon he instantly recouered his hearing againe. If therfore there were so manie thinne excrements which could sweate through the fast membrane of the Tympane, what a multitude shall wee imagine may lurke within, which for their thicknesse cannot possibly sweate through? A Storie

Aquapendens also testifieth, that he hath often obserued these inward cauities especiallie in children to be full of a thicke humour, slimy and mucous, which ought to haue bene purged away by this canale or passage: otherwise if it stay within, either it altogether stoppeth vp the eare, or else being resolued by inward heat is conuerted into wind, from whence come those singing noises and murmurs of the eares and consequentlie the deprauation or vtter amission and losse of hearing.

Hence therefore we may obserue, that in inward offences of the eares, it is a very reasonable course for the Physitian to prescribe *Masticatories*, beecause the waies are open, either for nature to expell being prouoked, or for the medicine to draw euen crasse and thicke matter by this way into the mouth. Beside by this meanes the passage shalbe kept drie, and the drier it is the more fit to receiue sounds. And hence it is, that *Hippocrates* in the 17. Aphorisme of the third Section saith, that the North winde because it is drie makes a man heare the better, and on the contrarie, the South-winde which is moyst dulls and offends the eare. The vse of *Masticatories* in deafenesse.

Another vse of this Canale is for the behoose of the *In-bred aire* of the eare: first, to purge it and make it clearer, drier and thinner: againe to restore it and refresh it; for it is not to be doubted but that new aire is supplied out of the mouth by this passage. For considering that the *Ingenit ayre* is perpetuallie wasted by the inbred heate, it is agreeable to the wisedome of Nature that it shoulde bee supplied by a regeneration of newe aire which must be made of externall aire, because the ingenite aire was at the first made of externall. Furthermore, that the aire doth passe out of the mouth into the ears, we are taught both by *Aristotle* in the eleauenth chapter of the first booke of his Historie of Creatures and also by experience, because when a man yawneth wide hee cannot heare what is spoken, and beside he perceiueth a noise in his eares. In like manner, when a man blowes his nose or with anie force conteines his breath, hee shall euer perceiue that the aire entereth into his eares, and with a certaine perturbation whereby the implanted aire is disturbed, because it is a drift not without some violence or constraint; but vvhen the aire insinuateth it selfe of it owne accord for the refection of that which is bredde in the eare, then is the motion gentle so that we do not perceiue it. And beside the length of the passage prepareth and fitteth the newe aire for the refection and nourishment of the old. We may also imagine that by reason of this passage *Alcmæon* of whome *Aristotle* maketh mention in the place aboue quoted, did thinke that Goates drew their breath not onely by their mouths and by their Nosethrils, but also by their eares, which we haue no great Reason to thinke strange, because we see that cunning Tobacconistes (a generation of new and addle Artists) can driue the smoake out of their mouthes thorough their eare. The 2. vse of the Canale.

A third vse of this canale is, that if it happen the sound cannot directly passe vnto the Nerue of Hearing by the hole of the eare, that then at least some of it might this waie through the mouth be conueyed vnto the organ of Hearing, and so those that are deafe by outward accident might receyue the sound or voice by their mouths. And this wee may verie well discerne by the receipt of the sound of a Musicall instrument. For if a man The third vse

How a deafe man may bee made to hear.

stoppe

ſtoppe both his eares verie cloſe and hold a wand in his mouth, the other end whereof doth touch any inſtrument that is plaide vpon, he that ſo holdeth the wand in his mouth ſhall be able to diſcerne the Muſicke. In like manner if in the night time you be deſirous to know whether any man be comming toward you, ſet a ſtaffe vpon the ground or but a ſword, and hold the end or pommell betwixt your teeth, and you ſhall heare a great way further off then your outward eare will bee able to diſcerne eſpecially if the waie be ſtonie.

The fourth vſe.

A fourth vſe of this canale is, that in a vehement and violent noyſe ſuch as the ſhooting of ordenance, thunder & ſuch like is, the membrane of the Tympane or head of the drum might be ſecured from breaking, for ſurely it would be in great danger to breake if the *Inbred aire* had no paſſage out. For when this Inbred ayre is mooued if it could not retire backeward, it muſt preſſe the membrane outward toward the eare, and the outward ayre we know forceth it inward, by which two contrary inforcements it could not but be endangered, whereas now the inbred ayre hauing an out-let into which it may retyre, it leaueth the membrane ſcope and roome to yeeld to the impulſion of the outward ayre.

How this paſſage is found in a ſcull.

He that would find this paſſage muſt take a dryed skull and put a hogs briſtle into the hole of hearing, and he ſhall perceiue that it will iſſue out again in the palat of the mouth. But in a greene head the holes of this canale are very conſpicuous in the ſame palate. And thus much of the canale which runneth from the eare vnto the mouth, as alſo of the externall part of the ſtony bone within the skull with the proceſſe and holes that belong vnto it.

Of the ſuperficies of this bone without the ſcull.

The other part of the exterior ſuperficies of this ſtony proceſſe or rocky bone without the skul is diuerſly exaſperated and made vnequall with knubs, boſoms or cauities, poſroſities or ſmall holes and lines running in it. So that the ancients did rightly compare it to a craggy rocke. The vſe of which inequalities is that from them the muskles might better ariſe and into them be better inſerted.

The mammillary proceſſes of the ſtony bone.

This bone alſo hath belonging vnto it a proceſſe and an Appendix. The proceſſe is ſomewhat thicke, and becauſe it reſembleth the teats of a womans dug it is called μαστοειδὴς *mammillaris*. [Tab. 3. lib. 7. fig. 8. M. fig. 9. K.] This proceſſe is not found in infants, but ariſeth afterward. The appendix is ſlender, long and ſharpe, and therefore called ςυλοειδὴς. Some calleth it *Os ſagittale*, *os clauale*, *os acuale*; from the reſemblance it hath with an arrow, with a nayle, or with a needle. It is alſo called πλάικτρον, becauſe it is like a ſpurre. [Tab. 3. lib. 7. fig. 9. i i.] This appendix in infants new borne is griſtly, but afterward becommeth bony when the bones grow and the griſtles are dryed; yet for the moſt part as it is in other appendices there remaineth in it ſome remembrance of a griſtle. But of theſe we ſhall ſpeake more at large in our diſcourſe of the bones of the head. In the meane time thus much ſhall ſuffiſe to haue ſayd concerning the externall ſuperficies of this ſtony proceſſe of the Temple bones or of the rocky bone whether you will, as well within the skull as without.

Of the appendix Styloides.

The inſide of the ſtony bone. Three cauities.

On the inſide this ſtony bone is not ſolide, the reaſon was, that it ſhould not bee too heauy, but thrilled and perforated with infinite holes, dens and ſcrued paſſages, [Tab. 18. lib. 7. fig. 2. *a g*, 3. 2. *m n* E *i*.] and in a word, the greateſt part of it is a very ſponge wherein the implanted or inbred ayre is laboured or perfected. But in the middeſt of it there are three notable cauities formed, eſpecially to help our hearing; the ſmal partitions of which cauities, although they be very thin becauſe the bone ſhould be light, yet are they very faſt and ſtrong bones. But becauſe the membrane of the Tympane or head of the drumme is interpoſed betwixt the hole of hearing and the firſt of theſe cauities, we will intreat of the Tympane before we come vnto the cauitie.

CHAP. XVII. *Of the Membrane of the Tympane or head of the Drumme.*

The names of the mébrane of the Tympane.

THe Membrane of the Tympane which *Hippocrates* firſt of al men, in his book *de carnibus*, made mention of vnder the name of ὑμὴν τοῦ ἀκοῆς, that is, *of a skin in the hole of hearing*, is called by *Ariſtotle* in the 83. text of his ſecond booke *de anima* μήνιγξ. *Galen* in the ſixth chapter of his eight booke *de vſu partium*, calleth it σκέπασμα, *a lid*, and στέγασμα, *a couering*. Some call it *Tympanum*, becauſe it is ſtretched ouer the firſt cauity as a peece of Vellam ouer the head of a Drumme, or becauſe as a Drumme being beaten with a ſticke maketh a great ſound, ſo this membrane being beaten vppon by the ayre, communicateth this ſound vnto the

nerue

nerue of ſenſe. But it may moſt properly bee called not the Tympane or drumme, but the membrane or head of the drumme, becauſe it is ſtretched vpon the bony circle wee ſhall ſpeake of afterward, and receiuing the impreſsion of the ſound returneth the ſame againe vnto the ſenſe. [Tab. 10. fig 3. and 4. p. Tab. 11. d.] It is ſcituated betwixt the hole of hearing, at whoſe inward end it is ſet, and the firſt cauity of the inſide of the ſtony bone, which cauity we properly call *Tympanum*. It is extended ouer the cauity obliquely forward and vpward, as if a man ſhould couer the ſloping cut of a writing pen with a filme: and the reaſon of this ſcituation is, becauſe it might more directly reſpect the firſt cauity which is ſomewhat higher then the hole of hearing. Againe, that the violence of the ayre, of water or of any ſuch like that might by accident fall into the eare, ſhould not directly or by a right line attaine vnto the membrane to offer it violence.

Situation.

The reaſon thereof.

The ſecond reaſon.

The figure of it is round [Tab. 10. fig. 6. x x. Tab. 11. d.] curued a little inward in the midſt like that herbe which we call *Pennigraſſe* or *Venus nauell*, the better to receiue the ſound which commeth from without, becauſe that which is concauous or hollow doth more perfectly, and fully receiue the ſound.

The figure of it.

Concerning the ſubſtance and originall of this membrane, there are almoſt as many opinions as there be writers. Some think it ariſeth from the Brain, ſome frō the *dura meninx*, ſome from the *perioſtium*, ſome from the *pericranium*, ſome from the nerues of the firſt conjugation, ſome from the *pia mater*. But if it may bee lawfull for vs to interpoſe our opinion, we perſwade our ſelues, ſaith *Bauhine*, that it ariſeth from the ſeede it ſelfe, as beeing generated in the firſt conformation as we ſayd before the membrane of the Criſtalline humour was generated; and the reaſon that perſwadeth vs thereto, is, becauſe the very ſubſtance of it differs from the ſubſtance of the other membranes in the body. But if this opinion ſhould not pleaſe, we next of all incline to them who produce it from the *perioſtium* becauſe if you diſſect the head of an infant, you ſhall finde this membrane to cleaue to the *perioſtium*, [Tab. 11. k k.] where it couereth the ſcaly bone and the neighbour parts: as alſo that at the hole of hearing the *perioſtium* is dilated, where there breaketh or riſeth out of the ſtony bone a little oblique and round proceſſe much like a quill, when the firſt oblique inciſion is made in it toward the framing of a pen, which proceſſe was ordayned that this membrane might be connected with the ſtony bone.

Diuers opinions concerning his originall.

This proceſſe is called the ring or the bony circle [Tab. 10. fig. 3. *. Tab. 11. e.] out of whoſe circumference the hole of hearing beginneth. This proceſſe hath a double originall [Tab. 11. n.] the lower groweth out of the ſcaly bone and reſembleth a knub or knot, which bending a little obliquely inward is placed before the doore or entrance of the firſt cauity, where on the inſide it hath a round furrow, or is lightly excauated in the middeſt round about the circumference with two bony brims or edges ſwelling out on either ſide, in which furrow the membrane groweth very faſt round about, that it might bee ſecured frō the violent motions either of the external Ayre entring in, or the internal ayre beating outward, as it happeneth in oſcitations or yawnings when wee hold our breath long, or when we blow our Noſes.

The bony ring.

Wherefore it is moſt like that circle in a Drumme to which the Vellam is faſtened. [Tab. 10. fig. 3. & 4. q. Tab. 11. d.] And this bony ring in infants is eaſily ſeparated from the Temple bone, but in growne bodyes it is ſo cloſe ioyned on one ſide to the ſtony bone on the other ſide to the hole of hearing, that a man would not thinke it had beene euer ſeparated from them: neither indeed can it bee ſeparated in growne bodyes without breaking. Yet the furrow remaineth ſtill to be ſeene. And thus the membrane of the Tympane ſeemeth to be ſeparated in the circumference from the *Pericranium*. But let vs heare what *Galen* can ſay of this membrane.

Galen inquiring into the ſubſtance of this membrane, and inſtituting a compariſon betwixt the couering or coate of the Opticke and the firſt nerue of hearing, and afterward of the inſtrument of ſmelling, ſheweth; *That it was not fit theſe Nerues ſhould be left naked, becauſe then they would haue bene expoſed to all outward iniuries. Seeing then they needed a couering, either it muſt be craſſe and thight as that of the eye; or rare & porous, or in a meane betwixt both. It behooued not it ſhould bee craſſe and thight, becauſe ſuch a couering would haue hindered the acceſſe of the Ayre when it was mooued, eſpecially if the motion were but eaſie, as it is when we ſpeake ordinarily one to another. Neither ought it to haue beene rare and porous, for then the Ayre would haue peirced through it and ſo the nerues ſhould eaſily haue bene offended and the Braine it ſelfe refrigerated.*

A paſſage out of *Galen* proouing that hee knew this membrane.

H. the ſame artery falling through the fiſt hole. *ι,* the lower part of the 5. nerue reaching vnto the 2 & 3. cauity. *θθ,* A higher part of the 5. nerue broght through the ſcruing canale or pipe vnto *s* where it falleth out. *κ,* the Tympane or Drum ſhutting the firſt cauity. *λ,* the three little bones of hearing ioyned together. *μ,* the third cauity or the Trumpet of the organ of hearing. V the ſecond cauity or the mettall mine running out with three burroughs. *ξ, π,* The Canale or watercourſe carrying a Nerue and an artery, opening it ſelfe with two holes. *Figu:* 7 & 8. *ſ* The Hammer *σ,* the Anuile, *τ,* The Stirrop.

Wherefore Nature framed a Muniment or defence, to helpe the ſecurity of the Inſtrument, of moderate Conſiſtence. And thus hee concludeth: *Nature therefore foreſeeing that if ſhee had made the conſtruction of that Nerue with a ſtrong Muniment, it would indeede haue beene fitte to beare off offences: but the Inſtrument of the Senſe muſt of neceſsity haue beene Deafe. Againe, if the conſtruction of the Nerue had had no defence, it would haue beene very ſubiect to outward iniuries: and therefore ſhee tooke a way betwixt them both, and made for the conſtruction of this Nerue a helpe, neither too ſtiffe to hinder the Senſe of Hearing: nor too rare, that the ayre ſhould penetrate through it, but of a moderate Conſiſtence, which might not onely ſecure the Inſtrument from violence, but alſo receiue and returne the impreſsions of ſounds.*

Againe, the ſame *Galen* writing of the couering *of the Inſtrument of Smelling*, ſayeth, *that it needed σκεπασμα a Defence more rare then that of the Inſtrument of Hearing which is faſt and thight, becauſe the obiect of the Senſe of Smelling is thicker then the obiect of the Senſe of Hearing: for the obiect of Smelling is a vaporous ſubſtance wherein the odour doeth exhale, but the obiect of Hearing is ayre altered only by an impreſsion of Sounds.*

By this wee may ſee that *Galen* was not vtterly ignorant of this membrane, and wee haue the rather inſerted this paſſage out of him, becauſe many late Anatomiſtes haue auouched that *Galen* made no mention thereof at all, but was vtterly ignorant of it. VVe returne now vnto the membrane.

The ſubſtance therefore of this membrane is thinne, faſt, dry, tranſlucide and of exquiſite ſence: ſo thinne and fine that *Hipocrates* compares it to a Spiders webbe, the better to tranſmit an eaſie voice or ſoft ſound (for it was neceſſary vnto the act of Hearing, or if you wil vnto the paſsion of Hearing, that the ſound ſhould be communicated with the In bred Ayre although the ſubſtances of the outward and inward ayres are not mingled) and yet ſo ſtrong withall that it might be able to beare a pulſation which might affect the inſtrument of Hearing. The ſubſtãce of the membrane.

Wherefore Bony it behoued not to be, for then the inſtrument of Senſe would haue beene deafe, becauſe the in bred Ayre would not haue receiued the Sound and alteration of the externall ayre; and if the bone had beene ſo thin that it could haue tranſmitted the affection of the ayre, then alſo would it haue bin in danger of breaking. Why not bonie.

It was not fit this couering or inſtrument ſhould be fleſhy, becauſe if that which receiued the ſound had beene laxe or looſe it would not ſo well haue tranſmitted the impreſsion, for wee ſee that the ſtrayter a drumme is braced the ſhriller ſound it yeelds. Againe, if it had beene fleſhy it would haue bin ſoft and full of moyſture, and by that meanes would haue admitted of many things to cleaue or ſticke vnto it which now doe fall away from it, becauſe it is membranous. Why not fleſhie.

This partition therefore or muniment, or couering, call it what you will, is membranous and thinne withall: for if in the firſt conformation it bee produced a thicke and faſt membrane then is the party deafe incurably, as *Arantius* and *Laurentius* haue well remembred.

But wee finde ſometimes before this membrane on the outſide that there groweth a certaine thicke coate beſide the intent of Nature, of which *Aegineta* maketh mention in the 23. Chapter of his 2. booke, and *Aquapendens* ſaith he found it twice, but *Aegineta* teacheth alſo the way how to cure it; yet it is much to be doubted that if it grow from the Natiuity ſuch children will become deafe and dumbe; Deafe becauſe this coate hindreth the appulſion of the ſound vnto the membrane; Dumbe becauſe they are not able either to conceiue with their minds or to vtter with their voices, that they are altogither ignorãt of. How children become deafe and dumbe.

And as ſuch a coate or filme before the membrane doth cauſe deafneſſe, ſo it ſometime hapneth that immediatly behinde the membrane there is a collection of mucous matter, or an affluence of ſome humour from whence proceedeth a great difficulty of Hearing hard to be cured: but if the humour be thinne then the Hearing is not ſo much impeached as the patient is vexed with ringings, ſingings, whiſtlings and hiſsing murmures in his Eares. Furthermore this membrane is thight and faſt, hauing in it no conſpicuous pores but neruous & ſtrong, the better to reſiſt outward iniuries & violent incuſions of the ayre.

It is alſo very dry that it might more readily receiue the Sound, and more diſtinctly make repreſetation of the ſame. For we imagine that the image of the Sound is receiued in this membrane without the matter, euen as the images of colours are receiued in the horny membrane of the eye. Beſide *Hippocrates* ſayth that dryneſſe is a great helpe to the conception or reception of Sounds, becauſe that which ſoundeth ſhrilleſt is fartheſt hard, Why the mẽbrane is dry.

as we haue experience in ſmall bells which are made of thin and faſt Lattin plate.

This membrane is alſo tranſlucide and polliſhed like a Looking-glaſſe both within & without, ſauing that on the inſide the proceſſe of the bone cald the Mallet or Hāmer is extended vpward vnto the middeſt thereof, like as we ſee in the tayle of a drumme there is a chord ſtretched ouerthwart through the midſt.

The diuers vſes of the membrane.

The vſe of this membrane is to cloſe vp the hole of Hearing in a round compaſſe, & like a hedge or wall to diſtinguiſh it from the fourth cauity of the Stony-bone, and therefore *Laurentius* calleth it *ſeptum*, the partition. It ſerueth alſo to diſtinguiſh the externall from the internall parts of the eare; but eſpecially to ſeparate the In-bred ayre, whoſe duty it is to receiue the impreſsions of Sounds from the externall or the ayre that cometh from without, for if theſe two ayres had beene mixed and confounded, the outward ayre being oftentimes foggy and thicke, muſt needes haue made the inward ayre alſo more vnfit for ſenſation. Neither doeth it only keep the inward ayre from permixtion with the outward but alſo containeth it that it ſhould not vaniſh of it owne accord, or be diſperſed and diſſipated in vehement noyſes or ſounds. Adde hereto that it keepeth out the externall aire ſo that neither the cold nor heate thereof can offend the nerues of the braine. Finally it defendeth the inward parts from outward wrongs, ſo that if a man be ouer head and eares in the water, yet the water cannot paſſe beyond the Membrane: In like maner it keepeth out flies and other ſuch buſie creatures, duſt and whatſoeuer elſe ſhould happen to fall into the hole of hearing.

But becauſe the thinneſſe of this membrane made it ſubiect to bee violated or indangered by ſuch outward accidents, Nature for more ſecurity hath placed on the inſide thereof three bones, a chord or ſtring and two muſcles wherby this membrane is made better able to endure the force of the ayre when it is beaten againſt it.

CHAP. XVIII. *Of the ſmall bones of the Organe of hearing, and of the Chord.*

The finders out of theſe bones.

The three bones of the Organe of hearing were not knowne to Anatomiſts till the age wherein we liue. Thoſe two which are knowne by the names of the Anuill or the Stithy, and the Mallet or Hammer were inuented or found out by that reſtorer of Anatomie, *Iohannes Carpus* of *Bononia*, and the third *Iohannes Phillippus Ingraſſias* challengeth vnto himſelfe, ſo doth alſo *Columbus* and *Euſtachius*, and well it may be that all theſe being ſo oculate Anatomiſts did find it out by their induſtry. But now we haue them, it ſhall bee more expedient preciſely to deſcribe them vnto you then to determine who were the firſt inuenters of them.

The ſcituatiō

Theſe bones therefore are ſcituated in the firſt cauity of the ſtony bone, which before we called the Tympane that is the drume or Taber, and becauſe their figure is diuers they haue alſo diuers names giuen them, partly from the ſimilitude they haue with the things, whoſe names they beare, partly alſo from their vſe. The firſt is called *Malleus* or *Malleolus* the Mallet or the Hammer. The ſecond *Incus* the Anuill or the Stithy. The third *Stapes* the Stirrop [Tab. 10. fig. 6. 7. 8.]

Their nerues.

The Mallet.

The Hammer or Mallet [Tab. 10. fig. 4. r. fig. 5. C. fig. 8. q. Tab. 11. c. l.] is ſeated in the beginning of the firſt cauitie of the ſtony bone [Tab. 10. fig. 2. neere to c.] at the end of the hole of hearing. This bone ſaith *Coiter* hath his name rather from his vſe then from his forme, becauſe when the membrane is mooued, the Mallet alſo is mooued therewithall: or becauſe like a hammer it lies vpon the Anuill, and in the motion beates vpon the membrane. Others doe liken it to the thigh-bone, as *Veſſalius* on this manner. As the thigh neere the necke thereof hath two proceſſes, ſo this ſmall bone hath two proportionable proceſſes in the necke thereof, whereby it groweth more ſtrongly to his membrane. Againe as the necke of the thigh bending obliquely to the cauity of the hanch endeth in a round head; ſo this bone departing inward from the membrane and ending in a round ſmooth & plain head, is ioyned to the vpper part of the other bone by the interpoſition of the membrane, as if a hammer were looſely tyed to a Smiths Anuill. This firſt bone therefore is long and crooked, hauing a head, a necke, and a taile.

His head.

The head is the vpper and thicker part, long and bunching out, for this head is not perfectly round, as hauing ingrauen in the out ſide of the top a ſmal and long cauity wherin it receiueth the head of the ſecond bone which we called the Anuill, whereto being ioyned, it lifteth it vpward and forward to the ſide of the hole of hearing.

Necke.

The necke of it is but narrow, yet on the backeſide thereof do two ſmall proceſſes

ſhoote

ſhoote out, which are very ſlender and ſharpe. To the vppermoſt adhereth the ligament or chord & the lowermoſt reſteth vpon the membrane that it might not be driuen too far inward or broken. But the vſe of this proceſſe I cannot better demonſtrate then by thoſe Chords which they vſe to ſtretch vpon the bottome of a drumme whereby it is ſecured from the violence of the aire which is within it; which aire otherwiſe being ſo violentlie and ſo often beaten, would rend the bottome aſunder. Betwixt theſe is a ſmall cauity & right oppoſite againſt it a little knubbe into which one of the Tendons of the Muſcle is implanted, as the other is into the necke.

The taile of this bone which *Fallopius* calleth *Pediculus* as it were the *Stalke* is ſomwhat broad in the top, but endeth into a ſmall knot which receyueth the inſertion or tendon of the the Muſcle; (*Columbus* addeth, that into this ſharpe proceſſe there determineth a ſmall Nerue from the fift coniugation which affoordeth a hairy and crooked braunch which is inſerted into the labyrinth of the eare) preſently after it runneth backward and downward, and by degrees endeth into a ſlender and ſharpe proceſſe, ſomwhat rough and a little incurued or hooked, ſo that it cleaueth to the Membrane of the Tympane, not in the end or point of this proceſſe but thoroughout his length, yet not in the verie middeſt of the Membranes bredth. [Tab. 10. fig. 4. from [r] to [r]] And Taile.

The reaſon of this Connexion is partly to defend the Membrane from outward violence, that it ſhould not be driuen beyonde his extent (wherein alſo it is aſsiſted by the Chord of which we ſhall heare euen now) partly to draw it downward and inwarde for the proceſſe we ſpake of is curued or hooked inward, and by this meanes the Membrane is made inward conuexe, and outward hollowe, in which figure it is alſo by this proceſſe preſerued, whence it commeth to paſſe that the outward aire which entereth into hole of Hearing ſlideth from the ſides of the Membrane and gathereth it ſelfe togither in the center where the Mallet hangeth, and beeing ſo vnited and intended is a great furtherance for the communication of the ſound to the inward partes.

Againe, as this hammer groweth to the Membrane [Tab. 10. fig. 6 [n]] by his lower proceſſe and the inferiour part of his taile, as alſo to the orbe of the hole of Hearing by the benefite of a Ligament which runneth ouerthwart from the prominence which is on one ſide the hole to the prominence on the other; ſo that it is no where at libertie, but on euery ſide faſtned to the Membrane: in like maner the head therof is articulated to the Anuill vpon which it lyeth by that kinde of articulation or iuncture which we cal *Ginglymos*. [Tab. 10. fig. 6, 7, 8] For in the Hammer and the Anuile there is a cauity and a head, and the Hammer is moued aboue the Anuile. Notwithſtanding this Hammer & the Anuile after a man is dead are ſo cloſely ioyned (whither it be ſo in liuing bodies it is much doubted) that Nature ſeemeth to haue as much vſe of their continuity & vnity as of their diuiſion and plurality: for being two they do better ſafegard and defend the Membrane, but their continuation auayleth no whit leſſe for the better conueyance of the ſound. Wherefore although the articulation of theſe two bones is worthily ſaide to be *per Ginglymon* becauſe they mutually receiue and are receiued one of another, yet becauſe of their ſtraite and cloſe copulation ſome are of opinion that their iuncture is rather to bee referred to that kinde which wee call *Synarthroſis*, the meaning of which words of Art ſhall be at full expounded in our laſt booke of the bones. The Cõnexion of the Hamer.

Finally, the Hammer is a longer bone then the Anuile but withall more ſlender, becauſe it was to mooue aboue the Anuile, and wee know it is reaſonable that that vvhich beareth ſhould be greater then that which is borne. Notwithſtanding both theſe bones in the place where they are articulated or ioyned, are much greater and thicker then in their other part, which thing to ſay true may bee obſerued almoſt in the articulations of all other bones of the body. The forme of it.

The Anuile [Tab. 10. fig. 4 [f]. Fig. 5. I. figure. 7 and 8. [b]. Tab. 11, [m]] is the ſecond bone which is ſituated in the hinder ſide of the firſt cauity and lyeth nexte to the Hammer to which it is oppoſite and couereth (ſaith *Coiter*) that part of the Membrane which is not couered by the Hammer, yet ſo that his thicker part is toward the eare and his loggos (if we may ſo cal them) or his thinner parts toward the Tympane. Some are of opinion as *Columbus* and *Archang.* that this bone had his name from his action, becauſe as an Anuile it receiueth the ſtroke of the Hammer which mooueth aboue it and beateth againſt it. Others conceiue that it hath the name from the ſimilitude it hath with a Smiths Stithy or Anuile, not that great one wheron they driue ſledges of iron, but the little and moo- The Anuile. The reaſon of the name.

ble Anuiles which are partly plaine and partly round. And hereupon *Vesalius*, *Eustachius*, *Coiter*, *Platerus* and *Aquapendens*, because it is not altogether plaine as a great Anuile is, but hath an vnequall cauity such as is to be seene in the top of the *Grinding* teeth, haue likened it to a tooth hauing two fangs or rootes, the one longer and smaller, the other thicker but shorter, insomuch as they call it not *Incus* or the *Anvile*, but *Dens* or the *Tooth*.

Why called *Dens*.

The forme of it.

This bone is shorter and thicker then the Hammer (*Aquapendens* saith as thick againe) & hath two legges; for in the vpper extreamity it is thicker and swelling, and in a smooth cauity receiueth the head of the Hammer: it hath engrauen in it a small *sinus* or boson, which *Aquap.* calleth an *vnequall cauity*, in the midst whereof riseth a Line, as it is in the bone of the *Cubite* where it is articulated to the Arme, so that the articulation thereof is more truely sayde to bee made by *Ginglymos*, which for the motion is more expedite and ready. And as the head of this Anuile is articulated with the Hammer, so the productions or processes thereof doe grow to the orbe of the hole of Hearing, and to the toppe of the Stirrup or third bone. For the lower end thereof which is also the smaller, doth deuide it selfe into two slender and acute processes (which *Fallopius* and *Laurentius* with some others doe call Legges) standing off one from another.

The articulation.

The processes.

The higher of these which is the shorter and the thicker, is somewhat broad, a little intorted or bent inward and leaneth vpon the Scaly bone of the Temples, & by a transuerse ligament cleaueth to the walles or sides of the orbe of the Tympane euen there where the Watercourse slideth, & by this meanes it is tyed more strongly to the Hammer, that when the membrane hapneth to bee vehemently shaken, the two bones might not be separated one from the other.

The other processe of this Anuill or roote of this Tooth is somewhat longer, slenderer and bending downward; yet sensibly intorted vpward it appeareth aboue the membrane and is tyed to the top of the stirrup by the mediation of a ligament and affixed thereto by that kinde of coniunction which we call *Arthrodia*, occupying that place of the membrane wherein the Hammer is not, whereby it might *Perceiue* or receiue the pulsion of that part, and communicate the Sound to the stirrop, from whence through small holes it is ledden long vnto the nerue of Hearing.

The stirrop.

The Inuéters

The Stirrop [Table 10. fig. 4.[e] [f] fig. 8.[r] Table 11.[f]] called *Stapes*, is the third bone of the Eare, which the first Inuenters did very aptly expresse by this resemblance. Many contend about the Inuétion of this bone; among the rest *Columbus*, *Ingrassias*, *Fallopius* & *Eustachius*, all excellent Anatomists and haply all of them as fortunate in the finding it out as they haue been diligent to search into the secret corners of man; and therefore we wil not determine any thing in the preiudice of any of them. VVe finde it to be scituated as it were in the middest of the first cauity of the stony bone neare the *Ouall window*.

The figure.

In bruite beastes it is triangular, very like the greeke letter Δ [Table 10. figur. 8. sheweth the figure of it in bruite beastes] but in men it may bee sayde to bee formed of two parts, [Table 10. fig. 7. sheweth the forme of it in men] the one *superior* which is bent like a bowe hauing two smal legges somewhat sinuated, which becomming narrow are inserted into a transuerse Basis.

The top.

The top thereof is not sharpe but hath a smal plaine and round head, wherewith like an Arch it sustaineth the longer processe of the Anuill, or if you will the Stirrop hangeth to this processe by the mediation of a ligament.

The sides.

The sides or Legges of this Stirrop are very small and depart but a little asunder, making a hole betwixt them more long then round. Some say it is Triangular, others of an Ouall forme; but the Basis of the bone which is the part remaining is transuerse, somewhat broad and the edge thereof a little thicker then the other part.

The Basis.

The Basis also shooteth out a little beyond the legges or side-bones thereof, whereby it is articulated to the bone at the *Ouall window*, and is firmly fastned to the membrane which shutteth the perforation, and that by the helpe of a Ligament arising from that side of the head which hath the cauity. *Varolius* called it very elegantly κανονίδιον as it were the *Pupilla* of the Hearing. And on this manner it doeth exactly represent the forme of a Stirrope, not such a stirrop as is vsed now a dayes, but such as wee see grauen and figured in old pictures and tables, that is, triangular, and representing the fashion of the greeke letter Δ.

The perforation.

Why lesse then the rest.

This bone is much lesse then either of the other two, for if it had been bigger or waighed more, then being mooued together with the other two, it would haue drawn the membran

brane downeward. In the middest it is perforated or open like a stirrop, that it might be the lighter, and that hereunto the Inbred ayre might insinuate it selfe and be mooued. Againe the better to coūtray the sound which it receiueth communicated from the Anuill not only to the depth of the first cauity, but also beyond to the other cauity, & so through the *Ouill window* directly vnto the Labyrinth. Wherefore without this stirrop the sound could not haue beene transported into the whole cauity.

Why perforated in the middest.

For example, as the visible species or forme which is receiued within the horny coate must first passe through the marrow and streight hole of the *Pupilla* or Apple of the eye before it can ariue at the Cristalline humour: so the species or forme of the sound which hath gotten into the concauity of the membrane, must passe vnto the chiefe Organe of hearing through the small hole of the stirrop bone: and thence it was that *Varolius*, as wee said euen now, called this hole of the stirrop *Pupillam auditus the Apple of the eare*.

Varolius.

Wherefore, as wee sayd, the formes of sounds passe through the emptie hole of the stirroppe into the cauities which are wrought by nature in the stony bone where they meete with the Inbred Ayre, which may also be compared to the Cristalline humor. For as the Cristalline is the chiefe instrument of the sight in respect of reception of Images or Formes; so is this In-bred aire of the Eare the chiefe instrument which receiueth the formes of sounds, although there bee another more noble Organ which iudgeth of them.

Moreouer, least these three bones if they should haue mooued inconstantly, might haue indangered the membrane to which they are firmly tyed by drawing it too much this way or that way, it is fastened to the bone with a small ligament or chord, reaching ouerthwart from the sides vnto the top of the stirrop. Yea they are tyed together with slender and soft membranes which do the office of a ligament, and that by two ioynts which in their extremities are crusted ouer with a gristly substance after the same manner that it is in other bones, and so their articulation doth not differ from the Syntax or coniunction of other parts.

The reason of their connexion.

They were made three in number (though some creatures haue but two as *Placentinus* recordeth) for their better motion whereby the membrane is secured, which otherwise in violent concussions of the ayre might haue beene broken. For if it had bene but one bone, the membrane in impulsion could not haue giuen place because the bone would not haue bent therewith; or if the processe of the bone should haue yeelded, being necessarily so fine and thin, it might easily haue crackt a sunder. Wherefore the membrane of the Tympane is so fastened to the tayle of the Hammer that it might not breake when it is violently driuen inward: And againe the taile or handle of the Hammer cleaueth vnto the membrane that it might not be driuen too much outward. But that it might better resist any violent motion outward or inward there were two other bones added to the Hammer to helpe the flexion; and two muscles whereby the motion is restrayned when the hammer with the membrane is driuen with violence either inward or outward. For the bone which we compare to a Hammer hath a double motion, as *Arantius* elegantly obserueth, pressing forward and recoyling backeward.

Why more bones then one.

The double motion of the hammer.

Forward or inward according to the motion of the membrane whereto it is annexed, which membrane being shaken by the outward ayre is driuen inward, and vpward remaining so long gibbous on the inside til the Inbred ayre is affected with the sound, which ayre wandring through the circles conuolutions and burroughs of the eare, maketh the representations of the sounds to be receiued by the branches or tendrils of the fifth payre of Synewes, by which they are conueyed in a moment of time vnto the Braine. But that this membrane should not be driuen too farre inward, the Hammer opposeth it selfe. The Hammer determineth at the small cauity of the Anuill whereinto the head of the Hammer is articulated; wherefore the Anuill being a firme and stable bone, stayeth the inclination of the membrane, euen as sayth *Arantius*, in clocks there are certaine points of iron which wil not suffer the wheele to run beyond the number limited for the time of the day, And as the Anuill is assistant vnto the Hammer by laying a law vpon his motion; (and therefore hath two legs or processes whereby it is fixed to the stony bone and the stirrop) so also the stirrop standing vpon the cauity of the stony bone neere the circles as it were vpon a stable basis, doth elegantly sustaine vpon his head which is built in the maner of an arch, the longer processe or leg of the Anuill.

Inward.

The second motion of the hammer is outward, for the membrane of the Tympane

Outward.

together

together with the Hãmer, when the violence or conſtraint which before bare them inward is remitted do returne vnto their naturall ſtation; partly by a naturall motion whereby they recouer their former poſition when the violence is intermitted; partly by the muſcle which is an inſtrument of arbitrarie motion; for that muſcle is contracted toward his originall and ſo the head of the Hammer is ſeparated from his iuncture with the Anuile, and the recurued proceſſe of the Hammer beareth the membrane outward. But beſide theſe twoe bones, the 2. muſcles alſo of the inward eare doe aſsiſt the membrane, one of them againſt the inward impulſion, and the other againſt the outward expulſion.

The ſubſtãce of theſe bones

The ſubſtance of theſe bones is hard, denſe and ſmooth. Hard for that helpeth the hearing, as alſo addeth a greater ſtrength and firmitude vnto the membrane. They are alſo denſe and ſmooth for the better reception and tranſportation of the Sound; yet *Columbus* and *Coiter* are of opinion that the two firſt are within ſpongy and medullous. The third is ſo ſmall that there can be no holes perceiued therein.

How they differ from other bones.

And as theſe bones in forme and figure doe differ much from other bones of the body, ſo alſo and eſpecially they haue two notable diſsimilitudes or diſproportions from the reſt.

The firſt is that they are not compaſſed about with the *Perioſtium*, leaſt ſayth *Aquapendens* and *Placentinus*, they ſhould be vnfit for the reception of Sounds: for if you couer a hard body with a ſoft cloth and then ſtrike vpon it, it will not yeeld ſo ſhrill a ſound as it doth when it is bare or naked.

Againe, herein they differ from other bones as all Anatomiſtes doe concurre, that they are perfect and accompliſhed at the very birth, hauing the ſame magnitude then that they haue in olde age; partly becauſe man at all times euen from his Infancy hath greate neede of the Senſe of Hearing, as wel to learne to ſpeak as to gather knowledge; partly becauſe the membrane of the Tympane is as much ſubiect to danger by outward violence in our Infancy as in any time of our life. Notwithſtanding they are not ſo hard in Infancy as in old folke, for children are full of moyſture: whence it is that children do not heare ſo ſuddenly as grown men, becauſe to the exact perfection of the Sence there is required a notable drineſſe.

Why children do not heare ſo well as grown men.

Aquapendens addeth a third difference betwixt theſe bones and other bones of the body: for, ſayeth hee, theſe bones of the Eare doe hang ſuſpended from a membrane. Whence it commeth to paſſe that the externall aire together with the ſound is more eaſily communicated by the Hammer and the Anuill to the aire implanted in the eare: for Soundes are more liuely communicated to hard bodies, which hang looſe as you may perceiue if you tie a peece of Iron to a ſtring and ſtrike vpon it, it wil yeeld a ſhriller ſound then it will if it be not ſuſpended. But this conceit of *Aquapendens* ſounds but harſh in *Placentinus* eares.

Why they are hollow.

Theſe bones are alſo hollowe, as well to make them the lighter, as alſo to containe Marrow for their nouriſhment, whereto we may adde, that that which is hollow maketh a better reſonance.

Their vſes.

And albeit theſe three bones are of all others the leaſt in quantitie, yet by that which hath beene ſaide, we may conceiue that they are of great vſe and neceſsitie. In a word, their vſes are firſt to eſtabliſh and defend the membrane of the Tympane, leaſt it ſhould be torne either by inward windes gathered in the brain, or by the violent motion of the outward aire, as in thunder, ſhooting off Ordinance, or ſuch like.

Secondlie, they yeeld ſome aſsiſtance vnto the Senſe of Hearing, for by their help the Sound is conuaide by a kinde of conſequence or ſucceſsion to the auditorie Nerue. For vpon their commotion the Chord is ſhaken, the implanted aire is moued to receiue the Sound. Now the Chord could not haue beene ſo vehemently moued by the membrane alone as by the membrane and the bones; and ſo theſe bones together with the Chord being ſhaken by the appulſion of outward aire, doe conferre vnto the diſtinction of Sounds as the Teeth doe to the explanation of the ſpeach.

Anatomiſtes are here at a loſſe.

I am not ignorant that many men haue buſied themſelues to finde out the particular vſe of each of theſe bones, wherein what ſatisfaction they haue giuen themſelues, I know not; certainely to vs that reade their writings they giue but little. Their conceites being meere ſpeculations, & ſo intricate for the moſt part as if they did vnderſtand what they would haue ſaide, yet they haue not beene able to expreſſe themſelues vnto others. *Coiter* me thinks reſolueth very well that their exact hiſtorie eſpecially, for the vſe, is not

ſo

ſo curiouſly to bee ſought into, becauſe it is impoſsible that wee ſhoulde attaine further then a bare coniecture, and beſide ſomething would be left by vs for admiration, eſpecially where our vncertaine gueſſes cannot bring vs any great profite ſauing the ſatisfaction of an ouer curious conceite.

It remaineth that we ſpeake of that ſlender and neruous Chord which is within the membrane. It doeth not indeed compaſſe the membrane round about, but running thorough the middeſt thereof is faſtned to that ioynte where the ſtirrop is articulated with one of the Legges of the Anuill. This Chord if it be drawn out is thrice or foure times as long as it appeareth before it be drawne. For the ſubſtance *Euſtachius* taketh it to be a branch of the fourth coniugation. *Fallopius* ingenuouſly confeſſeth that hee knowes not what to cal it, yet reſolues to giue it the name of a Nerue, and with him *Coiter* conſenteth. *Ingraſſias* calles it a thred or a chord: *Aquapendent* a ſlender rope of the Nature of a Ligament, or, ſayth he, if it be not ſo nor any of the other aboue named, then is it a body of his owne kinde.

The Chord.

Diuers appellations.

Howſoeuer it be framed or of whatſoeuer, the vſe of it ſeemeth to be for pulſation, for as in a Drumme the ſound is made by the repercuſsion of the chord which is ſtreatched ouer the Vellam or the Skin, ſo in the eare ſayeth *Coiter* this chord receiuing an impreſsion by a beating made vpon it from the three bones, doth ſtrike the inward ayre whereuppon Senſation is made.

The vſe of it.

CHAP. XIX. *Of the Muſcles of the inward Eare*

THE Hammer beeing articulated to the Anuill with that kinde of articulation which we call *Ginglymos*, it followeth that their motion muſt be very obſcure, now they are moued together with the membrane at which the Hammer hangeth, vpward and downeward hauing one muſcle appointed for this motion within the membrane, another ſeated without it.

The internall muſcle [Table 11. figu 2. i] deſcribed firſt by *Euſtachius*, and ſcituated in the ſtony bone, is exceeding ſmall, there being in the whole body none leſſer: and yet the frame thereof is ſo elegant as no muſcle in the body may bee compared thereto. It ariſeth in the Baſis of the wedge-bone in that place where there is a hole made with a root of the proceſſe of the ſtony bone, and an additament of the nowle-bone.

The internall muſcle.

It taketh his originall from a ſubſtaunce much like a Ligament. Afterward it becometh fleſhy, and groweth a little broader euen to the verie middeſt. Afterward it is againe angulated or ſtraightned and produceth, *Euſtachius* ſayth but one Tendon. Whome *Coiter* and *Aquapendens* do follow. But *Placentinus* & according to him *Bauhine* ſay, they are two, very ſmall, [Table 11. fig. 5. below i] one of which is inſerted into the vpper proceſſe of the Hammer, the other into the necke thereof. But in Dogges a little before the inſertion it hath a fleſhy and round glandule a little depreſſed, which is not fixed to the membrane leſt if it were drawne by it ſelfe being very ſmall it ſhould be in danger of breaking.

His originall and progreſſe

This muſcle when it worketh draweth the head of the Hammer obliquely forward, and inward deduceth or inclineth it from the Anuill, and bending the proceſſe of the Hammer driueth the membrane outward.

That this is the vſe of this muſcle *Arantius* proueth by an experiment on this manner. If, ſayth he, in a greene head that is well diſſected till you come to this part, you drawe this muſcle with a ſharpe hooke toward his originall you ſhall finde it hath a double vſe: one that the head of the Hammer will manifeſtly recede or depart from the Anuil and be lifted vp, the other that the membrane will be driuen outward.

The vſe of it according to *Arantius*.

Now this motion which is made in the eares although it ſeeme to bee voluntary, becauſe it is accompliſhed by a muſcle which is an inſtrument of voluntary motion; yet it can hardly be perceiued by our ſelues, yea wee heare whether wee will or no, the reaſon is becauſe the muſcle is ſo very ſmal.

Neither doe we want examples of many muſcles whi ch we know aſſuredly doe worke as well while we ſleepe as while we wake, which yet wee cannot obſerue in our ſelues, but their motion ſeemes to be without our conſent, as we may inſtance in the muſcles of Reſpiration, of the eies, of the eie-lids, the bladder and the fundament. Yet in ſome men this motion is more euident, which alſo they can at their pleaſure moue or containe. The truth of this *Aquapendent* proueth on this manner. The motion ſayth he is Senſible, and with a kinde of noyſe, as if a man ſhould ſtretch three threds a little diſtant one from another, and ſtrike them with a Cittern quill as we do ſtrike an inſtrument; or as if a man ſhould ſcratch ouer-

Aquapendens his demonſtration of the motion of the muſcle.

ouerthwart the graine of a wanſcoate, or imagine it to bee like the noiſe that the Steele makes when you ſtrike fire out of the Flint. This motion is eſpecially perceyued vvhen a man begins to yawne, but in the beginning of it we heare a kinde of obſcure or dull ſound from the commotion of the aire, much like the noiſe that a ſtaffe makes when it is beaten againſt the aire. But this motion or noiſe in the aire many men do not obſerue; neyther doth it ſeeme to me ſaith *Placentinus*, to haue any vſe or to conferre at all to the Senſe of Hearing; for if there be a noiſe in the aire and at the ſame time a man ſhall ſtriue to ſtirre vp this motion, he ſhall heare the outward noiſe more imperfectly: And therefore this motion ſeemeth to happen either from the neceſsity of the matter, the Muſcles neceſſarily following the attrition of the Hammer againſt the Anuile, or elſe it was ordained by nature for the auoyding of vapours. For in Agues wherein many vapors do ariſe vnto the head this noiſe is frequently heard, which wee conceiue to be when as the vapours which fill the cauity of the eares are by this motion diſlodged, and yet we may vnderſtande that this motion is not altogether at our owne diſpoſition.

Bauhines demonſtration thereof out of the experiẽce in himſelfe.

In like manner ſaith *Bauhine* when the Eares are purged into the mouth by the paſſage that way opened, I am woont to perceiue in my ſelfe a kind of tickling within my mouth neere the roote of the *Vuula*, at which time if I often ſwallow my ſpittle, I doe manifeſtly perceiue by the noiſe that that motion is ordinarily ſtirred vppe in mine eares: and I perceiue likewiſe the foreſaide tickling to bee appeaſed when the matter by that meanes is ſooner purged into my mouth.

But how commeth it to paſſe that this motion is perceiued in both the eares at once? It may bee anſwered, that it happeneth in the eare as it dooth in the eye: for vvhen one eye is mooued, the other alſo inſtantly accompanieth it, as wee haue ſhewed before. A man would imagine that in large bodyed creatures this Muſcle might be better perceiued then in a man. But we find it farre otherwiſe; for although beaſts haue it, yet for the moſt part it is in them leſſe and harder to finde then in a man.

It is leſſe in great Beaſtes then in men.

Hee that is deſirous to finde out this Muſcle, muſt lightlie cut the Stonie proceſſe thoroughout the length, guiding his Knife by a Line which runneth there-through but not very high, beginning at that part of the proceſſe which is next vnto the Wedge-bone, for the muſcle runnes length-wiſe and ſo determines into the membrane of the Tympane.

How to finde this Muſcle.

The other Muſcle [Table 11. figure 1 and whoſe inſertion is at b] is ſituated without the membrane of the Tympane in the vpper part of the hole of Hearing about the middeſt thereof. Concerning the inuention thereof two excellent Anatomiſts of *Padua* in *Italy* doe contend. For *Hieronymus Fabritius ab Aquapendente*, whome therefore we call *Aquapendens* affirmeth, that he found it in the yeare 1599. But *Iulius Caſſerius Placentinus* auoucheth, that he obſerued it the ſeauenth day of March, in the yeare one thouſand fiue hundred ninety three. But out of queſtion they both haue deſerued wonderous well of this Art which of them ſoeuer was the firſt inuenter thereof.

The other Muſcle without the membrane.

Bauhins honorable remembrance of *Aquapendens* & *Placentinus*.

And becauſe, ſayth *Bauhine*, I would haue the world know how much I eſteem them both, I will ſet downe both their deſcriptions thereof beginning with *Aquapendens*, becauſe he is the Ancienter, not to derogate from the other, ſeeing I loue and honor them both. The one was my maiſter in the yeares one thouſand fiue hundred ſeuenty ſeuen, one thouſand fiue hundred ſeuenty eight, and one thouſand fiue hundred ſeauentie nine: the other in the yeare one thouſand fiue hundred ſeuenty nine was my friend and fellow-Studient, and this friendſhip to this day we maintaine by entercourſe of Letters, and ſhall do I doubt not ſo long as we liue. *Aquapendens* therefore hath it thus.

Aquapendens his deſcriptiõ of this muſcle.

Furthermore, this yeare 1599. I found a muſcle in the hole of hearing, cald [Tab. 10. fig. 9] which is without the membrane very ſmall, fleſhy and not without a tendon which proceedeth directly from the midſt of that hole or paſſage, till it be inſerted into the very center almoſt of the membrane on the outſide iuſt againſt the place where the Hammer on the inſide is faſtened to the membrane, which together with the Hammer it draweth outward. You ſhall finde this newe muſcle if in a greene head you cut the vtter Shell of the Bone which maketh the *Hole of Hearing* on both ſides, which you may beſt do with a Chizell and a Mallet and ſo remooue the bone carefully to the ſides, for ſo the Muſcle will appeare, and yet I haue not bene able to finde it in all my latter diſſections, although I eſteeme the neceſsity of it to be ſo great that I thinke it was rather the fault of my diligence then a defect in Nature. Thus farre *Aquapendens*.

Pla-

Placentinus describeth it on this manner.

In a man there is another Muscle situated in the vpper part of the hole of Hearing, [Tab. 11. fig. 1, a b] about the middest whereof the skinne and the Membrane which being implicated or folded together do inuest the saide hole, do euidently degenerate for the forming of this Muscle into a fleshy body: but almost membranous, distinguished or lined through with Fibres, hauing also a Tendon. The Figure of the muscle is round and in the progresse groweth slenderer by degrees, and so passeth directly on vnto the Tympane. It is inserted not into the outside of the Membrane nere the center; but the Tendon (which it transmitteth with a double extremity or termination into the cauitie of the stony-bone betwixt the Tympane and that part of the temple-bone from vvhich the bonie ring proceedeth) is fastened on the inside into the heade of the Hammer, betwixt the vpper and the lower processes thereof. The inuention of this Muscle if I attribute to my selfe I shall not defraud any man of his due commendation, for I obserued it the seuenth of March in the yeare 1593. in the presence, &c. Thus far *Placentinus*. *Placentinus* description.

Aquapendens his opinion of the vse of the Muscles.

The vse as well of the Internall as of this externall Muscle *Aquapendens* thus expresseth.

The vse of these Muscles is for the securitie of the Membrane, for becausse it might haue bene broken or torne either on the inside or the out, Nature prouided a strength

Table 11. *Sheweth the Muscles placed in the cauity of the eares, with some other cauities and bones of the eares.*

or

or defence in both places. For on the outſide the aire beeing violently mooued might haue broken the membrane by thruſting it inward, and on the inſide by beating it outward; in the outſide the externall aire which with violence togither with the ſound ruſheth into the eare; on the inſide the aire which thorow the mouth getteth into the eare doth forcibly ſometimes driue the membrane from within outwarde; and in this manner is the membrane ſtretched ordinarily in yawnings, blowings of the noſe, retention of the breath, ſtrong contentions, lowd voices, the excretion of excrements, and ſuch like violent conſtraints. The externall Muſcle therefore when the Membrane is driuen inward draweth it backe, and as it were recalleth it into the right place. In like manner, the internall Muſcle retracteth it inward when it is turned or driuen outward. And theſe are the neceſsities for the ſatisfaction whereof Nature ordained theſe two elegant muſcles, to wit, for the preſeruation of the Membrane.

The reaſon why the cuſtodie of the Membrane was committed to a Muſcle, that is, to an inſtrument of voluntary motion is rendred on this maner. If any other tie but that of a Muſcle had bene made the *Cuſtos* or *Vindex* of this Muſcle, ſuch a tie muſt haue held it alwayes ſtretched or tentred alike, and ſo the Membrane would rather haue bene more endangred then any whit ſecured. Beſides, it was verie neceſſarie that as the impulſions of the aire vnto the Membrane are diuers, ſo there ſhould be a varietie of power in that that was to curbe or limmit thoſe diuers motions or impulſions. Such a varietie of power cannot bee imagined to bee in anie Ligament but onely in Muſcles which make their operation with a certaine Analogie or proportion to the finall end which Nature entends, or according to meaſure; contracting and relaxing themſelues more or leſſe as neede ſhall be, accommodating their motion diuerſly according to the diuers impulſions of the aire; for they ſuffer the Membrane onely ſo to receiue the offered violence, that neither the violence might be altogethet withſtood but that the membrane might yeeld therto, nor yet the Membrane be outraged by ſuch violence. In a word, theſe muſcles partly by yeelding and giuing groũd, partly by obluctation or oppoſition do ſecure the Membrane from being torne and rent aſunder. Thus far *Aquapendens*.

Placentinus thus. The Muſcles of the inward eare doe one of them aſsiſt the Hammer againſt internall impulſions, the other againſt externall. The outward muſcle which I founde out, that ſendeth his Tendon into the cauitie of the Stony bone and ioyneth it ſelfe with the greater proceſſe of the Hammer, draweth that part of the Hammer outward which inclineth inward, and ſo moderateth the compreſsion thereof made vppon the Anuile, that it is a defence againſt the internall Muſcle.

Placentinus opinion of the vſe of the muſcles.

The Internall which ariſeth from the Wedge-bone and paſſeth into the cauity of the Stony-bone vnto the Head of the Hammer into which it is inſerted, ſuccoureth the ſame againſt the former when it is driuen inward, defining and limiting his introceſsion. For when the Tympane by an irruption of outward ayre, is together with the Hammer driuen inwarde, this muſcle reſiſteth their motion that the Tympane and the Hammer ſhould not be conſtrained beyond their Tether & ſo ſuffer laceration. Thus farre *Placentinus*.

Varolius concerning this matter (for we account him alſo among our claſsicke authors, eſpecially concerning the head) writeth on this manner.

Varolius his vſe of a muſcle in the ear.

Although, ſaith he, the ſound do mooue the Senſe of Hearing whither wee will or no, yet there is in vs a kinde of voluntary Animadverſion which wee exerciſe in all our ſenſes at our owne pleaſure when we would iudge curiouſly of any ſenſible thing. Wherefore as by the helpe of the muſcles of the eye men do voluntarily direct the center of the Criſtalline toward the obiect which they attentiuely behold, ſo within the organ of Hearing there is placed a ſmall muſcle, which ariſing from the fore-part is inſerted into the articulation of the triangle (ſo he calleth the *Stirrop*) with the Anuil: when this muſcle is contracted, the Triangle or Stirrop is drawne a little forwarde, the ioynt of the Anuile with the Hammer yeelding thereto, and approacheth more directly to the Center of the Tympane, and at that time we heare with more attention and better iudgement, like as wee are able to ſee the leaſt viſible obiect when we ſtedfaſtly beholde it by a line concentricall to the *Horny Membrane*, the *Pupilla* and the *Criſtalline humor*. Some haue imagined that the ſmall bones of the eares diuerſly mooued by this muſcle, doe make within the organe of Hearing many and different ſorts of ſounds, whoſe opinion we thinke ſufficiently confuted by the former aſsignation which we made of the vſe of the muſcle. Thus farre *Varolius*.

CHAP.

CHAP. XX. *Of the Cauities of the Stony-bone.*

ALbeit wee purpose in the Booke of Bones as particularly as wee can to follow their history; yet because this Stony bone and the dissection thereof is most necessary for the vnderstanding of the manner of the Sense of Hearing. VVee haue determined to make our particular description thereof in this place; and to passe it ouer with little more then bare mention in the booke of Bones. Why we intreat of this bone here.

Although therefore (as before is sayd) the Stony bone is within altogether *Canernous* and spongy, and that the Antients haue made mention of one only Denne or Cauity there in: yet wee will reckon vnto you three notable ones and of great moment, which also the *Neotericks* or later Anatomistes haue called *Dennes* and *Caues*.

These Dennes or Caues are formed in the middest of the stony-bone where it swelleth most, to contayne the Organs of Hearing, that is to say, the mẽbrane, the three smal bones, the internall muscle, the chord, the auditory nerue and the in-bred ayre, which also is called the internal *medium* of this Sence. All which Caues may more distinctly and distrietly bee demonstrated in children, then in growne men. *Placentinus* findes them also verie conspicuous in Birds. They haue each of them proper names borrowed from externall things: the first is called *Concha* or *Tympanum*, because it is like the shell of a winke or a Taber. The second is called *Labyrinthus*, because of the turnings therein. And the third is called *Cochlea*, because it is like a Snailes shell. 3. Cauities. Their names.

The first [Table 10. fig. 2 [h] from [c] to [s] Table 11. [qr]] cauity is layd open, when the membrane of the Tympane is taken away. It is called *Concha*, as we sayd euen now, because it is like a VVinkle or Periwinkle, so acknowledged by *Aquapendens*, *Placentinus*, *Arantius*, & our Authour *Bauhine*, although I knowe there is great contention against *Aristotle* in this point, who seemeth first to haue giuen this name to this cauity. But wee stand not vppon names so much, so we know the thing signified by the name. The better appellation as me seemeth is a Tympane, because this cauity couered with his membrane resembleth a Drumme or Taber, for when the membrane is strucken by the Sound it resoundeth again as a Drumme if it bee beaten by reason of the ayre therein contayned rendreth a great sound. The first cauity. The reason of the name.

Coiter reprehends *Fallopius* and *Platerus* for this appellation, because, sayth hee, in this cauity there are holes, & windowes, and diuers windings which a Drumme hath not. To whome we answere, that in men it hath the name of a Drumme or Tympane from the vse; but in bruite beastes not onely from the vse but also from the figure because in those creatures that chaw the Cud it is very like to a Turkish Drumme. This cauity is also called by *Coiter* and *Placentinus* the *Bason* and the *Denne*. It is excauated or hollowed in the beginning of the stony-bone, betwixt the roots of the *Mammillary* processe, and the place where the head of the Iaw is inserted or fastned to his ioynt. The vtter part thereof regardeth the hole of Hearing from which it is onely separated by the membrane [Table 10. figu. 2. from [b] toward [c].] *Coiters* obiect. Answered.

Hence it is that if the inside of the eare be inflamed or vlcerated, vppon the motion of the lower iaw the patient is payned in his eare. Note.

The inner part of the cauity is by a thin scale distinguished from the hole of the sleepy artery [Table 10. fig. 2. from [h] to [t].]

This first is the greatest cauity of the three, and by a succesiue ingresse or continuity of passage is ioyned with them, by which meanes it is able to containe a greater quantity of in-bred ayre, & also receiue at the same time diuers sounds comming from diuers quarters.

But because the internall ayre must first be mooued by that which is without, and then transport the image of that sound wherewith it is moued to the Auditory nerue, it was verie necessarie that it should be purged and kept pure from any stayn of corruption, that like a neate glasse it might represent the image offered vnto it. For this purification and expurgation of the inward ayre, Nature hath placed in this cauity diuers instruments: some seruing for Pulsation, some for Traiection, and some for Expurgation. For Pulsation serue the three bones, the chord and the muscles. For Traiection or conduction vnto the other cauities serue two perforations commonly called *Feneſtellæ* or the VVindowes. For Expurgation there is a passage which leadeth into these pallat. All the particles did require a large cauity; whence it was that Nature framed this stony bone long and round, that so it The organs in this cauity.

Why this is single. A witty conceit of *Aquapendens.*

might containe the more. Furthermore, this cauity is but ſingle, whence it comes to paſſe that though there be many noyſes made together, yet they are at the ſame time receiued. For if this firſt cauity had bene diſtinguiſhed into many dens, neither would the ſounds haue bene receiued at the ſame time nor after the ſame manner intertained and iudged of by the faculty, for the diuerſity of reception would alſo haue induced a diuerſity of apprehenſion, as *Aquapendens* very wittily hath obſerued.

The fashion of the cauity

The interior ſuperficies or inner ſurface of this cauity is vnequall, being in ſome parts depreſſed and thrilled through, in others knotty and ſwelling. Immediatly behinde the membrane it runneth vpward toward the forepart, where alſo it becommeth narrower, afterward it is dilated and tendeth backeward toward the top; then as if it were another cauity it is produced or lengthened downeward; which part ſaith *Coiter*, in a man is like a bladder. [Tab. 11. fig 8. and 9.] In a calfe like a waggeners budget, in a kid and lambe like a market womans pouch. It is alſo rough and ſpongy; rough, that it might receiue the ſounds and not reflect, returne or double them, for if it had bene leuigated, that is, ſmooth and equall like the arch of a Church, it would haue returned an Eccho. Spongy alſo, that if at any time the noyſe ſhould happen to bee ſo ſtrong that it might offend the hearing, the force thereof might be abated in thoſe ſmall holes. Moreouer, in that ſpongy poroſity the Inbred Ayre is laboured and brought to perfection. But when I ſay, it is ſpongy, I would not haue you conceiue that it is ſoft as a ſponge but porous, for otherwiſe it is exceeding hard and ſtony, thereby yeelding and returning a quicker ſound.

Why porous or ſpongy.

How lined.

Againe ſome parts of this cauity are lined ouer with a membrane produced from the *Pericranium*: for after the *pericranium* hath framed the membrane of the Tympane, it is duplicated and diuerſly diuided, ſo as ſome of it doth inueſt certaine parts of this cauity.

The neceſsiry of the parts of this cauity.

But becauſe this cauity was deſtined for the reception of the implanted or Inbred Ayre, which was to receiue the outward Ayre ialtered by the ſound, it was very neceſſary that it ſhould receiue ſome kind of percuſsion: but being by the membrane diſtinguiſhed or diuided from the hole of hearing, it could not receiue the alteration of the outward Ayre without ſome other helpe, which helpe is pulſation, and that pulſation is accompliſhed by the three bones, the chord and the muſcles.

Now that the internall Ayre being affected by the pulſation of the outward Ayre altered by the ſound, might carry this affection vnto the ſenſe, there was made certaine canales wherein the inward Ayre might be conuayed vnto the Auditory nerue, to wit, the two *Windowes* with a paſſage into the *Labyrinth*. Furthermore, it was alſo neceſſary that this implanted Ayre ſhould be preſerued pure, as alſo bee cheriſhed and ſuſtayned by the Ayre which we draw in at our mouthes, to which purpoſe Nature hath created a canale or paſſage out of this cauity into the pallate, by which it is purged and receiueth new Ayre for his perpetuall nouriſhment. Of the inſtruments ſeruing to pulſation, we haue entreated at large in the ſeuenteenth & eighteenth chapters; of thoſe ſeruing for expurgation very particularly in the nineteenth chapter; and both we haue repeated in this. It remaineth now that we proſecute thoſe Organes which ſerue for Traiection or tranſmiſsion of the affected Ayre vnto the auditory nerue, and ſo to the firſt ſenſator.

CHAP. XXI. *Of the two windowes called Feneſtellæ, and the watercourſe in the firſt cauitie.*

The firſt.

IN this cauity there are two holes very ſmall, which ſome men call *Feneſtræ* or *Feneſtellæ* the windowes. Theſe regard the orbe of the hole of hearing as from a higher place. The firſt which is the foreward and the higher and looketh toward the face, [Tab. 8. fig. 4. and 5. F. Tab. 10. fig. 2. k.] being as it were in the middeſt of the cauity, is of an Ouall figure or like an Egge, and therefore is it by ſome Anatomiſts called *Feneſtra oualis*, the ouall window.

Feneſtra oualis

It is ſomewhat long and flatted on the ſides, and in the backe ſide it openeth it ſelfe into the *Colchea* or the laſt cauity with a large mouth and becommeth ſo like the forepart of the *Colchea* that a man cannot tell whether that this Ouall window open into the *Colchea*, or the *Colchea* into it. This alſo ioyneth it ſelfe with the poſterior hole, and paſsing inward is dilated, and maketh as it were a Market place or is like the cauitie of a mettall Mine, (for thus the Anatomiſts haue pleaſed to compare little things with great) from which many ſtreets, wayes or burroughs do runne. Vpon this lieth the baſis of the ſtirrop, and for the moſt part cloſeth it vp.

The other hole or window is the poſterior and lower. [Tab. 8. fig. 3. 4. G. Tab. 10. fig. 2.

2.l.] It is rounde and leſſe then the former and ſomewhat narrower in a man; but in a Calfe and a Sheep ſayth *Placentinus* it is ſomewhat larger, and a little extuberating or bunching out; alwaies open it is and declining toward the backeſide of the cauity, and yſſueth together with the former through the bone making a double canale.

Betwixt theſe two windowes [Table 10.figur.2.k and l] aboue the lower hole is there a little knub or protuberation, which together with the round hole and the ſtrutting bunch placed vnder the vpper part, may be compared to the little boſſe (ſaith *Placentinus* and before him *Veſalius*, *Coiter* and *Platerus*) wherewith they vſe to adorne the cheeks of a horſes bit. In this knub lieth the chamber of the third cauity which is called *Cochlea*, of which wee ſhall heare more in the next Chapter.

The vſe of theſe windowes is, by pulſation to receiue the ſound communicated to the implanted ayre, and to tranſmit the ſame to the other cauities that follow. Their vſe.

The lower hole is cleaued into a double pipe which lie one vppon another [Table 10. figu.2.ii] and are deuided onely by a thinne bony ſcale, the one of them together with the Quall window paſſeth to the *Cochlea*, the other goeth into the Labyrinth or the ſecond cauity of the ſtony bone. The more forward of theſe admitteth a ſurcle of the Iugular veine, and ſendeth out a braunch of the firſt coniugation. The *poſterior* is compared to a Water-courſe [Table 8.fig.3.x Table 10.figu.2.g] becauſe it is like the pipes wherein water is conuayed, imagine it to be in a Serpentine Still, ſome call it the Saylie pipe. The Auntients and *Galen* call it *Cæcum meatum* the blinde paſſage, others *Capreolaris*, that is writhen or intorted, not becauſe it is blinde, but becauſe if you put a Hogges briſtle into it, it will hardly finde an yſſue. And truely in the dry skull of an Oxe you cannot finde way for a briſtle by any meanes. The water-courſe.

It paſſeth writhen, firſt forward, then backward and obliquely aboue the hole of the firſt cauity. From thence turning downewardes it determineth into the fift hole of Hearing, [Table 10.figu.2.αβγδ] it is full of holes. In the beginning is that which is marked with [α] common to it with the vpper part of the paſſage of the auditory nerue. Afterward in the middle of the paſſage on the outſide in the forepart of this canale [δ] it maketh the *fift hole of Hearing* and letteth fall an arterie; ſo alſo in the inſide [γ] at the beginning of the ſecond cauity it opneth it ſelfe. In the end alſo it hath another hole [β] which determineth into the 3. bone of Hearing. Through this canale is the greater part of the auditory nerue as alſo an artery diuerſly deduced and dilated. For becauſe it was neceſſary that the branch of the nerue of the fift coniugation ſhould grow hard, it was alſo fit it ſhould be conuayed thorough the hardeſt, drieſt and moſt torted paſſage, eſpecially ſeeing there was no other way where through it might be conuayed. The paſſage of it.

CHAP. XXII. *Of the Labyrinth and the Cochlea or Snaile-ſhell, that is, of the ſecond and third Cauities of the Stony Bone*

THe ſecond Cauity becauſe it is full of windings and turnings like a Conny-burrough, is called *Labyrinthus* and the Mine. It is inſculped or excauated in the *poſterior* and *anterior* ſides of the ſtony bone or in the root of his proceſſe, and is diſtinguiſhed or deuided from the hole of the nerue of Hearing, onely by a thinne ſcale. [Table 10.fig.2.betwixt m and c] It is round and leſſe then the former: and when it hath (vnder the knub and behind the Oual window) ioyned it ſelfe to the following cauity; attayning inward it is dilated & maketh as it weere a Market place, or the broad floore of a Mettall Myne as before is ſayde; from which many wayes run out, which proceeding thorough the hard ſubſtance of the bone like a hollowed circle, doe againe returne into a large Chamber. The 2. cauity. The forme.

Theſe wayes we call burroughes with *Fallopius*, *Coiter* and *Platerus*, or with *Placentinus* bony Semicircles. [Table 8.fig.4.and 5.nnn Table 10.fig.2.m 1.2.3. and particularly m with the Characters 1.2.3.fig.6.V] Of theſe we make three, which do ſo paſſe that two of them do twice interſect theſelues with right angles, but the more manifeſt interſection is made aboue the top of the third cauity where the hole endeth which receiueth and tranſmitteth the nerue of the fift coniugation. *Cuniculi.* The interſections.

In their originall they are ample or large and become narrower by degrees, becauſe it was not fit that the Sound ſhould paſſe through a broad ſpace; afterward running through the ſubſtance of the bone in circular reflections, they returne to their beginning, yet ſo that in their whole progreſſe they neuer manifeſtly open one into another.

The first. One of these is the lower which runneth from the forepart of the cauity diuerting or turning aside outward yet still in the same cauity, afterward it is reflected and runneth thorough the *posterior* angle.

The second. The second issueth out of the same *anterior* angle, and arising vpward after it hath made a semicircle, it returneth through the *posterior* angle.

The third. The third ariseth and determineth in the backeward angle of the cauity: for beginning there it perforateth the bone with a circular cauity tending outward, and so returneth thither againe. And all these in young Infants may be separated whole from the cauity and from the crust wherewith the bone is lined, but in time they grow stony & are vnited. These canals or burroughes could not be made long because of the shortnesse of the stony bone, although it had beene very profitable, because length maketh the sound bee better perceiued. VVherefore Nature recompenced their shortnes with circumuolutions, and indeed the gyrations do better helpe the Hearing then length would haue done, because in them as it were by degrees the sound is by little and little laboured, and ascends broken and diuided into the braine. Furthermore, the burroughes in their inward superficies are inuested with a very soft and fine membrane.

The reason of the meanders

Their perforations. These burroughs by their egresse and regresse into this cauity make sixe holes: beside, from the first cauity into this are two holes, and moreouer certaine small ones from the lower hole of the auditory nerue and from the common canale. [Table 10. fig. 2. γ] The cauities or holes, saith *Aquapendens*, are so innumerable and intricated one with another, that it may well be called a Labyrinth. For their number they are rather to be admired then numbred, neither can a man finde any order in them, and if any man shoulde attempt any such thing, it were a worke of a vaine and addle witte, albeit *Placentinus* thinketh it fæsible. For cutte any parte of this bone, and beside the vtmost crust you shall finde the rest of the whole bone to be full of holes, pores and dennes, yea altogether spongy, as is touched partly before.

The vse of conuolutions. The vse of the Conuolutions and Meanders is, that the sound being conuayed through so narrow passages might be more sharpe and not bee dissipated; and this wee may see in Instruments of musicke, for a Flute or Cornet by how much it is the longer and the narrower, by so much is their sound more shrill: the reason is, first because the ayre remayning quiet and at rest in the canale doth more easily receiue the alteration proceeding from the sound then it would doe if it had scope wherein it might be troubled and disturbed. Again, the aire concluded in a narrow roome is not dissipated but vnited, and so remayning yeeldeth a greater and quicker representation of the sound vnto the nerue, then it would do if it were dispersed.

The third cauitie. The third cauitie is called *Cochlea* or the Snaile-shell from the sinuing obliquitie of his passage; which elegantly resembleth the winding of a Snayle or Periwinke shell [Table 8. fig. 4. and 5. O Table 10. figu. 2. vnder n] especially if you take off the vpper part of the shell till you come to the narrower part thereof where the scruing begins to be thick. *Vesalius* calleth it *Antrum Buccinosum*, the Den like a Trumpet. The Antients called it the blinde hole or the blinde cauity, because they thought it had no through passage. But the truth is, that though it be much intorted and writhen, yet it hath an yssue in the middest, in that place where the gyrations are fastned from the beginning to the end, and this yssue is narrow and direct. For if this cauity had beene blinde without an out-let, the ayre being beaten could not haue attained to the nerue of Hearing.

The appellations.

Where situated. This is farre lesse then the former two, scituate in the forepart of the processe vnder the knub of the first cauity, that it might meet with the Soũd which proceedeth from behinde forward, and is distinguished from the canale, which wee sayd was like a watercourse (placed in the middest of the stony processe) by a thinne bone like a bridge [Table 10. fig. 2. betwixt n and f.]

The figure. It is long and crooked and hath three gyrations sometimes, sometimes foure, one of them receiuing another after the manner of the *Cochlea* or Snaile-shell, by which it is intorted somewhat inward and downeward. But the broader scrue standing highest receiueth the nerue; the narrower standing lowest determineth in the cauity of the bone, and worketh it selfe also a passage. Into this endeth the hole of the first cauity called *Feneſtella oualis*, which *Platerus* calleth the lower hole and *Placentinus* the vpper [Table 10. fig. 2. l] I meane into the greater gyre of this bone.

This bone of the *Cochlea* or the Snaile shell consisteth of two kinds of circles, whereof one

one is made of a bony ſubſtance very thin and dry, which may eaſily be crumbled, and on euery ſide like a Snake rowled vp into boughts. The other was firſt propounded by *Euſtachius*, which is made of a ſoft & mucous matter yet firme, and hath I know not what kind of ſandy matter mingled therewith. It ariſeth out of the middle ſpace of the firſt conuolutions, as it were out of a large baſis, and being by degrees extenuated, endeth in a ſharpe point; but it aſcendeth not ſo high as that it toucheth the circumference of the bone wherinto the firſt gyrations doe determine. *Euſtachius.*

This wonderfull prouidence of our Creator, *Empedocles* as *Galen* witneſſeth in his booke *de hiſtoria Philoſophica*, did firſt intimate, when hee ſaith that the ſenſe of hearing is made by the impulſion of the ayre, or of a ſpirit which ſtriketh & beateth the part like a Snailes ſhell, ſuſpended within the eare like a bell. And with him agreeth *Ariſtotle* in the eleuenth chapter of his firſt booke *de hiſtoria Animalium*, where he ſaith, that the inward eare which is like the contortions of a Snayles ſhell, endeth in a bone which is like the outward eare. *Empedocles.* *Ariſtotle.*

This third cauity as alſo the ſecond and the burroughs thereof, are inueſted with a ſoft and thin membrane, after the ſame manner that the ſockets of the teeth are. *Veſalius* ſaith it is a part of the nerue of the fifth coniugation, and that it doth inueſt but ſome parts onely of the cauity, not all throughout. Into this cauity as well as into the former, do run three or foure holes ſo ſmall that a haire will ſcarſe paſſe through them, iſſuing out of that canale through which we ſayd the auditory nerue doth paſſe; through which holes certain nerues of the fiſt coniugation, or at leaſt their faculty is communicated to the foreſayde membrane. So differeth *Bauhine* from *Veſalius*. The mebrane inueſting this cauitie. *Veſalius.* *Bauhine.*

And although it is generally beleeued that the ſenſe of hearing is eſpecially made in the firſt cauity, yet it cannot be denyed but that it is alſo made in the others; ſeeing into them as is ſayd, there are ſurcles of nerues deriued, and in them alſo Animall ſpirits and inbred ayre is contained. Notwithſtanding the two hindmoſt cauities were rather made to hinder an Eccho or reflexion of the ſound to the firſt cauity. And whereas theſe cauities haue holes of diuers magnitude, length and figure, it is reaſonable to thinke that they were ſo framed for the difference of ſounds. For a baſe ſound and a great quantity of ayre require a large hole. The vſe of theſe cauities. Why perforations are of diuers kinds.

The length prohibiteth the Eccho and the reflection of the ſound, wherefore the greater ſound required longer canales, and the leſſer ſhorter, that the ſound in them might as it were, be appeaſed, and an Eccho prohibited. The varietie of the figure maketh much either for the naturall delation or tranſmition of the ſound and the ayre, which runneth for the moſt part through circled meanders; or that the ſound in them might reſt: now we may eaſily imagine that a ſound will ſooner ceaſſe or bee appeaſed when it runs through many turnings or gyrations then it would doe if it were conueyed by a ſtreight line.

But the vſe of this third cauitie *Coiter* elegantly ſheweth and confirmeth by an inſtance in a circled inſtrument, put caſe it bee a Sackebut. For if a man lay his eares to the holes of ſuch an inſtrument, hee ſhall here a wonderfull whiſtling and hiſsing noyſe and murmure: where if a man blow into it with his mouth it will ſound like a Trumpet. And thus much concerning the ſtony bone and the cauities thereof: now we proceed. The vſe of the 3. cauitie after *Coiter*.

CHAP. XXIII. *Of the Nerue which ariueth at the Eares.*

AT length we are come to the Auditory Nerue which maketh that coniugation which is commonly called the fift, [Tab. 21. lib. 7. fig. 1. 2. a. Tab. 15. lib. 7 fig. 20. M.] It iſſueth out of the tranuerſe proceſſe of the *Cerebellum*, and is a thicke and large nerue; therefore neereſt of all to the After-braine becauſe it was to conuey a great quantity of Animall ſpirits. It inſinuateth it ſelfe into the firſt hole of the ſtony bone, which a large perforation and made of purpoſe within the ſcull for the tranſmiſsion of this nerue, which it hideth all the way it runneth forward, till in the middle almoſt of the ſtony proceſſe it is diuided into two vnequall parts: the one large & ample, the other ſmall but harder; harder I ſay then the other, not through out the length of it, but onely in that part which is longer then the former. For, that wee may ſay ſo much by the way, the ſoftnes or hardnes of a nerue dependeth vpon 3. things. Firſt, vpon the originall, ſo thoſe nerues that ariſe out of the Braine it ſelfe are the ſofter, thoſe that ariſe out of the After-braine or out of the ſpinal marrow are the harder. Secondly, vpon their diſtance, as they are farther from their originall, or neerer vnto it. Where it ariſeth. How many waies a nerue becomes hard and ſoft.

So the Opticke nerues are the ſofteſt of the whole body, becauſe they are neereſt to their originall; the nerues of the hands and feete the hardeſt, becauſe they are fartheſt off. Or, thirdly, it hangeth vpon their contaction: for frō their contactions with hard bodies as bones & griſtles, or with ſoft as fat and veſſels, they become harder and ſofter as *Placentinus* hath obſerued, but this by the way. This ſlender production of the nerue through the vpper hole of the forementioned paſſage entereth into that ſecret bony canale which we called the *Watercourſe*, and ſo creepeth toward the forepart of the head. Afterward it is reflected and entereth into the firſt cauitie, and falling downeward and backeward, it iſſueth out of the bone at the roote of the lap of the eare, and is ſubdiuided into three eſpeciall branches. The larger and vpper runnes out into the foreſide and the backeſide of the roote of the outward eare. The lower deriued through the iaw, is diſtributed into the *Maſſeter* muſcle and the firſt muſcle that mooueth the cheeks. The third which is the middlemoſt is very ſmall and Capillary, and is diſſiminated into the glandulous and membranous parts about the roote of the eare. There are alſo other threedy ſurcles which are ſpent into the muſcles of the larynx or throtle, and of the bone *Hyois*. And this is the cauſe of the conſent betweene the eares, the tong and the larynx. Hence alſo it is that when the auditory nerue is originally and in the firſt conformation obſtructed, thoſe that are borne deafe are alſo dumbe; and thus much of the leſſer part of the nerue.

3 branches.

Small threds of the auditory nerue.

Why thoſe that are born deafe are alſo dumbe.

The thicker part of the nerue which is ſoft, and is properly the *Nerue of hearing*, becauſe it of it ſelfe is the cauſe of this ſenſe; is led through the hole of the foreſayd paſſage and runneth out into the dens or caues of the ſtony proceſſe: yet the larger branches doe determine in the firſt cauitie as being the largeſt and of moſt vſe, where they are dilated like a membrane and make the chiefe inſtrument of hearing. Wherefore the receiued opinion is, that in this cauity the ſenſe of hearing is eſpecially adminiſtred, becauſe into it the Animall ſpirit entreth through the nerue, & is there mixed with the Inbred ayre. Out of this cauity through ſmall proforations of the foreſaid cauitie run certaine ſmall threds into the other two cauities, which are communicated to the membrane wherewith they are compaſſed.

The very nerue of hearing.

The vſe of it.

The vſe of this nerue is (according to *Galen* in the ſixth chapter of his eight booke *de v. ſu partium & Auerrhoes* 2. *Collect.*) to be the Organ of hearing, and to receiue the ſenſible obiect that commeth from without, and to leade the images of the ſounds vnto the braine as vnto their competent Iudge and Cenſor ſaith *Laurentius*.

The Chord.

But from a branch of the fourth coniugation of the braine, there departeth a very ſmall ſurcle, which with a winding paſſage entereth into the cauity of the Eare neere the bony canale which goeth to the palate, then it cleaueth obliquely to the Tympane, and after to the Hammer aboue the inſertion of the muſcle, and proceeding on perforateth the ſtony bone in the backeſide of the hole of the hearing: then, a little reflected, it creepeth downeward till it meete and ioyne it ſelfe with a ſmaller and harder branch of the fift coniugation. This *Euſtachius* calleth a Nerue, others call it the chord or thred which, ſay they, runneth through the middeſt of the membrane of the Tympane; but whence it ariſeth and whither it would, or whether it be a nerue or an artery, they freely confeſſe that they are ignorant.

Euſtachius.

CHAP. XXIV. *Of the Implanted or Inbred Ayre.*

Galen in his ſeuenth booke *de Placitis*, ſpeaking of the inſtruments of the ſenſes determineth; that the inſtrument of ſight is lucid or bright, that of the hearing aereall, that of the Smell vaporous, that of the Taſt moiſt, and that of the Touch earthy. Wherefore when wee ſay that the inſtrument of the hearing is ayry, or like vnto ayre, we vnderſtand that it is a part of mans body (taking the word Part in a large ſignification) which imitateth the nature and condition of the ayre.

The obiects of all the ſenſes.

Plato.

How this aire is generated.

This ayre of which *Plato* among the Philoſophers made firſt mention, is ſeated in the eares from the firſt originall of our generation in the wombe of our mothers. I meane as ſoone as there were emptie cauities hollowed in the bones, all which are filled with this ayre. And therefore the ancient Philoſophers and Phyſitians, yea *Ariſtotle* himſelfe in the eight chapter of his ſecond booke *de Anima*, and the 83 text called it συμφυὴς, or *Inbred*. Others call it *Congenit*, *implanted*, *complanted* and *inaedificated*. It is made of the ayry part of the ſeede and that very pure, to which the pureſt ayry part of the mothers blood applyeth it ſelfe, as to a body moſt like vnto it ſelfe, ſaith *Archangelus*.

The names of it.

This

This aire is conteined in the cauities of the ears; which may be proued, becauſe all the dens and cauities excepting the firſt in which are the ſmall bones the Muſcle & the Chord are empty, ſeeing therfore there is in Nature no vacuity, it is neceſſary that theſe empty cauities muſt be full of aire. Where conteined.

This aire is thin, pure, without any ſound at all, immoouable, plentifull & ſeparated from the externall aire. *Thin & pure* that it might more readily and more perfectlie admit any externall ſound, for through a craſſe and cloudy aire the ſound is not ſo freelie caried, but heard with more difficulty; whence it is that a mans voice in winter is baſer then in Summer, becauſe as ſaith the Philoſopher in the 17. Probleme of the 11. Section both the inward and the outward aire is thicker in winter then in ſummer, now beeing thicker it is mooued more ſlowly. The nature of this aire. Pure. *Ariſt. Problem.*

This aire is *without any ſound*, and therefore in the night we may hear better becauſe there is no noiſe ſtirring, as *Ariſtotle* teacheth in the 33. probleme of the 11. ſection. Adhereto that which he in the ſame place addeth, that in the day time the aire is denſe, becauſe it is filled with light and the beames of the Sunne, but in the night more rare, becauſe the fire and the beames are departed thereout. without ſound *Ariſt. Problem.*

Wherefore the outward aire which is altred by ſounds, and like a waue of the Sea boundeth to the eares is not admitted into the inward eare, neyther dooth it touch the implanted aire; for if it had, the ſenſe of hearing would haue bene imperfect and the Inſtrument would ſoone haue bene vitiated, which *Ariſtotle* proueth by an inſtãce in thoſe that yawne, in the 29 probleme of the 11. ſection, and in his fift booke *de generatione animalium* and the ſecond chapter. For when we yawne we cannot heare ſo diſtinctlie, becauſe much of the aire we breath forth getteth into the ears, inſomuch that we may ſenſibly perceyue the motion thereof; for when the internall aire reſiſteth the occurſation of the outward there ariſeth a noyſe in the eares, which noiſe as alſo the circumaction or diſturbance of the ſpirit hindreth our hearing whilſt it be agayne appeaſed. *Ariſtotles* inſtance. Why we cannot heat well when wee yawne.

Againe, it was neceſſary that this implanted aire ſhould be *immoouable* by it ſelfe or of it owne nature, that it might exactly receiue al the differences of ſounds, of *motions* ſaith *Ariſtotle* in the eight chapter of his ſecond booke *De Anima*. Others ſaie, it is immooueable becauſe it is not mooued by any other but remaineth alwayes the ſame in the eares. Others becauſe it hath no naturall ſound but is fit to receiue all differences of ſounds ſaith *Laurentius*. But that the inward aire ought to be quiet and immoouable may bee prooued by the indiſpoſition we haue in our hearing when we are troubled with hiſsing or ſinging noyſes in our heads. Yet is this aire mooueable not of it owne accord, but becauſe it is moued with the leaſt impulſion of the outward aire and is ſtirred with locall motion; for whẽ the outward aire mooueth the membrane of the Drum, the internall aire is alſo mooued, that it may receiue a forme like to the forme of the ſound which is made. Immooueable How it is mouable.

It is *Plentifull*, for plenty is required for the full reception of the ſound; ſome ſay that it may be able to receiue many ſounds offered vnto it at the ſame time, but *Placentinus* ſaith it doth not receiue many ſounds becauſe of the multiplicity of the partes thereof, becauſe each ſound is receiued by euery little particle thereof. Plentifull.

It is *ſeparated from the externall aire* by the interpoſition of the membrane of the Tympane leaſt the inſtrument of hearing ſhould be offended. For if the externall ayre ſhoulde haue gotten into the inward aire; if it had bene either too cold or too hot it would haue violated the auditory Nerue, and by continuity the After-braine alſo and the Braine it ſelfe. Moreouer, if the externall aire ſhould haue bene imediately ioyned and commixed with the internall, ſeeing the externall is in perpetuall motion, thicke, impure, oftentimes alſo ſmoakie and full of ſmall creatures, it could not haue bene auoyded but that the Hearing would thereby haue bene impaired if not periſhed; for the inbred aire alſo woulde haue become thicke, ſmoaky, and alſo filled with thoſe ſmall Animals. It would alſo haue ſomtimes happened in violent motions of the outward aire, that the in-bred aire and with it the Animal ſpirit muſt haue bene ſhouldred out of their proper place and the hole of hearing quite rammed vp. Furthermore, this benefite wee haue by the membrane that ſeparateth the externall from the implanted aire, that if a man be vnder water the water cannot pierce into his head or take away his ſenſe of hearing, as thoſe Diuers find by experience, who for Fiſh or Pearle or any ſuch like occaſion do vſe to Diue into the bottome of the water. Separated from the outward aire.

Neyther is this implanted aire of the ſame nature that the outward aire is of, but hath only

The Nature of the implanted Aire.

onely a similitude therewith, which we may gather out of these words of *Galen*. *Neyther is euery Instrument of sense changed, altered or affected by euery sensible obiect: but that which is bright and light some is altred by colours, that which is aiery by sounds, that which is vaporous by odours, and in a word that which is like is familiar to his like.*

Like the Animall Spirite.

Wherefore we esteeme the nature of this aire to bee the same with the Animal spirite which also is aiery, and that there is the same maner of the conseruation and refection of the one and of the other. For this implanted aire is successiuely generated and againe dissipated, as the Animall spirit is continually spent in the Animall actions, and againe euery day regenerated. In like manner this aire that is bred in the eare is (at least a parte of it)

How nourished and restored.

continually dissipated and generated againe; for if it should altogether bee exhausted or spent we should vtterly loose our hearing. Now it is strengthned and hath his refection from the aire which we draw in by our nosethrils and through our mouthes, especially by that which entreth at the mouth, for there is a patent and open passage thorough the Canale which we haue before spoken of out of the mouth into the Eares, by which passage also we saide before that the eares were purged.

Simplicius. *Coyter.*

Simplicius the Philosopher hath deliuered, not that this aire is like the animal spirit, but that it is a thing Animated or hauing a life of it owne, wherby it subsisteth. *Coiter* calleth it a part of the Soul, *Archangelus* conceiueth that it is norished by blood, whose opinion we will heere set downe, that those that list may iudge of it.

A passage out of *Archangelus.*

The aiery bodie (saith he) is nourished by blood brought by the Veines, and that *per Diadosin* that is by Transumption, as the Cristalline humour of the eye is nourished by the glassie humour, by this *Diadosis* or transumption. For there redoundeth out of the glassy humor as much as is sufficient for the nourishment of the Cristalline, like as the glassy humor transumeth from the Membrane called *Aranea* or the *Cobweb* an Aliment accommodated and proportionable to it selfe. And this commeth to passe after this manner. In the Coate called *Aranea* or the *Cobweb* there are Veines by whose bloud it is nourished. After the Cobweb is satisfied, that which redoundeth or is superfluous is transumed by the Glassy humor: when the Glassy humour is satisfied with norishment, that which remaineth is transumed by the Cristalline humor as a fit nourishment for it, so that the Cristalline is nourished by an Aliment, prepared by the vitrious humor, & the vitrious or glassy humor is nourished by an aliment prepared by the Cobweb, to wit,

What *Diadosis* or transumption is.

How the Aire is nourished.

either of the others superfluities or leauings.

The same happeneth in the aiery iustruments of Hearing. For the Membrane that inuesteth it receiueth Veines and is nourished with their blood: that which aboundeth beside the nourishment of the Membrane, being now far altred from the nature of blood is attracted and transumed by that aierie body into his proper nourishment. But that this instrument of Hearing might haue not onelie venall nourishment but Arteriall life also, and with it al the parts that are subordinate and ministering to it; there are certain Arteries which are deriued into the structure of the organ of Hearing. Thus far *Archan.*

The vse of this Aire.

Concerning the vse of this implanted aire our Authors are full of diuersity. *Aristotle* in the 10. chapter of his second Booke *De partibus Animalium* and in the second chapter of his fift Booke *De Generatione Animalium* cals it *audiendi sensorium*, the verie Sense of Hearing it selfe. And truly the Ancients haue all deliuered that it is the chiefe and principall Organ of Hearing, and from hence it was that *Aristotle* saide that the Nature of Hearing was aiery.

Diuers opinions.

Aristotle

Mundinus.

Mundinus saith, there is an audible spirit in the cauity of the Stony-bone which is the instrument of Hearing.

Carpus.

Carpus thus. The implanted aire receyueth the species or formes which are brought to the Sense of Hearing.

Varolius. *Coiter.* *Archangelus.*

Varolius. The included aiery spirit is the proper instrument of Hearing.

Coiter. This aire is the first and principall organ of Hearing, yea a part of the Soule.

Archangelus. It is the most principall instrument of Hearing, which the Faculty vseth in the perception of sounds and voices, and in iudging of them.

Aquapendens.

Aquapendens. The office of this aire is to receiue outward and externall sounds, & so it is the principall author of Hearing.

Placentinus.

Placentinus. It is the matter which receyueth the sound, the *Medium* where-through it is transported. For after it hath receyued a sound it doth not conceyue it or iudge of it as being a thing inanimated, now no action of the soul can be performd by that which is not animated.

Laurentius

Laurentius. This Aire is exceeding neceſſary to the Senſe of Hearing, without which I can ſcarcely conceiue how we ſhould heare at all; but that it is the principal organ of Hearing I could neuer bee perſwaded, eſpecially becauſe it is not Animated, but rather I beleeue it to be an internall *Medium*. *Laurentius.*

Finally, our Authour *Bauhine* ſetteth downe the vſe of it in theſe tearmes. *Bauhine.*

This Aire the faculty of Hearing vſeth as an internal *Mediū* for the ſuſception and tranſvection or tranſportation of Soundes and Voyces to the Auditorie nerue, by it to bee diſcerned, like as in all the inſtruments of the other Senſes there is required a double *Medium*, the one outward the other inward. Inward, as in the Sight the watery humour, in the Taſte the ſpittle, in the Smell the ſpongie bones, in the Touch the skinne is the internall *Medium*, (although I know *Laurentius* would haue it the Cuticle) in which the formes or *Ideas* of things are ſeparated from the things themſelues, and ſo naked are tranſported vnto the firſt *Senſator*. An inward & an outward *Medium.*

In like manner the implanted ayre is gathered in the inward eare, to receiue the abſtracted formes of the Sounds, and to tranſport them or conuey them vnto the Senſe.

Againe, as in all the inſtruments of the Sences the internall *Medium* is diſtinct, and a differing thing from the principall Organ to which the action particularly belongeth; as in the Organ of Sight the waterie humor is thought to be the internall *Medium*, but the chryſtaline the principall part receiuing the repreſentations, but not iudging of them: ſo in the Hearing the internall *Medium* is this implanted Aire; but the principall part is the Auditorie nerue, which yet doth not iudge of the *Idea*, but conducteth it to the braine, that is to the firſt *Senſator*. That it is not the chiefe organ of hearing.

CHAP. XXV. *Of the manner of Hearing and of the Nature of Soundes.*

COnſidering that to intreate of the manner of Hearing belongeth rather to a Phyloſopher then to Anatomiſts, wee will be but briefe herein, yet ſomthing we thinke good to ſay becauſe the ſtructure of the eare was for the moſt part vnknowne to the Ancients.

The Eare is the inſtrument of Hearing, and the action of the Eare is the Senſe of Hearing; vnto this Senſe there are three thinges required: an Obiect, a *Medium* and an Inſtrument. The Obiect is that which is audible, that is, all Sounds. A Sound is a quality yſſuing out of the Aire (*Coiter* addeth, or the Water) beaten by ſudden and forcible colliſion or concurrence of hard and ſolid bodies, and thoſe ſmooth, concauous and large. This definition we will labot to explaine in this following diſcourſe. The *Medium* is eyther Externall or Internall. The Externall *Medium* according to *Ariſtotle* is Ayre or Water, but in water the Sound is but dull, as a man may perceiue when his head is vnder water: yet they ſay that Fiſhes can heare in the water very well, as they can aſſure vs that vſe in the night time to fiſh for Mullets. And although the water going into the water doe make a Sound; yet this Sound is made *in* the Aire and by the interpoſition therof, though it be made *by* the water. Three things required to Senſation. Obiect, Definition of a Sound. *Medium.*

The Internall *Medium* is the implanted Ayre concluded within the dennes or cauities of the Eares. The Inſtrument although we may ſay it is the whole inward eare furniſhed with his cauities and other particles aboue expreſſed, and although that generally the Philoſophers and Phyſitians doe determine that the inbred Ayre is the eſpeciall and proper Organ of Hearing; becauſe as in the Eie the Chryſtaline receiueth the Obiect, that is, the Light: ſo this in-bred ayre receiueth the Sound. Yet we are of opinion that not this ayre but the auditorie nerue is the principall inſtrument. For wee thinke with *Galen*, that not onely the alteration or Reception which is made by the in-bred ayre is the Senſe of Hearing, but alſo the dignotion or iudgement of that alteration. VVherefore Soundes and Voyces are transferred by this ayre to the Auditory nerue as vnto the ſubſtance that is apprehenſiue, and from thence to the common Senſe where they are exquiſitly iudged off. For if they muſt bee knowne and perceiued, then muſt they touch ſome ſubſtance indued with Senſe, becauſe all action is by contaction. Now the Senſatiue faculty is not tranſported out of the bodie, and therefore it was neceſſary that the Sound ſhould apply it ſelfe to the Eare. 3. Inſtrument.

The Sound is generated of hard bodies mutually ſtriking one another, as of the Efficient cauſe, (for ſoft bodies doe eaſily yeeld, not reſiſting the force that is offered vnto them) and How ſound is made.

and is receiued in the ayre as in his matter: this Aire accompanieth the Sound, and carryeth it as it were on his wings; for as the ayre is mooued so also is the Sound carried as wee may perceiue by a ring of Belles farre off from vs: for when the winde bloweth towards vs we shall heare them very lowd: again when the ayre is whiffed another way, the sound also of the bels wil be taken from vs. So also when two hard bodyes are smitten the one against the other, we see the purcussion before we heare the sound, for we do not heare the sound before the ayre that was moued do bring the sound with it to our eares, neither is that motion made in a moment but in time, and is carryed swifter or slower as the percussion of of the resisting bodyes was more or lesse vehement and quicke; (for this the Phylosopher requireth in sounds) and consequently the repercusion or repulse of the ayre. So wee see in a Drumme if the skin or Vellam be moist and laxe, either they will not sound at all, or they make but a dull noyse.

How the sound attaineth to the Eare. A fit comparison.

The Aer being affected with the quality of the sound driueth & altereth that ayre that is next it, and so by succession till the alterations come to the Ayre that is next to the outward Eare: euen as when a stone is cast into the water it stirreth vp circles which driue one the other till the water moueagainst the brinke, or if the water bee broade doe of it owne accord determine. In like manner by the percusion of the Ayre there are generated certaine circles which mooue one another till by succession they come to the Organ of hearing: which continuation of the Ayre thus beaten *Auicen* and the antient Anatomists call *vndam vocalem*, the vocall waue.

Vnda vocalis.

But if the stone be great and violently throwne into the water, so that it drieth the circles vehemently to the brimme of the pond, then will those circles be repelled againe and so runne doubled and hudling to the first circles. In like manner if we hallow or speake alowde against any arched place, or against a wood or a mountaine, the voyce will bee doubled and an eccho will answer vs.

What Ayre is fittest to receiue a sound

But all ayre doth not alike receiue a sound. For a pure thin and cleere ayre, which is vehemently and suddainly strucken by two hard bodyes whose superficies is broad, will sooner receiue the sound, and represent it more smartly then if the Ayre or the bodyes bee not so prepared. A Needle strucke against a Needle will not make a sound though they bee hard bodyes, because their superficies is narrow and not broad, and so in the rest. But aboue all that Ayre which is contained in a concauous or hollow place, doth best receiue the species of soundes; because in the reflexion there are many percussions besides the first; for the reuerberation of the Ayre maketh much for the increasing of the sound, which we may see in dens, caues, woods, hollow mountaines, wels, and such like; which will not only returne againe the sounds that they receiue, but sometimes also the very articulated words. And thus much concerning the nature and generation of sounds, which is a meere Phylosophicall disquisition, and therefore we passe it ouer more briefly. Now let vs come to shew how the outward Ayre that is beaten, is communicated with the implanted Ayre and the internall parts.

Diuers opinions of the manner of hearing.

But before we descend to this it shall not be amisse to let you take a view of the diuers opinions as well of the Antients as of the Moderne writers, concerning the manner how hearing is made, for vpon that very point we now are.

1. *Empedocles.*

The first is that of *Empedocles*, who thought that this sense of hearing is made because the Ayre offereth a kind of violence to the inward part of the Eare, for because the inward Eare is intorted like a winkle-shell, and hangeth as a bell in thee steeple of the body, it easily perceiueth all appulsions of the Ayre.

2. *Alcmeon.*

The second is that of *Alcmeon*, who thought that wee therefore heare because our Eares are within empty, for all emptie things doe resound if the sound get into them.

3. *Diogenes.*

The third is that of *Diogenes*, who saith, that in the head there is an Ayre which is smitten by the voyce and so mooued: against whom *Hippocrates* writeth in his booke *de carnibus*, where he saith, that there are some Authours of Naturall Phylosophy, who affirme that the Braine yeeldeth a sound, which cannot be. For the braine it selfe is moist, now no moist thing will resound, but that onely which is drie.

4 *Hippocrates.*

The fourth is the opinion of *Hippocrates* in his booke *de locis in homine*. First of all saith he, the eare is perforated, and in that part we heare, yet the emptie places about the eares doe heare nothing but a confused noyse, but that which entereth through the membranes into the braine, that is distinctly heard; where there is a perforation through the membrane

membrane which inuesteth the Braine. And in his booke *de carnibus*, we heare because the holes of our Eares reach vnto the dry and stony bone to which is added a canale or fistulous cauity, against which hard bone the sounds do beate, and the hollow bone because of his hardnesse yeelds a reasonance. Now in the hole of Hearing neere that hard bone, there is a thin Filme like a Cobweb the driest of all the Membranes of the body: but that which is the driest is fittest to conceiue or receiue a sound as may be prooued by manie arguments. When this Membrane therefore yeeldes the greatest resonance then wee heare best.

The fift is *Platoes* opinion. The aire that is implanted in the eare is beaten, that pulsation is transmitted into the principall seate of the soule and so we heare. 5. *Plato.*

The sixt is *Aristotles*. We heare (saith he) when the aire is mooued by two solid bodies, that which is beaten hath a plaine superficies that from thence the aire might result; the concussion of these two bodyes must be vehement, that the aire between them may not diffuse it selfe, but bee apprehended and smitten before his dissipation, for so onely the sound resulteth and filleth the aire by continuation euen to the eare. Now in the organ of Hearing there is a certaine implanted Aire. Hence it commeth that when the externall aire is mooued the internall receyueth therefrom a motion and agitation (which otherwise of it selfe is immooouable) so as it exactly perceyueth al the differences of the motion of the externall aire. Thus is the Hearing begunne and perfected in the Ayre. 6. *Aristotle.*

Seauenthly, *Galen* in the sixt chapter of his eight Booke *De vsu partium*. It was necessarie (saith he) that from the Braine a certaine surcle should be propagated downwarde to the eares, which might receiue the sensible obiect comming from without, whether it were a voice or a sound made by the percussion of the aire; for the motion that is caused by such a percussion diffuseth it selfe like a storme of winde or raine, or like a waue of the Sea till it ascend vnto the Braine. 7. *Galen.*

Thus far the Ancients, who most of them, if not all, were ignorant or at least much to seeke in the exact Anatomy of the Eye. Among the later writers *Vesalius* and his adherents haue it thus. 8. *Vesalius.*

A Nerue of the fift coniugation proceedeth through a torted and writhen passage, and extendeth it selfe into a Membrane where-with the hoale of the eare is stopped, which Membrane being thin, dry, and well stretched & beaten by the outward aire maketh a sound, being assisted by the hardnes of the bone and his turning gyrations much like the shell of a Snaile or Periwinkle.

Columbus. So also we heare by the help of a Nerue of the fift coniugation, which at the middle of the Labyrinth becommeth thicker, but yet maketh not the Membrane.

Messa saith, that the sound is made by the motion of the small bones, and thence we heare. 9. *Messa.*

Volcherus Coiter. The outwarde Aire affected with the quality of the founde runneth vpon the Membrane or Head of the Drumme, which when it is beaten mooueth the small bones that are tyed to it. The bones strike the Nerue that runnes ouerthwart the Membrane. The same Nerue makes a repercussion vpon the Membrane, whence it is that the ayre included receyueth the alteration and the sound. The Sounds without any disturbance are carried through the contorted Meanders of the Eares to the Auditory Nerue, which receyueth the Image of the noise, and presenteth it to the principall Sensator. 10. *Coiter*

Laurentius hath almost the very same in substance. The outward aer (sayth he) being stricken by hard and solid bodies and affected with the quality of the sound, altreth the aire that is next vnto it, till by a continuation it come to the eares, where it first encountreth with the Membrane: the Membrane being strucken mooueth the three little bones and transmitteth in a moment the liuely Charracter of the sound, which Character is receyued by the implanted aire, and through the windows it sendeth it through these crooked and winding Labyrinths into the Snaile shel, from whence it arriueth at the auditory Nerue, and from thence is conueyghed to the common Sense as vnto an equal iudge or Censor. 11. *Laurentius.*

Archangelus hath it on this manner as neere as I can vnderstande him. The thing that maketh the sound sealeth or stampeth in the ayre the species or forme of the sound, and withall driueth it on vnto the Instrument of hearing which is also aiery that it might better 11. *Archangelus*

ter receiue thoſe ſpecies, and muſt likewiſe be mooued; wherefore the hole of the Eare ſtanding alwayes open (and in his inſide ſupporting the ſtretched membrane of the Tympane, behinde which the aiery inſtrument of Hearing is concluded or ſhut vp, and to which the Anuile cleaueth) when the outwarde aire attaineth to that membrane the Hammer beateth vppon the Anuile, and ſo it commeth to paſſe neceſſarily that the Inſtrument of Hearing (by which he vnderſtandeth the implanted Ayre) it mooued with the ſame motion that the outward Aire is moued, whence it is that altogether the ſame ſpecies or ſimilitude of ſound mooueth the Faculty of hearing, which is brought thither by the outward aire. Nowe the Nerues of Hearing do determine into the ſame place where this aerie inſtrument of Hearing is concluded, and a membrane made of the amplification of theſe Nerues encompaſſeth that aery bodie, as the Opticke Nerues doe ariue at the Criſtalline humour. And as the Opticke Nerues do conuay vpon the wings as it were of the Animall ſpirit from the place of the Common ſenſe the *Viſiue* Faculty to the Criſtalline humor: ſo theſe Nerues from the ſame Common ſenſe doe tranſport the Faculty of Hearing to the principal organ of Hearing, that there might be a perception made of audible things. And ſo the Hearing when it hath apprehended the ſounde of an audible thing carrieth it to the Soule, and then the Reaſon or the intellectuall or ſenſatiue Soule comprehendeth and taketh knowledge of that which maketh the ſound to be a Bell or a Drum, or any other thing.

13. *Bauhine.* Finally, *Bauhine* my Authour (I call him ſo often my authour to ſtoppe their mouths who would think that I ſhould arragate too much to my ſelfe if I ſhoulde not acknowledge him from whom I haue taken moſt of this Hiſtory) expreſſeth it on this manner. The outward Aire is an external *Medium* which being driuen and moued by the mutual percuſsion of two hard bodies and affected with the qualitie of the ſound, carryeth the ſound which reſulteth from that percuſsion vnto the Eare. The ſound paſſeth through the hole of hearing which is alwayes open vnto the Membrane of the Tympane which it mooueth.

That Membrane being mooued, the implanted or in-bred aire is alſo moued and receiueth the ſound, or at leaſt his Caracter or impreſsion, and tranſporteth it out of the firſt cauity of the ſtony-bone thorough the hole of the Stirrop and the *Ouall window* to the other two cauities which we called the *Labyrinth* and the *Snayle-ſhel*. From thence it is conueighed to the auditorie Nerue and to the originall thereof, that is the Afterbrain and ſo to the common ſenſe as vnto a Iudge that is able to determine of the differences of ſounds.

And becauſe the Auditory Nerues are ioyned in the *Bridge* of the After-brain from whence they proceed, therefore all ſounds are apprehended in one comprehenſion, not in two though there be two eares, that is, two organes of Hearing. But leaſt the Membrane before mentioned ſhould be driuen too much inward by the violence of the outward aire when it is violently beaten, Nature prouided three ſmall bones and Muſcles as we haue ſhewed before to preuent that inconuenience.

The vſe of the Senſe of Hearing according to *Ariſtotle* in his Booke *De ſenſu & ſenſili* is to acquire or get knowledge and wiſedome. For ſpeech being an audible thing is the verie *Cauſe* of Learning. Againe by the Hearing things are ſignifyed to our ſelues, as by our voice and tongues we are able to ſignify any thing to another, as *Ariſtotle* hath well obſerued in the end of his third booke *De Anima*.

The vſe of the Hearing *Ariſtotle.*

A deprecatiõ. And ſo much ſhall haue beene ſufficient to haue ſpoken concerning the Senſe of Hearing, wherein I finde that I haue great cauſe to entreate my Reader fauourablie to reade ouer this Diſcourſe, and to pardon me if in ſome things I haue not ſo fully ſatisfied him; for there are ſome paſſages in my Author, wherein I haue bene intangled, partly by the difficultie of the matter, partly by the fault of the Printer, for in ſuch a caſe as this the leaſt error may prooue a ſufficient *remora* or obſtacle to interrupt the courſe of a Diſcourſe, but as neere as I could I haue followed their words, at leaſt their meaning, if they vnderſtood themſelues, as of ſome of them I make much doubt.

CHAP

CHAP. XXVI. *Of the Nose which is the instrument of Smelling.*

HAuing absolued the Historie of those many particles which belong vnto the sense of hearing we will now come to the third outward sense which is the Smelling. As therefore wee sayd in the Eare that there was an outward Eare and an inward Eare, so must we also diuide the Nose into an outward and inward. The outward Nose carryeth with it, sayth *Laurentius*, a kind of beauty, yea of maiestie; and the *Egyptians* in their *Hyeroglyphicks* signified a wise and prudent man by a nose: and *Festus* calleth such wise men *Nasutos*, as if they were able to sent or smell the politicke stratagems of other men. Besides man, onely those creatures haue this outward Nose that haue foure feete and bring forth liuing ones, as for birds and serpents (saith *Aristotle* in the 16. chapter of of his second booke *de partibus Animalium*) & and those foure footed beasts that lay egges, they haue onely τρῆς τῶν μυκλυριῶν, holes of the Nose, which are not so compassed or formed that you may call them Noses; vnlesse it bee because they breathe and smell by them. As for those Creatures which doe not breathe, they haue no Nose or holes at all, but other instruments of this sence, some smell by their gills, some by their *fistula* or pipe or trunke, some otherwayes, as some of those wee call *Insecta*.

The outward vse. *Nasuti.* *Aristotle.*

This outward Nose is called ῥὶς by *Aristotle* in the 11. chapter of his first booke *de historis Animalium*, and in the 16. booke *de partibus Animalium*, as also by *Galen* in his booke *de olfactus instrumento*. The word seemeth to be deriued from ῥέω, because through the Nose the excrement and superfluities of the head doe fall away. Others call it μυκλὴρ, because of the mucous matter or phlegmaticke excrement which distilleth through it. If we should describe the Nose, we must say that it is a protuberating or strutting part of the face, making a way for the Ayre, for by it we receiue it in and auoyde it out againe: some say it is a defence for the instruments of smelling, when as indeed they are not contained in the Nose, but remaine within the skull. Yet we will not deny but that it is an assistant to them, for if the Nose were away we should not smell without all question.

The names. The reason of the figure.

It is scituated betwixt the Eyes, for the part whereby wee breathe ought to bee in the middest and before. Nature therefore placed it in the middest betweene three other senses, the Sight, the Hearing and the Tast, and in a straight line that the respiration might not be interrupted but passe freely to and fro.

And scituatiõ.

Moreouer it is placed saith *Cicero* in his second book *de natura Deorum*, aboue; because Odours flie vpward and therefore from aboue are more commodiously receiued. Add hereto it that standeth vs in good steed to smell our meats & drinks being so neere the mouth, which instinct Nature hath giuen also to bruite beasts, as we may see especially in Apes who first smell to a thing before they will eate it. In a man the chiefe vse of the position of the Nose is for beauty and elegancie.

The Basis of the Nose aboue is broade and groweth into a blunt end downeward, or rather, saith *Laurentius*, it beginneth with a sharpe point from the inward Angles or corners of the eyes, and endeth at the beginning of the lips.

It is diuided into an vpper part which is immoueable and bony, and a lower, which is moueable and gristly. The vpper part of the Nose called *Dorsum* or the barke is called in Greeke ῥινὸς ῥάχις the spine or ridge of the Nose. The lower part where it inlargeth it selfe, into the Nosthrils is called ἀκροκέφιον by *Ruffus* and *Pollux*: the foote of the Nose, and the vtmost roundnesse σφαῖριον the globe of the Nose or the tip as wee commonly speake,

The diuision of the nose.

Within it is diuided into two cauities by a hedge or partition which they call *περίνεα*. *nares* the Nosthrils, because in them the odors or odoriferous spirits or the Ayre doe *innare* or swimme continually; others call them μυκλῆρες of the mucous matter that issueth from them, others τῶν ῥινῶν τόροι, the holes of the Nose as *Galen* hath it in his booke *de instrumento Olfactus*.

And the names of the parts.

The vse of the diuision is, that the action of the smelling might be more perfect, for in al the parts of sense (excepting the Touch) the sense is bypartite, because of the two sides of the body, the right and the left.

The vse of the diuision.

In like manner saith the Phylosopher in the tenth chapter of his second booke *de partibus Anim.* the power of the Nosthrils is double or bipartite, but if they had bin dissenered or set aside as the eares they could not haue performed their office; because we smell euen

breathing, as also doe all other creatures which haue nostrils. Againe, by reason of this diuision one nosethrill remaines open when the other is obstructed, that thorough it wee might haue the benifit of Inspiration and Expiration, and when both of them are obstructed the mouth may be opened to supply their office, as we see often in our Patients whose noses are stopped with a cold, they sleepe with their mouths open, drawing and yeelding their breath thereby least the man should be strangled.

The diuision of each hole.

It is further to bee noted that the holes of both the nostrilles (which is but one in one nostrill) about the middle of the Nose are deuided into two parts, as *Galen* obserued in his Book *de Odoratus organo*. The one part runneth aboue the palate into the vtmost part of the mouth and throate; whence it is that oftentimes we see that if a man laugh when he is a drinking the drinke will come out at his nosethrils: and those Irrhines which we cast into the nose sometimes for medicine, will fall into the mouth if the nose be close shut. The other part of the hole of the Nose ascendeth to the spongy bone. Finally, the outward parts of the Nose which compasse the holes are called πτερύγια *alæ pinnæ*, The wings of the Nose.

The Nose consisteth of a Cuticle, a Skinne, Muscles, Bones, Gristles, and the inward Coate.

The skin.

The Skinne wherewith it is couered is thin, without any fatte that the quantity of the Nose might not exceed, which would haue beene a great deformity; but vnder the partition in the middle of the Nosethrilles there is a rising or prominent fleshy particle neare the top of the lippe, called by *Ruffus* and *Pollux* κίων *Columna* the Pillar, which in some men hangeth something outward; it is thicke and fungous so that it resembleth the *Cartilage* or Gristle, (from which notwithstanding we must learn to distinguish it) and in the compasse thereof stand many haires called properly *Vibrissi*, because when we twitch them out it maketh vs shake our heads and sneeze, which is called *capitis vibratio*. The vse of these haires is, that those small Animals that flye about in the ayre should not be drawne into the nose in our Inspiration, but hang in those hairy springes.

The haires.

The muscles

But because in deeper and sudden Inspirations and Expirations the motion of the nostrilles serueth to no smal purpose, therefore Nature made thē mouable, & because they were to be moued according to our will and good pleasure, there are certaine muscles inserted into them; some seruing for dilatation, others for constriction; the first open the nosethrils, the other shut them. Those that dilate the nosethrilles are foure; two small ones arising from the cheeke-bones, two others arise from the seame of the fore-head. There are also other foure which constringe the Nose, two arising from the rootes of the wings, the other two are hidden in the cauity of the nose, vnder the coate which compasseth it about; but of these we shall heare more particularly in the booke of Muscles.

CHAP. XXVII. *Of the Bones, Gristles, Vessells, Coate and vse of the Nose.*

The bones.

THE Bones which make the cauity of the Nosethrils are of two sortes: some may bee sayed to be proper to the Nose although they be bones of the vpper Iaw, others are common. The proper are three: two external and one internall, and these reach from the top but to the middle of the Nose, the rest is gristly.

The common Bones are one fixed at the vpper roote of the nose within called σπογγώδη, by *Hippocrates* and *Galen*, and neare it wee finde two other fungous & spongy bones which fill the vpper cauity of the nostrils made for the voyce and the Reception of odours, which are vnited by the bone *Cribri forme*, so that some thinke them to bee partes thereof: but of these in the History of the Bones.

The gristles.

The Gristles of the Nose are fiue: three are before tyed to the circumferences of the bones, and two make the wings, of which we shall intreat amongst the Gristles.

Vessels

The vessells of the Nose are veines from the Iugular veines, arteries from the sleepy arteries, and nerues from the third coniugation of the braine on either side one.

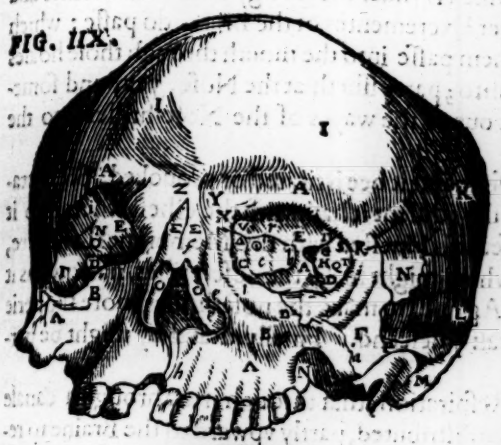
The coate or membrane.

The Coate (which *Galen* in his booke *de instrumento olfactus* calleth sometimes a coat sometimes a membrane, but a membrane most Anatomists call it) which compasseth the capacitie of the nostrils is, as *Vesalius* thinketh, an extension of a branch of the lesser roots of the third coniugation of sinewes. But *Columbus* and *Bauhine* take it to arise from the *Dura meninx*, and it is the common coat of the mouth, the palate, the toung, the *Larynx* or throttle,

Table xii. Fig. 8. sheweth the fore side of the Scull, as also the bones, the holes or perforations & the Sutures both of the scull and of the vpper Iaw: Figure 9. sheweth the Basis of the Scull, and many holes and Sutures there in.

TABVLA. XII.

FIG. IIX.



IX

AA. A hole in the forehead bone.
BB. The hole of the fourth bone of the vpper iawe, which is in the cheeke.
C. A hole of the second bone of the vpper Iawe in the inward angle of the eye.
DD. The fourth hole of the Wedge-bone in the outward side of the eye. EE. the first hole of the same bone
G. The second hole.
H. the 3. hole of the same bone in the seate of the eye.
II. The forehead bone.
K. The left bone of the *Synciput*.
L. The left bone of the temples.
M. the Mammillarie processe of the temples.
NN, the Wedge bone.
ΓΓΓ. the first bone of the vpper Iaw,
Δ, the second bone of the vpper iaw.
Θ. The third. ΛΛ, the fourth in the left eye.
ΞΞ, the fift bone of the vppet iaw in the Nose.
OO, the bridge or partition of the nosethrils.
P, the Suture in the yoake bone.
Q. A part of the 2. common suture from the first N to S.
R, S, T, V, X, Y, Z. The third common Suture drawn obliquely through the orbe of the eye.
a D, the first externall suture of the vpper Iawe in the Cheeke, and from thence through the eye to Q.
b, the third external suture of the vpper iaw from *b* to *c*.
c, the second external suture of the vpper iaw in the eie
e, the fourth externall suture reaching to Ξ.
f, the sixt externall suture of the vpper iaw in the middle of the Nose.
g, the second internall suture in the nose.
h, the seauenth externall suture of the vpper iaw.
i. A bastard suture of the vpper iaw at the eye.

The Ninth Figure.

A. The end of the Coronall Suture.
CC, the lower additaments of the Lambdall suture on either side. D, the fourth hole of the wedge bone in the outside of the orbe of the eye.
F, A part of the fourth proper Suture.
H, the great hole of the *occipitium* made for the spinall marrow. K, A part of the bone called *Synciput*.
LL, A part of the forhead bone. MM, the lower part of the nowle bone. N, A rift or cleft of the wedge bone which is common to the bones of the temple, drawn on the left side from *n* to *o*. OO, the wedge bone P. His foure processes marked 2, 3, 4, 5. A, R. the sixt hole of the wedgebone at the bottom of the throat. A. the seauenth hole of the same at R. Γ. the first bone of the vpper Iaw. S, Λ. the fourth. Π. The sixte, where the Cutter betwixt *c* and Π hath not well expressed the Suture. T T, the bones of the Temples on either side. V, the fourth hole of the bones of the temple made for the hearing. Ξ, the bridge or partition of the nose. X, the fyrst hole of the temple bone in his Basis. YY, the yoake bone. *aa*, the *anterior* part of the fourth proper Suture. *b*, the lower part of the Fist proper oblique Suture. *c*, the lower part of the bridge of the nose which is like a Coulter where 3 is placed. *d*. the vpper part of the second common Suture. *f*, the First externall Suture of the vpper iawe in the Cheeke. *g*, the first common Suture in the side of the brow. *h*, the cauity of the Temples whereto the lower Iaw is articulated. *ii*, the Appendix of the Temple bone called *Styloides*. *k*, the Mammillary processe of the same Temples. *ll*, the knub of the nowle bone. *mm*, the sixt proper oblique Suture of the scull. *nn*, the seauenth transuerse Suture. *op*, A Line beginning from the last named Suture which climbeth by the temples, and is more like a diuision then a line *qq*, the lower part of the second common Suture of the scul in the hollowneſſe of the nose. *r*, the line of the hole of hearing. *ſ*, *a*, the stony Bones. *tv*, the 5 externall transuerse suture of the vppet iaw. *Xy*, the seuenth externall right Suture. *α*, *β*, A Bastard Suture of the vpper iaw in the pallate. *γ*, the hole of the eare. *δ*, the Fist hole of the temples neere vnto his processe where Y should be blotted out. B, A hole of the nowle bone which is not alwayes found. E, the second hole of the nowle bone made for the sixt coniugatiō of the sinnewes, and for the Iugular veine and artery. H. the First hole of the *Occipitium*, or nowle bone for the passage of the marrow. 3, The third hole or the outgate of the seuenth coniugation. *κ*, *λ*, two holes of the nose. *μ ν*, two holes in the palat which is accounted the fourth of the wedge-bone. *ξ*. Fiue holes in the basis of the wedge-bone. *π*, the hole of the fourth Bone of the vpper iaw in the Pallate. Note that M, V. at the right side pointeth out the cauity which the yoke bone maketh for the passage of the temporall Muscles

throttle, the gullet and the stomacke. This Membrane although it compasse the whole circumference of the mouth and the parts conteyned in the chops, yet is it one and continual, and of one and the same substance, but not alwayes of a like thickenesse. For in the Nosethrilles it is thinner, but in that part which is vnder the spongy bones it is thicker and full of small holes, through which the thicker Excrementes of the Braine do passe; which excrements as they descend doe part of them passe into the mouth through those hoales which are made out of the nosethrils thereinto; part yssueth at the Nose, yea, and sometimes with violent hawking wee fetch part out of the wayes of the Nosethrilles into the mouth.

Why wee sneeze when our nose is tickled.

This Membrane is of exquisite Sense, so that if it bee irritated or prouoked, Sternutation or Sneezing will followe, because of the consent it hath with the Chest whereinto it insinuateth it selfe: but why were the nosethrils inuested with this Membrane? I answere, to hinder the growth of flesh in the nose which might make the nosethrilles narrow, as it happeneth in the disease called *Polypus*. Againe, to make the nosethrilles more slipperie that the mucous excrement might more easily descend. Finally, that they might be partakers of Sense.

The vses of the outwarde Nose.

The vse of the outward nose is first for Respiration, that through it as through a canale or pipe the aire might be conueyed in to be distributed, partly vpward to the Braine to recreate and refresh the Animall spirit, partly downwards to the Lungs and the heart to refrigerate and coole the same. This is the first and especial vse of the outward nose: for although we respire also by the mouth, yet was not the mouth created for Respiration, because if the holes of the spongye bones or the nosethrils be obstructed (so that when wee sleepe we draw in our breath by our mouthes) the tongue becomes rough and the mouth dry (sometimes also it growes bitter) that when we wake we can scarse swallow our spitle. Hence it is, that Nature prouided the nose like a couer to defend the holes that go out of the nosethrils into the mouth through which we breath when we are asleep & our mouths shut vppe.

That the mouth was not made to breath by.

The second vse of the outward nose is to serue the sense of Smelling. *Hippocrates de Carn.* saith. The moyst Braine smelleth the odours of dry things, drawing them together with the aire through gristly bodyes. For the nose leadeth the ayre, informed, as it were, with the formes of odours through the hole of the Spongie bone to the Mammillary processes as vnto the principall organs of smelling, from whence it is conueyed to the braine: for if a mans nose be cut off at the roote, either hee cannot smell at all, or at least but imperfectly.

Galen.

The third vse is, that through it the excrements of the Braine might distill, or by a vehement effliation be blowne out. And these two last vses *Galen* expresseth excellentlie in the sixt chapter of his eight Booke *de vsu partium* on this manner. *From within outwarde are the Excrements of the Braine deriued through the Nosethrilles. From without inwarde are the Obiects of the smelling Faculty transported this way. One Instrument serueth these two turnes of Nature; one of which is necessary for the preseruation of life, the other for our better Life.*

Finally, the Nose serueth to forme the voyce, and addeth a great beauty to the Face.

CHAP. XXVIII. *Of the Inward Nose and the manner of Smelling.*

THat the Nose is the Instrument of Smelling all men will confesse, but because it is compounded of many and diuers parts, it is a great question to which particle among all the rest the *Action of Smelling* is to bee attributed. Of these we haue already examined those parts which make the outward Nose, it remaineth therefore that we prosecute our Historie in the parts of the Inward Nose.

The inwarde nose made of two parts.

The Inward Nose therefore consisteth of two parts, the bone called *Ethmoeides* or rather the Spongy bone and the Mammillarie processes. The Spongy bone is situated partly in the toppe of the Nosethrils, partly within the Scul. It is a couering of the Mammillarie processes thrilled full of holes or rare and Spongye, through which perforations the ayre is immediately conueyed to the Braine for respiration, and vapors for the distinction of odours; that way also the whole sourse of the excrements is conducted.

The Spongye bone.

The Mammillary processes which make the other part of the inward nose do proceede out

out of the Braine and haue their habitation within the Scul aboue the cauity or bosome of the spongy bone. Of this spongy Bone we haue sayd somewhat already in the 6. Chapter of the 7. Booke, and shall speake afterward more at large; and concerning the *Mammillary* processes we haue inteated of them sufficiently in the 16. Chapter of the 7. Booke, whether we referre the Reader, and proceede to discouer vnto you the manner of Smelling. And because I would not haue you think that *Hippocrates* was ignorant from whence this Sense came and where it was accomplished, you shall giue mee leaue to relate vnto you a short passage or twaine out of his works. The first is in his Booke *de Carnibus*, where hee speaketh to this purpose.

2. passages out of *Hippocrates*.

The Braine hath in it a Faculty of Smelling though it be moyst, and draweth through gristly bodies which are drie, together with the ayre the odours of drie things. For the Braine reacheth euen vnto the cauity of the Nose, hauing no bone in his way but onely a soft gristle like a sponge, which you can call neither a Bone nor Flesh. If therefore the cauity of the Nostrils bee dry, then doth the braine better and more exquisitly perceiue the odours of dry bodies. For it cannot smell water because it is moyster then the braine, vnlesse it bee corrupted. In like manner when the Nostrils are moyst we cannot smell, because at such times the braine doeh not draw the Ayre into itselfe.

Againe in his Booke *de locis in Homine. There is no passage tending vnto the Nose* (hee meaneth the Sense of Smelling) *but a loose and spongy substance, and that is the reason why we heare further then wee smell, for if the Sent be far from the Sense it is dispersed before it attaine thereto.*

Galen more distinctly (as being better acquainted with Anatomy) on this manner in a particular discourse of this subiect.. *The Braine sendeth out two sprouts long and hollow, taking their originall from the forward ventricles and determining at that part of the Scull where the Nose beginneth, where are placed certaine Bones called Ossa Ethmoidea*, that is, *like a Syue or Seare.* But we returne to the manner of Smelling. *Galen.*

According to *Aristotle* there are three things required, to euery Sense; an Obiect, a *Medium* and an Instrument or Organ. 3. things required to sense

The Obiect here are odours or vapours of a firie Nature. The Obiect.

But what an odour is, is not so welknowne as what a Sound or a Light, or a Colour is: wherefore in men this Sense is the dullest of all the rest, as *Aristotle* sayeth in his Booke *de Sensu & sensili*, and many creatures Smell a great deale more exquisitly then we; we touch more exquisitly then any other creature, at least that Sence in vs is most perfect. Whence it is that a man receiueth no Smell without pleasure or discontentment, because the Instrument is not perfect.

The Sense of Smelling is the middle Sence, for there are Fiue Senses, two that woorke by contaction, as the Touch and the Taste; and two that apprehend their obiects by the interposition of an other, as Sight and Hearing. Smelling the middle sense.

Now because Odours are not so manifest (saith *Aristotle* in the 9. Chapter of his second Booke *de Anima*) as Sapours (for our Language vseth the worde Sauour promiscuously in both these Sences) therefore it is that the names of Odours are taken by a similitude from sapors, so that some odours are called sweete, as that of Saffron and Honny; others sharpe as Tyme and such like; there is also a sower Odour, an acute and a fatte. VVherefore *Galen* in the 22. Chapter of his 4. Booke *de simpli. medica.* teacheth vs that Odors do moue the Taste as sapors doe; for if our meates be corrupted the Taste is able to find the vnpleasing odour and we throw them away. Yea almost in euery thing the Smell and the Taste haue a mutuall consent; we say almost, because in those things that are most fragrant and sweete smelling as is a Rose, the Smelling and the Taste doe much differ. For the Smell is delighted with the Odour of the Rose, but the Sapor thereof disturbeth the Taste. But as the Hearing is audible and inaudible, the Sight visible and inuisible, so also the Smelling is odorable (for it is no treason to Coyne words) or inodorable. That is inodorable, either that hath not nor can haue any odor, or that which hath but a little odor, or that which hath an euill or offensiue odor, and so much of the Obiect. Whence odours haue their names, The consent betweene the smell & the taste.

The *Medium* by which wee Smell is the Aire or VVater. For those creatures which liue in the waters whether they haue bloud or no bloud, are yet apprehensiue of odours, as also those that liue in the Aire. For Fishes and Snayles and those we call *insecta*, do smel their nourishment a farre off, and approach thereupon vnto it, because of the Alimentarie *species* of the odour, as Bees will flock to Honny, and so in the like. The *medium* of the smell,

How a man smelleth.

But man neuer ſmelleth but when hee draweth in his breath, for if hee hould his breath, though you put odoriferous things into his Noſe he cannot ſmell thē; the reaſon is, becauſe the inſtrument of his Smell is not placed in the ſuperficies of the coat of his noſtrils, but farre within, to which there are certaine perforations that leade. Againe, in inſpiration the inſtruments themſelues are dilated, which if they were not dilated the ayre could not paſſe through the pores nor aſcend vnto the proceſſes and ſo vnto the ventricles of the Braine. Other creatures, euen thoſe that are without blood do ſmell, though they do not reſpire, and they ſmell becauſe they are able to receiue and *perceiue* odours.

That vnbloody creaturs do ſmell.

And that they do *perceiue* odours, it is manifeſt, becauſe they are ſtifled with thoſe odors, whereby men are alſo ſtifled. For, ſaith *Ariſtotle* in his booke *de ſenſu & ſenſili*, as men get a ſtuffing in their heads, yea are ſometimes ſuffocated with the ſteame of Charcoales, ſo many inſectile creatures are driuen away with the ſmell or vapour of Brimſtone or other Bituminous matter, becauſe they are annoyed, yea killed by them.

A difference of this inſtrument.

Hence it followeth that the inſtrument of ſmelling in men differeth from the inſtrument of ſmelling in ſuch creatures, as a mans eye differs from the eyes of thoſe creatures which haue hard eyes. For thoſe creatures that haue ſoft eyes haue alſo eye-lids to couer them, which lids, if they doe not moue and open they cannot ſee; but thoſe that haue hard eyes haue no lids at all, nor any thing proportionable thereto, but they ſee immediately that which is to be ſeene.

In like maner ſaith the Phyloſopher, in thoſe creatures which doe not reſpire the chiefe inſtrument or Organ of Smelling hath no couer at all no more then their eyes haue. But thoſe creatures which draw in ayre haue their organs of ſight and hearing couered; yet becauſe in their breathing their veines and paſſages are diſtended, the inſtrument is vncouered, or it may bee their breath remooueth the couering away, but when they doe not reſpire they cannot ſmell, which is all otherwiſe in thoſe creatures that doe not reſpire. Hence it is that thoſe creatures that doe reſpire cannot ſmell when they are vnder water, for they muſt reſpire when they ſmell but in the water they cannot reſpire.

Ariſtotles conceit of the couers refuted by *Galen*.

This conceit of *Ariſtotles* concerning the couers of the holes of the Noſe, *Galen* in his booke *de inſtrumento olfactus* refuteth. For, ſaith he, it is an vncertaine thing which cannot be demonſtrated nor made euident, that we ſhould aſſurdly beleeue it to be true: beſide, ſaith *Galen*, it is of no vſe.

But let vs grant that in the bottome of the Noſe there is a couer which is opened by inſpiration, that the way may be made open for the ayre and vapours to paſſe in; and that when the inſpiration is ended, it againe cloſeth: It muſt needs be that the motion of this couer (ſaith *Galen*) muſt be Animall, or Naturall or Violent.

That it is Animall or voluntary no man will ſay, becauſe there is no neede of a couer or value for Animall motion; beſide Animall motion followeth our wills, but this couer is neuer opened ſauing when we draw our breath. Againe, the inſtrument of Animall motion is a muſcle, but in the top of the noſe on the inſide there are no muſcles.

Neither is this motion Natural as is the motion of the valuesof the heart, becauſe the motion of the Heart is perpetuall and not at our command.

An inſtance out of *Galen*.

Violent we cannot ſay it is, for then (ſaith *Galen*) when the Ayre ruſheth forcibly in the couers ſhould be opened euen without attraction or drawing of our breath; but this we are able to diſproue. For put a man into a chamber fulfilled with ſome ſtrong odour, and moue the Ayre neuer ſo vehemently, or lead the ſmell into his noſthrils with a reede (for ſo doubtleſſe thoſe couers if there were any would bee reſerated) yet hee will not ſent the ſmell at all, vnleſſe he draw in his breath. Concerning this matter, he that deſireth further ſatisfaction, let him reade *Galen* diligently. We will proceede vnto the third thing required to ſenſation, which is the Inſtrument.

The inſtrument.

Concerning the inſtrument of Smelling we haue before related the opinion of *Hippocrates*, of *Ariſtotle* anſwered by *Galen*, and alſo of *Galen* himſelfe. But the truth is ſaith *Archangelus* that all the antients were ignorant of this Myſtery.

Amongſt the latter Anatomiſts *Varolius* hath wel deſcribed it, ſo hath our Authour *Bauhine*, you ſhall heare both their conceits.

Varolius.

Varolius hath it thus: Two neruous productions proceed out of the very middeſt of the Braine, wrought as it were out of the ſubſtance thereof; theſe productions ſhooting forward doe determine at the top of the noſtrils and make the chiefe inſtrument of Smelling, to which place when the odoriferous exhalations doe attaine, the inſtrument *perceiueth* the ſpecies of the odor without any matter and into this ſpecies is changed; the exha-

lation is diſperſed or extended through the ſubſtance of the Braine.

Bauhine hath it thus: As the Eye is the inſtrument of the Sight, and the Eare of hearing, both of them compounded of many particles: ſo the inſtrument of the Smell is the Noſe. But becauſe in euery ſenſe there is one principall part, it is a great queſtion which is here the principall inſtrument by which the faculty taketh knowledge of the proper obiects of this ſenſe. Some thinke is is the Noſe, becauſe if we ſhut our Noſe and draw in the breath through the Mouth we doe not ſmell at all, but if we drawe our breath through the Noſe, the odour preſently ſtriketh the ſenſe. But becauſe there are ſome creatures that ſmell without Noſes, it followeth that the noſe is not the principall Organ but helpeth the perfection of the ſenſe, and is an aſſiſtant onely to the principall organ. We muſt therefore finde out ſome other part, and that in the Noſe or neere vnto it.

Bauhine. The principal inſtrument. Not the Noſe

The Bone it cannot be, ſaith *Galen* in his booke *de inſtrumento olfactus*, becauſe bones are inſenſible euery way, much leſſe can they diſtinguiſh of ſmels. It is not the coate or membrane of the noſe that diſcerneth odours, for though you fill the noſe with odoriferous things, yet we do not ſmell before we draw our breath. Againe this coate is verie like that membrane that inueſteth the vtmoſt part of the heade, which membrane partaketh not of this ſenſe, and therefore not this coate of the noſe. It is not the coate of the Palate, of the Chops, or the Rough Arterie; for if you ſtop your noſethrils & draw your breth through your mouth you ſhall not ſmell at all or feele any ſenſe of an odor, neither about the Pallat, or the Chops, or the Rough Artery. Wherfore the noſe is the way, or the pathe or walke of odoriferous things, although to ſay truth it was ordained rather for Reſpiration, ſaith *Galen*, then to ſmel with.

Galen. Not the bone Not the mem brane of the noſe. Nor the palat

The bodie therefore that perceiueth or apprehendeth odours is placed higher, & that is either the Spongie bone or the Mammillarie proceſſes. Not the Spongye bone becauſe, as is ſaid, bones are inſenſible altogether. It remaineth therefore that it muſt be thoſe proceſſes which becauſe they are ſomewhat like the nipples of a Dugge are called *Mammillares*, which proceeding out of the baſis of the Braine are by the *Piamater* (ſaith *Archangelus*) ioyned to the braine and repoſed in the vpper part of the Spongye bone called alſo *Ethmoides* (for wee will confound them) and becauſe they are two, they are diſtinguiſhed or ſeparated by a production of the ſame bone carrying the Figure of a Spur-rowell.

Not the ſpongie bone But the Mammillarie proceſſes.

They are much of the nature of Nerues, as is before ſhewed in the 16. Chapter of the ſeuenth Book, and therefore are beſt able (ſaith *Laurentius*) to diſcerne of the qualities they receiue: yea (ſaith *Archangelus*) they ſeeme to haue their originall from Nerues of Smelling which do degenerate into them. For from the back part of the marrow of the Braine at the fourth Ventricle doth the Odoratorie Nerue ariſe vnder the Optickes, and pacing forwarde are thruſt into the Mammillary proceſſes betwixt the Braine end the Wedge-bone. And theſe Nerues of Smelling (ſaith he) were made as canales or pipes through which the Facultie of Smelling (reſiding in the Animal ſpirite drawne out of the fourth Ventricle) might be tranſported vnto the Mamillarie proceſſe or the organs of Smelling; as the Faculty of Seeing through the Opticke nerues is tranſported vnto the eyes. The originall of theſe Nerues was vnknowne to *Veſalius*, *Columbus* & the reſt, becauſe haplie they vſed to Diſſect onely putrid or ſtale heades. But wee returne vnto *Bauhine*.

Their nature. *Archangelus* conceite of Nerues of Smelling.

Theſe Mammilarie proceſſes (hauing a peculiar Nature, Figure and Compoſition of their own) are eſteemed to be the principall organs of ſmelling, eſpeciallie becauſe there is no part in the noſe which can ſo eaſily be altred by odours as theſe: for being ful of ſpirits they do ſoone receiue the ſpecies of odours. For whereas odours do conſiſt in a kinde of exhalation (which is manifeſt becauſe odoriferous things doe onely ſo farre foorth ſmell as they exhale; whence it is that in Summer the ſents of thinges are more freſh and fragrant then in Winter) and exhalations are naturally drie, it was fit that the organ of Smelling ſhould proceede from a moyſt principle, that by reaſon of the contrarietie betweene the Obiect and the Organ which is neceſſarie in al actions, the inſtrument might ſuffer and be mooued by the exhalation. And becauſe the exhalation when it was come vnto that place might better be dilated or extended, this inſtrument dooth not ariſe from the Spinall Marrow, nor from out of any part compaſſed or conſtrained within narrow limits, but of the verie middeſt of the Braine where they are wrought out of the ſubſtance therof, & thence produced forward determine in the top of the noſe &

Bauhine Odors conſiſt in exhalation

ſo

ſo become the Organs of Smelling.

A brieſe Collection of the manner of ſmelling

We conclude therefore that the Smell is made after this manner. The Aire altred with Odors or by an aierie exhalation of odorifferous thinges is receiued by the Noſe, which like a Chimney is broad below and narrow aboue; but becauſe the proper motion of the exhalation is but weake that it cannot make a ſufficient impreſsion; it is increaſed by traction. Wherefore when the mouth is ſhut and the Cheſt dilated (for vnleſſe the Cheſt be dilated we can ſmell nothing) the exhalation that is diſperſed through the aire is by inſpiration drawne into the noſethrils: and becauſe out of them there are two holes which go vnto the pallate the greateſt part of that aire ſo drawne in entreth into the Lungs but without any ſenſe of odours; the reſt aſcendeth vpward to the inſtrumets of Smelling, but it is altred in the ſpongie bones euen as in the cauities of the eares the auditorie aire is prepared. This aire thus altred in the Labyrinths of the ſpongie bones together with the ſpecies or forme of the odour paſſeth thorough the holes of the *Sinciput* into the *Mammillary proceſſes*, or by them it is receiued and ſo conueyed to the common Senſe which is in the Braine that it may iudge thereof. For the Brain is the common inſtrument of Senſation or the organ of all the ſenſes, or it is the inſtrument by which the *Senſatiue Soule* perceiueth all ſenſible qualities, yea diſtinguiſheth and iudgeth of them. And thus much of the vpper part of the Face, wherin three Senſes are ſituated, of which we haue intreated.

CHAP. XXIX. *Of the Parts of the Face which are betwixt the Noſe, the Eares and the Chinne.*

THE parts of the Face which are onely in men and vnder the eies betwen the noſe and the eares reach as farre as the Chin, the Ancients called in Greeke μῆλα, in Latine *Gena*, becauſe in them haires are generated. Wee call them the Cheeks. They are diuided into an vpper part & a lower. The vpper is next vnder the Eyes, a little riſing betweene the noſe and the Ears & for the moſt part is red, in which place *Plinie* ſuppoſeth that modeſty or ſhamefaſtnes hath her ſeate, becauſe that part bluſheth in thoſe that are modeſt. *Hippocrates* called it κυκλὸς προσώπου, the circle of the Face, and *Pollux* μῆλον the Apple of the Face, beecauſe in forme and colour it is not vnlike an apple, beſides their colour flouriſheth moſt in the Summer of our age.

The particular parts, with their names.

The lower part is looſer, and is all that which is without the cloſing of the two Iawes, reaching almoſt all along betweene the chin and the eyes: when your teeth are ſhut you may raiſe it vp with your finger on the inſide, or make it ſtrut when you fill your mouth with Aire, not ſuffering it to go into your Lungs or out of your mouth. This is called in Greeke γνάθος, in Latine *Bucca* the Puffe of the Cheeke: That part which is betwixte the noſethrils and the vpper lip is called *Myſtax*. The cauity which parteth the vpper lip in two which is an impreſsion therein like a valley, is called in Greeke φίλτρον, as it were *amiable or louely*.

Archangelus. The Lips are cald *Labra* by *Cicero*, by others *Labia a lambendo* of licking, for ſaith *Archangelus*, men lick with their lips though other creatures, as Dogs and Cats and Oxen licke with their tongues. They are two, one vpper another lower, and are nothing elſe but Muſculous extremities of the mouth. *Ariſtotle* in the 11. chapter of his firſt Book *de Hiſtoria Animalium* calleth them χείλεα, becauſe they occupy the verie mouth. *Homer* alſo calleth them χείλεα, and *Lycophron* in that prouerbe vſed I thinke in all Languages.

πολλὰ χειλεὺς χ' ὑπερδέξιων πολῶν
μέσσα κυλίνδει μοῖρα παμμίξωρ βροτῶν,

A prouerbe out of *Lycophron*.

Great Deſtinie twixt the Lippe and the ſippe,
Cauſeth ſtrange chances often to ſtippe.

The vtmoſt and prominent parts of the lippes are called προχείλεα, *prolabra* by *Ruffus*, and thoſe parts that meete and looke redder then the reſt becauſe of the affluence of bloode are called πρόχυμα by *Pollux* and *Ruffus*. The hole which the two lips make when they are diuided is called στόμα, *Os* the mouth. Finally, the lower part of the Face vnder the neather lip which groweth ſharp is called γένειον by *Xenophon*, by *Cicero mentum a memorando* becauſe it ſhould ſeeme there is ſome vſe of it when we deſire to remember any thing. No creature (ſaith *Pliny*) hath a chin but man, which if it be round (according to *Pytha-*

g-

γρας) is a signe of an effeminate minde. The doke or dimple in the middest of the chin and a great ornament too, is called *νύμφη* the Nymph; the very sharp poynt of the chinne, bearing out in the lower Iaw is called *ξυγανὸς*; the flesh vnder the Chinne is called *λιγχανία* in Latine *Buccula* we call it a double Chinne. To conclude, the hayres that breake out in the Cheekes, the Lippes and the Chinne make the Beard, of all which parts we might discourse at large out of our Authours, but that we hast to that which is more profitable.

CHAP. XXX. *Of the Mouth, Palate and Vuula.*

THat which is in Greeke called *στόμα*, in Latin *Os*, we call the *Mouth*, comprehending vnder that appellation not onely the Cleft which is made by the opening of the Lippes, but also all that voyde cauity which is betwixt the Lips and the rootes of the Choppes, which are called *Fauces*. It is situated in the fore and middle part of the Face, that the handes might equally reach the meate on either side vnto it. The mouth.

It is also immediatly vnder the Nostrils, that not onely the Sapors or Tastes of our meates might be offered to the Mouth; but the Sauours & Smels or Odours to the Nosethrils. For it is fit both the Sences should iudge of that we put into our bellies. The reason of the situation.

The parts of the mouth are of two sortes: some are those whereof the Mouth is made, others such as are contayned within the Mouth. The partes whereof the Mouth is made are of two sorts, some fleshy, others bony. The fleshy partes are the Lippes; the Muscles of the Puffe of the Cheekes, of the Lippes and of the lower Iaw. For on the forside the Mouth is compassed with the Lippes, as well to shut vp the Mouth when we would, as also the better to sup liquid things; on each side are the Puffes of the Cheek swelling out. These partes are couered with the Skinne hauing Fatte vnder it, which Skinne in the middest is slitte ouerthwart like the Eye-liddes to giue way for the reuiuing of Aliment. The parts of the mouth. The fleshy.

The Bones are the vpper and the neather Iawes, with the Teeth fixed into them both. The bones.

All these parts as also the whole inward capacity of the Mouth is compassed with a thick membrane which in the palate is somewhat rugous, spredeth ouer the Gummes, couereth the vpper part of the Lippes, and being reduplicated maketh the *Vuula*. The Pallate.

The chiefe vse of the mouth is double; first to giue way for the assumption of meates and drinkes, and that in the mouth they might bee Tasted. For the Taste is apprehensiue of that quality of the meat which is fit for our nourishment; wherefore in the very ingresse of the mouth is the Tonge placed which is the proper instrument of the Tast, that nothing may be admitted into the mouth which doth not first make his quality manifest by the contaction of the Tongue: againe to breake the Aliment and to shred and mingle it before it be swallowed, that it may go prepared into the stomacke. The chiefe vses of the mouth.

The second principall vse of the mouth is for Respiration, that when the Nose is stopped the Ayre may yet be transported, some of it vpward to the top of the nostrilles, some of it downward to the Longues, for the nourishment and expurgation of the vitall spirits: especially for the framing of the voice, for we speake out of our mouths.

The secundary or lesse principall vse of the mouth is, that thorough it by hauking wee might auoide the excrements of the head, by Coughing the excrements of the Chest and the Longues, and sometimes also by Vomiting those of the Stomacke. The secondary vses of the mouth.

The Muscles common to the Puffe of the Cheekes and the Lippes are foure, twoe on each side. The one called *Quadratus* or the square muscle, the other *Buccinator* or the Trumpeter; and these muscles beside the vses they haue in beastes do in men helpe the Speach, especially the Sounding of a Trumpet or winding of a Horne or Cornet. The common muscles.

The Lippes which couer the mouth are two; one aboue, another below, whose substance sayth *Galen* in his 4. Book *De Anatom. Administrat.* and the third chapter, are fleshy, fungous and moouable, and that after an vncouth manner: for the Skinne and the Muscles are throughout exactly mingled together, so that *Galen* in the 11. Book *de vsu partium* and the 15. chapter, calleth the conformation of their substance a *Musculous Skinne*, or a skinny Muscle. The lips.

And as without they are couered with the Skin, so on the inside they are inuested with a membrade common to the stomacke and the mouth: whence it is that in those that are about to vomit the lower lip is often seene to tremble. These Lippes all creatures haue to eat and drinke with, but men make farther vse of them to helpe their speach, to auoyde their spittle, and moreouer they defend the Teeth from the coldnesse of the ayre, and are a great

Table 7. Fig. 1. Sheweth the muſcles of the Forehead, the Eye-lids, and the Cheekes.
Figure 2. ſheweth the muſcles of the Noſe, Lips, the lower Iaw and of the bone Hyois.

FIG. I.

FIG. II.

A 1, 2, The muſcle of the forehead and the right fibres thereof.
B 1, 2, The temporall muſcle.
αβγ 2, His ſemicircular originall.
C E 1, the firſt muſcle of the Eye-lidde compaſſing the whole lid.
F D 1, the third muſcle of the wing of the noſe which endeth into the vpper lip.
G H 1, the muſcle of the vpper lip.
G 2, The place of the yoke bone without fleſh.
I 1, the broad Mouſe-muſcle ſtretched ouer the cheeks and all the lower parts.
ηζθ the circumſcription or circumference of this muſcle.
I 1, the yoke-bone.
I 2, The grinding muſcle or the ſecond muſcle of the Iaw.
The forward K in the ſecond figure ſheweth the higher griſtle of the noſe.
L 2, the wing of the noſe.
M 2, a muſcle forming the cheeks.
N 2, the muſcle of the lower lip.
O 2, A part of the fift muſcle of the lower iaw called *Digaſtricus*, that is, double bellied.
P 2, the bone *hyois* is ſet in this place,
Q R 2, The firſt muſcle of the bone *hyois* growing to the Rough artery,
S 2, the ſecond muſcle of the bone *hyois* vnder the chin
The lower T in the ſecond figure ſheweth the third muſcle of the bone *hyois* ſtrearched to the iaw. The vpper T in the ſecond figure ſheweth the inſertion of the ſeuenth muſcle of the head.
V V 2, two venters of the fourth muſcle of the bone *Hyois*.
The backward K (put in ſtead of χ) ſheweth the ſeuenth muſcle of the head and his inſertion at the vpper T,
κλ 2, The originall of the grinding muſcle from the yoke-bone,
μ 2 the inſertion of this muſcle into the lower iaw,
ρ 2 A ſmall nerue running to the forehead out of the orbe of the eyes, π 2, a nerue propagated to the face, ρσ 2, two beginnings of the ſeauenth muſcle of the head. τ 2, His inſertion into the *Mammillary* proceſſe. υ 2, The clauicle or the coller-bone. φ 2, A place where the veſſels attayning to the head and the nerues of the arme do paſſe through.

great beauty to the Face.

For the performance of all theſe offices they ſtoode in need of Muſcles, ſome of which are common with them and the Puffe of the Cheeke, of which we haue made mention before: others are proper to the Lips onely, and they are ſixe; two on either ſide belonging to the vpper Lip and one on either ſide belonging to the nether.

The proper muſcles of the Lips.

The Iawes.

The Iawes are two. The vpper which in men is immouable, and the lower which is moued voluntarily with a double kinde of motion, one ſimple another compound: the ſimple motions are ſixe, vpward, downward, to the right hand and to the left, forward and backeward.

The compound motion is made of that which is to the right hand and to the left, and that which is forward and backward: and by this motion the Iaw is *circumduced* or led about. It is mooued vpward by the muſcle called *Temporalis*; downward by *Digaſtricus*, to the right hand and the left by *Manſorius primus*: backeward by *Manſorius alter*: forward by the fift paire: of all which as alſo of the common Muſcles we ſhal intreate in the booke of Muſcles and of the Bones in the booke of Bones.

The parts contained in the mouth are diuers beſides the teeth and the bone *Hyois*, of which we ſhall intreate among the bones. Theſe are the Gums, the Palat, the *Vuula*, the Almonds, the Tongue, the Larynx or throtle, the Muſcles of theſe parts, and the beginning

ning of the Gullet.

The Gummes are made of fleſh, which *Auerrhoes* ſaith is glandulous, the *Græcians* call it γλον ἀπὸ τῆς εἱλεῖν which ſignifieth to inuolue: it is hard, ſaith *Bauhine*, and immoueable that ſo the teeth might be better faſtened in their ſockets, ſo hard the gums are that ſuch as haue loſt their teeth are able to breake their meate ſometimes with them.

The Palate.

The Palate is the vpper part of the mouth, wherefore the antients, as *Hippocrates*, and *Galen* from him call it ὑπερῶας *Ariſtotle* οὐρανος, as it were *Cælum oris*. The Latines call it *Palatum*, becauſe it is fenced in with teeth, as it were with Pales, as if one ſhould ſay *Paled in* [Tab. 13. fig. 4. *.] The extenſion of the Palate is from the backepart of the mouth to the teeth and is hollow like an Arch, but the roofe is not too high, hence we call it commonly the roofe of the mouth, but thoſe whoſe heads are acuminated or like a Sugar loafe haue high roofes or palates as *Hyppocrates* obſerued in the firſt ſection of the ſixth booke *Epidemion*. This is the ſoale or baſis of the Braine eſtabliſhed by the wedge bone, which therefore *Galen* calleth the bone of the palate, though ſaith he in his nineteenth chapter of his eleuenth booke *de vſu partium*, it ſcarce touch the palate.

Whereof framed.

It is made partly of bony ſubſtance and partly of fleſhy; the bone is hard and faſt, leſt it ſhold rot by the confluence of excrement vnto it, as we ſee it doth in the French diſeaſe. This bone is double on both ſides, for it is compounded of the fourth bone of the vpper iaw into which the teeth are faſtened, and the ſixth bone which maketh the backeward amplitude thereof.

The bone sof it

It is alſo diuided in the middeſt by a Suture, in the end whereof are two holes through which the braine is purged into the mouth, and ſo there becomes a great ſociety betweene the noſthrils and the palate. Through th. ſe holes when wee hold our mouths cloſe we may exſpire and inſpire, breath in and out, and when the wayes of the noſtrils are obſtructed, the excrements gathered together in the ventricles of the Braine are this way deriued into the mouth.

The holes of it.

But the backeward halfe of the palate whic endeth into the *Fauces* or chops, & is ſtretched out from one ſide to another, conſiſteth of a thick and glandulous fleſh.

The coate of the Palate.

It is inueſted with a thicke coate ariſing out of the *dura mater*, which hauing gotten out of the skull is enlarged, becommeth thicker and compaſſeth the whole mouth and palate or the inſide, yea it is common alſo with the gullet and the ſtomach, Hence cometh the great conſent betweene the Palate and ſtomach, for it was fit that the coate of the palate ſhould haue the ſẽſe of Taſting, that it might take the aſſay vnto the ſtomach. Wherefore the ſenſe of it is more exquiſite, as receiuing it into his back part certaine ſmall nerues of the fourth coniugation, which coniugation is alſo diſtributed vnto the palate.

This is alſo the cauſe why wee cannot euacuate the head with Maſticatorie Medicines, but the ſtomach alſo will bee euacuated by the palate: now the head is euacuated by the palate, becauſe from the head certaine hairy threds of veynes doe deſcend vntõ the palate.

Plinie.

This coate of the palate in ſome places is rugous and rugged, which *Plinie* calleth *Crenas*, that the meate might be better mittigated.

Why it is hollow.

It is alſo hollow or concauous, that the voyce might be better formed when the ayre is reuerberated; in this concauity alſo as in a boſome the ayre we draw in is warmed, that it ſhould not deſcend cold vnto the vitall parts to offend them.

The names of the *Vuula*.

The *Vuula* hath many names: It is cald *Gargareon*, or *Gargulio* by *Hippoc.* by *Ariſtotle* κίων, but the proper name is *Gargareon*; κίων & σταφυλὴ, that is *vuula*, are the names of it when it is ill affected. The name *Gargareon* is a made word of the ſound we make when we gargle, or elſe from Gargles which we vſe in the diſeaſes of this part. It is called alſo *Columella & pleſtrum*, It is a particle of the mouth or a certaine poceſſe ſaith *Ruffus*, hanging directly downeward (from the inward part of the palate [Tab. 13. fig. 4. E.] neare the holes of the noſthrils which looke into the backepart of the mouth) into the capacity of the mouth betweene the Almonds [F F] abone the ſlit of the larynx or throtle [E] as will eaſily appeare if a man open his mouth wide and preſſe his tongue downeward.

The ſubſtãce.

The ſubſtance of it is glandulous, red, and fungous hanging downe from the middeſt of the glandulous part of the palate. Some thinke it is made of the coate of the palate reduplicated at the end of the mouth and a little elongated, this was *Columbus* his conceyt,

The names as they are properly giuen.

If it be diſeaſed by a fall of humours it is no more called *Gargareon* but κίων and κιονὶς & ραφυλὴ and ἰμὰς and ἰμάντων.

For if it grow equally thicke from the Baſis to the ende, and fall lowe, become redde,

then

then it is called κίων, that is, a Piller; but if the vpper part be ſlender, & the lower part grow round and liuid or blackiſh, then is it called σταφυλὴ or the *Vuula*, becauſe it is like a Grape both in colour and in magnitude, the ſtalke being the vpper part. It is called alſo κιονὶς, and therefore *Galen* calleth them in whome it is ill affected κιονικοὶ.

The vſe of the *Vuula*. The vſe of it is to temperate and moderate the coldneſſe of the aire we breath in, that it fall not ſuddenly vppon the Longues, and ſo the bloud (ſayth *Aphrodiſæus*) become condenſed and thickned by the Inſpiration of cold ayre, whereby the motion of the Longues might be made ſlower; whence it would follow that vpon ſo great a contention in the motion, the veſſels might be broken and a conſumption follow.

Another. Another vſe of it is to moderate and Tune the voyce, for onely Men and a few Birdes haue it: hereuppon it is called *plectrum vocis* the quill of the Voyce. For hanging in the cauity of the Palate betwixt the *Larynx* and the cauity of the noſethrilles it maketh a repercuſsion of the ayre as it yſſueth out of the Throttle. Hence alſo it is that it helpeth pronounciation very much as *Columbus* ſayth; who alſo auoucheth that if it be eaten away by the French diſeaſe, or cutt off when it is inflamed, the voyce will neuer be ſhrill or cleere after.

Columbus.

Gainſaide by *Fallopius*. This *Fallopius* gaineſayeth vpon his owne manifould experience, and *Bauhine* telleth a Storie of a Marchant whoſe *Vuula* (for I know no other name for it in Engliſh) had beene ſome yeares ſince conſumed by a defluxion of ſharpe humours, who yet found no decay or falt in his ſpeach to follow vpon it, marry otherwiſe he grew *Tabid*, that is, into a conſumption. VVherefore, ſayth he, we conceiue that thoſe that haue their voyces impayred by the French diſeaſe, doe not onely looſe their *Vuulas*, but the Vlcers eate away a great part of that glandulous body which is betwixt the Bone and the coate of the Palate, or elſe the bone of the Palate and the membrane is perforated. The like conceit alſo hath *Fallopius*.

A third vſe. Some adde a third vſe of the *Vuula* to purge the Aire, for it licketh vp the duſt which otherwiſe together with the ayre woulde deſcend into the Longues. But *Veſalius* doeth not approue of this vſe, and hee rendereth this reaſon, becauſe other creatures that drawe their breathes nearer the earth (and ſo more in danger of duſt then men) haue not yet this *Vuula*.

Varolius his vſe of the *Vuula*. Finally (for I will not inſiſt vpon euery mans conceit) *Varolius* concerning the vſe of the *Vuula* expreſſeth himſelfe on ſuch a manner.

The *Vuula* receiueth the excrement of the braine conuayed vnto the Phlegmatick glandule through the Tunnell; this excrement it imparteth vnto of the Palat, the Tongue and other inſtruments of the Voice to moyſten them, that which is ouerplus is caſt out by ſpitting and hauking. For as in a Flute the Sound will not bee ſhrill and cleare vnleſſe it bee wet, ſo it is in the voyce of a man: and therefore Nature placed the *Vuula* which receiueth the moyſture of the braine directly ouer the ſlit of the Throttle or *Larynx*, that it together with the rough Artery might better be moyſtned.

CHAP. XXXI. *Of the end of the Mouth called Fauces or the Choppes, and their Glandules.*

The extent of the word. ALthough the word *Fauces* or the Choppes, doe among ſome Anaomiſtes, *Veſalius* and *Laurentius* eſpecially, ſignifie al the capacity of the mouth; yet properly it ſignifieth the backeward and lower part of the mouth, or that ſpace where the endes of the Gullet and the rough Artery doe meete, and may not be perceiued vnleſſe the mouth be wide opened and the Tongue depreſſed. [Table 13. figu. 4. betwixt F and I] The Grecians call it φάρυγξ. Yet this word φάρυγξ hath diuers ſignifications: ſometimes it is taken for that we call *Fauces* or the Chops, ſometimes for the *Larynx* or Throttle, becauſe they are neare together, ſometimes alſo for the whole rough Artery. *Ariſtotle* in diuers places giueth this name to the Gullet. *Philoxenus Erixius* ſayeth a notable Gourmandizer wiſhed his φάρυγξ (that is his Gullet) bigger then a Cranes. Some by this word vnderſtand all the glandulous bodies about the Choppes. But in *Hippocrates* where wee haue this worde φαρίγγες put by it ſelfe, it ſignifieth ſome diſeaſe of the Chops, as their roughneſſe, as in the fift Aphoriſme of the third Section, or their Inflamations, as in the 7. Section of the ſixt Booke *Epidæm.* and the firſt Aphoriſme. This place alſo is called ἰσθμὸς by *Galen*, and ἴσθμιον by *Hippocrates* by a Metaphor, becauſe of the narrowneſſe of the place: for *Iſthmus* ſignifieth properly a narrow tract of ground betwixt two Seas, and in the whole body there is no part ſo narrow

Why it is called *Iſthmus*.

and

and straight which conteineth so many instruments. For in these *Fauces* are contained, first the holes of the nosthrils descending through the palate into the mouth [Tab. 13. fig. 4. after E.] of which we haue spoken in the historie of the Nose; againe, the muscles of the *Fauces* or Chops, the bone *Hyois* vnder the roote of the tongue, the tong it selfe, the Larinx together with the *Epiglottis* and the beginning of the gullet; beside the muscles of these parts and some of the lower iaw. Add hereto certaine propagations of the nerues of the third, sixt and seuenth coniugations, the iugular veines, the sleepy Arteries, and certaine glandules of which wee will intreate in the next place because they are best exhibited in the thirteenth Table. What parts are contained therein.

There are three sorts of Glandules in the region of the Chops.

The first is vnder the roots of the Eares (which *Vesalius* accounteth for the third kind) of which we will speake in the eleuenth booke. The 2. are those they call *Tonsillæ* or the Almonds, of which we will intreate in this place. The third are those (*Vesalius* calleth them the first) which grow at the roote of the Larinx on the sides of the rough Artery, of which we shal make mention when we come to the Larinx, but discourse of in the 11. booke Three sorts of glandules neere this place.

The Almonds are commonly called *Tonsillæ* [Tab. 13. fig. 4. F.] *Celsus* calleth them simply Glandules. They are situated in both sides of the Mouth at the rootes of the tongue betwixt the holes of the nosthrils and the Larynx, or betweene the beginnings of the weazon and the gullet, on either side one, large, long, and compared to Almonds, and therefore they are commonly called *the Almonds of the throte*. The *Gracians* call them *Isthmia*, because they are seated in the *Isthmus* of which we spake euen now. For if you looke into the cauitie of the mouth when the lower iaw is remooued, you shall see the two holes of the nosthrils and the *Vuula* or *Gargareon*: the two holes like two seas, and the *Gagareon* like a narrow tract or necke of land running betweene them. By the same name of *Paristhmia* they vse also to call not onely a part of the *Fauces* or Chops, but also the inflammation thereof, yea the diseases of these glandules when they are inflamed, or when they swell or are reficcated when they hinder (saith *Paulus*) the free passage of the drinke or the breath. For their swellings seldome hinder the passage of the meate because being but lax or loose bodyes the weight of the meate beareth them downe before it, and by this we commonly distinguish betweene the inflammation of the Muscles of the Tongue, which we call an *Angina* or Squinsie, and the swelling of the Almonds, for in the Squinsie wee cannot swallow any thing without great difficultie, and the more solid thing the worse; in the swelling of the Almonds we can hardly draw our breath or take downe any liquour, but solid meate will goe downe much more easily. The almonds

The differēce betweene the swelling of the Almonds and the squinsie.

Sometimes also by the word *Paristhmia* is vnderstood the inflammation onely of the coate which we sayde was common to the Chops, the whole mouth and the stomach; sometimes the inflammation of those muscles which lie next vnder the saide coate, sometimes the inflammation of the bodyes which are within the *Fauces*. *Paristhmia.*

They be also called *antiadæ* by *Hippocrates* in his second booke *de morbis*, because they are placed in opposition one vnto another; but this name is not giuen onely to the Glandules but also to their disease, so saith *Hippocrates* in the place before quoted. It will not bee amisse to thrust your finger into your mouth and to beare downe the *Antiades*, that is, the Almonds when they are swelled. Yet some put a difference betweene *Antiades* & *Paristhmia*, for they say, that the Almonds themselues inflamed are called *Antiadæ*, and the inflamation of the parts about the Almonds *Paristhmia*. So saith *Celsus*, the *Gracians* call the Almonds which are hard after their inflammation *ἀντιάδας*. *Antiades.*

They are couered with the common coate of the mouth and the other parts of which we spake lately which is neruous and in many places perforated with large and ample holes, insomuch that some haue sayde it is fungous. These holes saith *Fallopius*, if the glandules be a little swelled, are wont to deceiue Chyrurgions, for they take them to bee Vlcers, whereas indeed there are no Vlcers at all; for when the glandules fall they become againe according to their wonted nature. They also receiue veines from the iugulars. Their substance is like that of the glandules, but more rare, spongy and fungous, and therefore *Hippocrates* in his fourth book *Epidemion* cals them *σπόγγοι* Sponges, because after the manner of Sponges they drinke vp humiditie, yet *Hippocrates* also calleth their tumors by the name of *σπόγγοι*. How couered

A good note for Chyrurgions.

The vse of these Almonds is saith *Hippocrates* in his booke *de Glandulis*, to receiue the moysture of the brayne: this moysture it conuerteth into spittle, whereby all the parts with- The vse of the Almonds.

in the mouth are moyſtned (the Tongue kept from drying, made more glib and nimble) euen the gullet and the weazon. It helpeth alſo the Senſe of Taſting, for we cannot Taſt without moyſture; like as in the ſtomacke there is no concoction or mittigation without boyling, whereof they haue experience whoſe Tongues are rough and dry.

CHAP. XXXII. *Of the Tongue and his Muſcles.*

The names.

THE Tongue is called in Greeke γλῶττα in Latin *Lingua*, of licking, or becauſe it is as it were tyed within the pale of the Teeth ſayeth *Varro*. It is a notable inſtrument both of the Taſte and of the Voyce; becauſe in the Mouth it is placed next vnder the Palate [Table 13. fig. 4. I] in the way, ſayth *Cicero* 2. *de Nat. Deorum*, which Nature prepared for the paſſage of meats and drinks. The Baſis of it reſteth vppon the bone *Hyois* aboue which it is mooued, and neare the *Epiglottis* it maketh an angle or corner, and from thence hangeth and walketh freely in the mouth.

The place.

It was fit (ſayeth *Galen* in the fift chapter of his 8. Booke *de vſu partium*) that it ſhould be placed neare the braine as are the reſt of the inſtruments of the Senſes, becauſe it is the principall inſtrument of the Taſte. Wherefore Nature for the Tongues ſake placed the Mouth in the Head that it might haue a den or caue or chamber to moue in, that it might bee a conuenient inſtrument both of the Taſte and of the Voice, as alſo might helpe the chewing and ſwallowing of the meat.

The figure.

The figure of the Tongue is not alike in all Creatures, in ſome it is *Tri-fanged* as in Serpents, in others *Bi-fanged* as in Lizards; ſome haue two Tongues as the Sea-Calfe. In Fiſhes it is faſtned all along, in Lions and Leopards it is rough and furrowed, but in man it is ſomewhat long, thicke at the roote for ſtrength, and broade that it might bee fit both for Taſte and Speach. In the end it becommeth by degrees ſharpe for quicker motion ſayeth *Galen* in the 10. chap. of the 11. book *de vſu partium*. *Archangelus* compareth it to a *Pyramis*.

The vpper and rough part called ὀπιγλωσσὶς is hollowed on either ſide, thoſe they call χηραμὸς and παράταξα.

It is ſoft, broade and looſe or at liberty that it may be conuayed, produced, dilated and diuerſly diſpoſed; for in thoſe that are tongue-tyed wee ſee a manifeſt defect of vtterance. We may alſo obſerue out of *Ariſtotle* in the 17. chapter of his ſecond Booke *de partibus Animalium*, that thoſe Birds which can bee taught to prattle haue broade Tongues aboue other birds: and the reaſon why bruite beaſtes cannot deuide or articulate their voyce is becauſe their Tongues are hard, thick and not at liberty.

The magnitude.

The magnitude of the Tongue is not all one in all creatures, but proportionable for the kinde whereof they are. Neither is the quantity of it all one in all men; but it is longer then broade, and broader then thicke, and alſo proportionable for the amplitude of the Mouth, ſayeth *Galen* in the tenth Chapter of his eleauenth booke *de vſu partium*, that it might reach into euery corner and nooke thereof, and not hinder the receiuing of meate. But it is faulty ſometimes in magnitude, ſometimes in the very ſubſtance together with his muſcles. For if it be bigge it filleth vp the ſpaces of the mouth and the Chops, and then it cannot mooue ſo deliuerly or nimbly as otherwiſe it would, and ſuch men are called *blæſi* and *balbutientes*, that is Liſpers and Stutters, eſpecially if (as it happeneth moſt what) it bee alſo too ſoft or moyſt. Hence it is that Infants and thoſe children that are moyſter then ordinary doe ſpeake ſlower then others, becauſe of the ſoftneſſe and looſenes of their Tongues and the muſcles thereof, till when their heate by their age encreaſing the ouer aboundant moyſture be conſumed. The Tongue alſo ſometimes is too ſhort when the *Bridle* thereof is not enough cut, ſo then it is hindered that it cannot apply it ſelfe one-nery ſide to the Mouth; or becauſe the muſcles being little it is mooued too ſwiftly and ſo implicateth or doubleth the ſpeach and maketh the words come hudling together.

Bleſi, Balbi.

What childrē ſpeak ſlowly.

The connexions of the tongue.

It is tyed to the *Larynx*, to the bone *Hyois* vpon which the rootes thereof reſteth as vpon a Baſis and by which it is ſupported, to the Choppes alſo, and on both ſides to the Almonds; below it is faſtned with a ligament.

Whereof cō-pounded.

The Tongue is compounded of a proper fleſh, a coate, nerues, veines, arteries, muſcles and a ligament.

The ligament

The ligament is [Table 14. fig. 3. II] very ſtrong, membranous and broade, and is vnder the middeſt of the body thereof.

The vſe of this ligament is manifould: for the ſolidity and ſtrength thereof lifteth vp the Tongue, and not onely ſo but auaileth much to lill it foorth. For were it not for this liga-

Table 14. *Figure* 1. *and* 2. *ſheweth the tongue cut from the bodie, and the Muſcles thereof. In the firſt the right ſide of it, & in the ſecond his Muſcles ſomewhat vncouered.*
Figure 3. *ſheweth the bodie of the Tongue diuided according to the length of it and his Ligament.*

FIG. II.

FIG. I.

AAA. The Tongue inueſted with a Coate common to the mouth.
BB. A portion of the coat compaſſing the mouth cut frō the mouth according to the ſides of the lower iaw.
C A part of the ſame coat cut from the inner part of the Palat together with the tongue.
D. The Muſcles caled *Baſi-Gloſſi*, according to *Veſalius* the firſt, but in our account the fourth, or the ſixt of the bone *Hyoïs* according to *Falopius*.
E. The Muſcles cald *Ceratogloſſi*, or the ſecond Muſcle according to *Veſalius*, and in our account the fifte.
F. The Muſcles called *Styloglossi* or the third Muſcle.
G. The Muſcles called *Myloglossi*, or the fourth Muſcle according to *Veſalius*.
H. The fleſh conſiſting of the Glādules, or the ninth Muſcle of the Tongue according to *Veſalius*.
II. The Ligament of the Tongue.
KK, LL. The Muſculous ſubſtance of the tongue, & the fibres thereof.

The Second Figure.

a 1. The *Shield-griſtle* Diſſected.
b 1. The *Epiglottis* or After-tongue.
c,c. The *Arytænoides* or the Ewre-griſtle.
1, 2. The *glottis* or ſmall clefte of the Throttle.
ee, 1. The internall Muſcle forming this cleft or the internall Shield-griſtle.
f. 2. The opening Muſcle or the latter *Crycoarythænoides*.
g. 2. The tranſuerſe Muſcle or the *Arytænoydes*.

ligament the Tongue would be too much gathered backward, neither when it is ſhot out of the mouth could it bee eaſily retracted or drawne in againe. Moreouer, if it were on euerie ſide free and looſe it had not beene ſo firmely eſtabliſhed and faſtened in his proper ſeate. This Ligament alſo receyueth the inſertion, ſaith *Veſalius*, of the proper Muſcles of the Tongue which otherwiſe would eaſily haue bene relaxed or looſened or elſe parted aſunder. At the end of this Ligament toward the tip of the tongue there groweth a little Chord which *Arantius* and *Lawrentius* call the *Bridle* of the Tongue. For a mans Tongue in new borne infants is faſtened euen vnto the end with a Tye which the Midwiues do vſe to teare with their Nailes, ſometimes it is faine to be cut, becauſe it is a hinderance to their ſpeech, yea to their ſucking, becauſe it cannot lappe it ſelfe ſo well about the nipple. The tongue therefore beeing naturally nimble and voluble leaſt that it ſhoulde bee alwayes importunately pratling, is reſtrayned by this Tye, as it were by a Bridle. Wherefore, by the helpe of the Ligament and the Bridle and of manie Muſcles working together and contracted towards their originall, the Tongue becommeth nar-

row and pointed, lifted vp and diuerſlie mooued, and withall reſtrained from mouing too farre on any hand.

The coate of the Tongue.

It is inueſted with a coate common to it with the Mouth, the Pallate, the Gullet and the Larynx [Tab. 14. fig. 1. AA. BB. C] leaſt the laxe and rare ſubſtance thereof ſhoulde part aſunder. This Coate is all verie fine and thin, that the ſapors might more eaſily pierce through it into the pulpe and ſubſtance of the tongue, into which coate as alſo into the fleſh certaine Nerues of exquiſite ſenſe are diſſeminated.

The ſubſtance of the tongue

The ſubſtance of it is ſoft, looſe, rare and like a Sponge that it might bee the ſooner moiſtened with the humour which carrieth the Sapor in it; and ſo fitter to diſcerne of the diuerſity of Taſtes, for of them it is the competent iudge. Hence it is, that in diſeaſes it is diuerſly affected, for as the humour is that it imbibeth ſo is the ſenſe of Taſting deprаued, as we may ſee in thoſe that are ſick of the yellow Iaundiſe or of Agues. The fleſh therefore of the Tongue is proper and peculiar to the Tongue, there being none ſuch in the whole bodie: toward the Baſis it commeth neerer to a Glandulous ſubſtance then to a Muſculous, becauſe it is much ſofter and looſer; yet hath it all manner of fibres, but thoſe ſo intertexed and wouen together that they cannot be ſeparated one from another which may be done in Muſcles.

That it is not Muſculous.

Againe, the Fibres runne through the length of the Muſcles, which is not ſo in the Tongue; for it hath no Ligamentall Fibres to ſtrengthen it as Muſcles haue, vnleſſe it be a middle one which runneth vnder the tongue. Finally, no Nerues from the Braine that ſhould giue it the power of motion do runne through the ſubſtance thereof, wherefore it cannot be called Muſculous, although I know ſome men are of opinion that it is made of two Muſcles ariſing out of the bone *Hyois*, and determining in the tip of the Tongue ſeuered by a white line: ſome ſay alſo there are two other Muſcles of which the pulp of the Tongue is compounded: but if it were made of Muſcles it ſhould onely mooue not taſte, for what Muſcle doth taſte? Wee reſolue therefore that the fleſh of it is not Muſculous.

The Fatte at the rootes.

At the rootes of the Tongue, beſides the Muſcles inſerted thereinto, there adhereth a great quantity of hard fat.

The tongue receiueth two kinds of Nerues, one ſoft which carieth ſenſe vnto it from the third and fourth coniugations, yet ſo that one branch is diſſeminated into the coate that inueſteth the tongue to be an inſtrument of *Touching*, for the Tongue is apprehenſiue of all the *Tactile* qualities, as cold, heate and ſuch like. The other Nerue is ſprinckled into the fleſh of the Tongue which is the inſtrument or organe of Taſte, and by that meanes the Tongue is made apprehenſiue of *Sapors*.

The Nerues of two kinds.

A Caution.

The other kinde of Nerues is hard, that is, Nerues of motion, to witte, the ſeauenth coniugation, which with many ſurcles is diſſeminated into his muſcles that the tongue might be mooued with voluntary motion; and becauſe this Nerue is placed in the lower part of the Tongue, the Chyrurgion or Midwife muſt be verie carefull leſt when they cut the Ligament they do not alſo cut the Nerue.

The Veines.

It hath alſo two notable Veynes called *Raninæ*, not becauſe they are like Frogges, but becauſe they are of the colour of a Frogge. They iſſue out of the inward braunch of the externall Iugular Veynes and runne vnder the Tongue, as it will appeare vnto anie man that lifteth it vp. Theſe Veynes in the diſeaſes of the mouth, the heate of the *Fauces* the Squinſie and ſuch like, are opened for deriuation; after the blood is euacuated and reuelled by the opening of the Humerarie Veine of the Arme.

The Arteries.

It hath alſo two large Arteries on either ſide one from the ſleepie Arteries which accompany the Veynes. Theſe are allowed to the tongue to maintaine the life of it, as the Veines were to ſupply it with nouriſhment.

The bodie of it.

The body of the Tongue although it bee continuall not diuided by any partition, whereby it becommeth fitter to Taſte with, to breake the meate, and to articulate the voyce: yet it is diuided or rather ſcored thorough the middeſt with a white line, which *Hippocrates in Coacis* firſt called Σιφών, that is, the *Median*, which Line runneth thorough the verie middeſt of the ſurface of the tongue diuiding it into a right ſide and a left, yet not as it is in Lizardes whoſe Tongues are forked; ſo that the Tongue as all other the Inſtruments of the Senſes is double, and therefore *Galen* calleth it a *Double Member*.

The vſes of the tongue.

The Vſes of the Tongue, although it be but a little Member yet it is of great vſe, becauſe it expreſſeth all the conceites of the minde, wherefore our wiſe Creator hath defended

ſended it with many Teeth, with Lippes, and reſtrained it with a Bridle, that beeing ſo carefully attended it might not runne before the minde, which firſt ought to conſulte and deliberate before the Tongue pronounce any thing.

The vſe therefore of the Tongue is either primary or ſecondary. The primarie vſe is, that it might be a conuenient and fit organ or inſtrument both of the Senſe of Taſting & of the Speech. Of the Taſte (which vſe of the Tongue is common to Man and beaſt) to diſtinguiſh betweene all the varieties of Sapors; wherefore *Ariſtotle* in the 11. chapter of his firſt booke *de Hiſtoria Animalium* ſaith, there is in the mouth γλῶττα χυμῶν αἰσθητικὸν, A Tongue which is the Senſator of Taſtes. The taſte which the Tongue hath it receyueth eſpeciallie from the Coate which inueſteth the mouth, and particularly from that part of it which couereth the tongue. For whilſt wee chew our meate the Tongue rowleth it ſelfe on euerie ſide of the mouth and applyeth it ſelfe to the Viands to take a ſay or Taſte of them. The primarie vſe, For Taſting.

Moreouer, becauſe we can thruſt or lill out our Tongues, we are able to diſcerne of the Sapors of thoſe things alſo which are without the mouth if the Tongue do but touch them, eſpecially with the very tip, for there ſaith *Ariſtotle* the taſte is moſt quicke in the 27 chapter of his ſecond booke *De partibus Animalium*, and therefore ſaith he, in Fiſhes onely the very tippe of the tongue is looſe, the reſt is faſtened downe vnto the Soale of the mouth. The tip of the Tongue.

Concerning the vſe of the Tongue in the voice, *Hippocrates* hath made mention in his Booke *De Carnibus*. As alſo *Ariſtotle* in the eight chapter of his ſecond booke *De Anima*; for it is the very organ of Articulation, ſo we ſaide before that thoſe Birdes which haue broad tongues may eaſieſt be taught to prattle, as we ſee in Parrats. *Euripides* therefore calleth the Tongue ἄγγελον λόγων, *The Meſſenger of the Speech*. And therefore a mans Tongue which is the beſt proportioned and moſt at libertie, attaineth to the greateſt perfection in the deliuery and variety of the voice. For although a Parrat, a Stare, and ſuch like Birds can moderate their Tongues to a kinde of faigned diſtinction of Sounds, yet in man the ſound is more expreſſe and better articulated. Beſide, ſayeth *Hippocrates* in his Booke of the *Epilepſie*, the Tongue of a man is the meſſenger of the Braine, that is, as *Rubine* well enterpreteth it of the *Vnderſtanding* and the *Wil*; but in other Creatures it deliuereth onely the affections of the Senſatiue ſoule which *Galen* calles *Rationem deliteſcentem, A ſilent ſhadow of reaſon*, which he attributeth to all creatures deuoyde of reaſon. So we ſee euen in the tongue of a man, ſometimes it expreſſeth onelie thoſe things that fall vnder the Senſe, as when wee crie for paine, or for Foode and ſuccour; ſometimes thoſe things that fall vnder our vnderſtanding as in Diſcourſe. For Speech. A mans toung the Meſſenger of the Braine.

The Secondarie Vſe of the Tongue is for maſtication or chewing, or breaking of the meate, and for diglutition or Swallowing. The Secondarie vſe Chewing.

By this motion of the Tongue thoſe Creatures that want Teeth doe ſwallow their meate whole, as Birdes; and thoſe that haue Teeth doe with theyr Tongues moue their Viandes vnto their Teeth whereby they are mittigated and broken, and ſo receyue in the mouth a good preparation for the Stomacke, which otherwiſe woulde not nor coulde not ſo eaſilie concoct them, for ſhredde meate is more eaſiler boyled then a vvhole loynt.

Againe, the Tongue helpeth the Diglutition by turning the meate ouer it towards the Gullet. By the Tongue alſo wee can licke and whiſtle, or varrie the ſounde of anie Fife or Pipe, or ſuch like. All theſe good offices the Tongue dooth in a man, in other Creatures but one or at leaſt not all. For in the perfection of Creatures (ſayeth *Galen* in the Fifte Chapter of his ſeconde Booke *De Semine*, Nature proceedeth by degrees from a Plant. The firſt Degree, is of thoſe Creatures which haue onelie the Senſe of Touching; more perfect are thoſe that Taſte, yet more that Smell, then thoſe that Heare: and finally, ſhe addeth the Senſe of Seeing which is the vtmoſt perfection of the ſenſatiue Soule. Swallowing. Degrees of perfection in Creatures.

The Muſcles of the Tongue are aſsiſtant vnto it in the performance of all his Functions of Speaking, Taſting and Rowling of the Meate: and therefore there are three kinde of Muſcles belonging vnto it which wee may call *Locutorij*, *Guſtatorij* and *Circumuolutores*, the Speaking, the Taſting and the Rowling Muſcles. The Muſcles of the tongue

ee, 1. The internall Muſcle forming this cleft or the internall Shield-griſtle.

f. 2. The opening Muſcle or the latter *Cryeoarythanoides*.

g. 2. The tranſuerſe Muſcle or the *Arytanoydes*.

The chiefe vſe of it in man is ſpeech, the chiefe vſe in Beaſts is taſting, becauſe they want hands to gather and apply their meate vnto their mouthes as men haue: but both men and beaſts when their meate is in their mouths doe rowle it with their tongue, or turne it ouer into their Gullets. The tongue muſt therefore be moueable & haue Muſcles, which Muſcles are of two ſorts, ſome Common, others Proper. Thoſe are accounted common Muſcles which belong vnto the bone *Hyois*, and thoſe proper which haue their originall from other where, and do determine into the ſubſtance of the Tongue, &

Fiue paire. they are accounted fiue paire called *Styloglosſi*, [Tab. 14. fig. 1, 2.r] *Myloglosſi*, [Tab. 14. fig. 1, 2.ſ] *Geneogloſſi*, [Tab. 14. fig. 1, 2.t] *Baſigloſſi* or *Ypſigloſſi*, [Ta. 14. fig. 1, 2.uu] & *Ceratogloſſi* [Tab. 14. fig. 1. 2.x] But of theſe we ſhall entreat particularly in the Book of Muſcles, heere it is enough to haue pointed them out.

The roote of the Tongue. Theſe Muſcles being remooued, at the roote of the tongue there appeareth a kinde of fleſh made of many glandules and fat mixed together, which ſaith *Archangelus* doth not deſerue the name of a Muſcle, ſo ſaith alſo *Columbus*, yet hee reckons it for the 11. Muſcle

cle, becauſe the Anatomiſts before him accoũted it for a muſcle. But a muſcle is not made of glandules but of fleſhy fibres.

This heape of Glandules [Table 14. figur. 1. 2. H] groweth to the roote of the Tongue that it might continually be moiſtned, for without moiſture there can be no Guſtation. So in the ſtomacke there can be no concoction without Elixation or boyling, wherefore Nature ioyned to the Stomacke the *Pancreas* or Sweete-bread a glandulous body, that from thence might continually ſteame moyſt vapours, that ſo the concoction of the ſtomacke might be made by *Elixation* or boyling. Beſide, the moyſture which the Tongue receiueth from theſe glandules makes it more glib and eaſily to be moued; for if it be dryed it wil not mooue ſo readily, as wee may ſee in thoſe that are very drie, & in hot burning Agues when the humour or moyſture of the Tongue is exhauſted. Beſide the Glandules, the Almonds alſo of the throat (as we remembred before) do continually moyſten the Tongue and help his motion. And thus much of the Tongue.

The vſe of the kernels.

CHAP. XXXIII. *Of the Senſe of Taſting.*

WEE ſayd before that there were three things required in euery Senſe; the Inſtrument, the *Medium* and the Obiect. Which three wee will ſhew in this fourth Senſe of Taſting as far as we can gather out of Anatomy.

The inſtruments of taſting.

The Phyſitians following *Galen* in his book *de inſtrumento odoratus*, and in the fift chapter of his 7. booke *de Placitis*, doe determine that the inſtrument of the Taſte is the Tongue, and that it is affected to Sapors as the Eie is to colours. But as in the Eie there is one particle which is ſaid to be the moſt principal inſtrument of Seeing, the other but aſsiſtant: ſo in the Tongue there is one ſimilar part which is the moſt principall inſtrument of Taſting, and that is the rare and laxe ſubſtance thereof, which is therefore rare & ſpongy, that it might be better ſteeped with the moyſture wherein the Sapors are conuayed. The other parts of the Tongue are but helpers and handmaids all contributing vnto the principall part. This ſubſtance, call it fleſh, or pulpe, or what you will, becauſe it was made to receiue all Sapors was to be deuoyde of all Sapor, that is *inſiped* or hauing no Taſte at all as we vſually ſpeake, and that it is ſo any man may perceiue if hee eat of the Tongue of any beaſt boyled freſh and without any ſauce.

The principal particle.

The matter wherein the formes of Sapors do conſiſt which wee call *Natura ſubiecta*, is moyſt: for without moyſture (ſayth the Philoſopher in the 10. chapter of his 2. booke *de Anima*) nothing can make an impreſsion of a Sapor, and euery thing that maketh this kind of Senſation or moueth this Senſe hath humidity in it, either *Actu* or *potentia*, that is, eyther Actually and Really or in Poſsibilitie; and by how much a thing is the moyſter, by ſo much is it the more ſauoury, becauſe all things when they are moyſt doe make a better impreſsion of their Sauour then when they are hard.

The matter in which taſts doe conſiſt.

Hence it is that thoſe things that are hard as Pepper and ſuch like, do not make ſhew of the guſtile qualities vnleſſe their vpper & ſuperficial parts do giue, or melt, or be moiſtned. The ſweetneſſe of Sugar we Taſte better when it is melted, and a corne of Salt will ſtrike the Senſe much more after it is diſſolued then before. An infuſion of Rheubarbe is much bitterer then a peece Rheubarbe held in a mans mouth. Seeing then that Sapors are not perceiued but as they communicate their qualities to moyſte ſubſtances, it followeth that the inſtrument of this Senſe muſt neither be actually moyſt, neither yet of ſuch a ſubſtance as cannot be moyſtned: but it muſt be Potentially Moyſte and Actually moyſtned; yet ſo that when it is moyſtned the Nature of it muſt be preſerued.

Hence it is that when the Tongue is either too dry or too moyſt it doth not Taſte well. For example, if a man Taſte of any ſharpe or vehement thing as Pepper, and then preſently Taſt of an other thing, he is not able to iudge well of the latter; the reaſon is becauſe the Tongue is already poſſeſſed and foreſtaled or taken vp with the former ſharpe humour. So likewiſe we ſee that thoſe that are ſicke think all things bitter, the reaſon is becauſe their Tongues are moyſtned with a bitter iuice.

Why ſick folke thinke al things bitter.

The Tongue therefore was made of an earthy and dry ſubſtance; for albeit becauſe of the ſoftneſſe it may ſeeme to bee moyſte, yet this moyſture is not *Innate* but an acquired moyſture diſtilling perpetually out of the braine which inſinuateth it ſelfe into the Toung as water doeth into a ſponge. That this is ſo it is euident, for if the diſtilation out of the head be ſtayed, the Tongue is preſently exiccated, yea ſo parched by hot vapours eleuated from the Liuer, the Stomacke and the Lungs, that it becommeth rough, yea in Agues it cleaueth

cleaueth or choppeth and the marks or ſcarres of thoſe fiſſures remaine many yeares to be ſeene; which thing (ſayeth *Bauhine*) I haue experience of in my ſelfe, for 17. yeares ſince I had an Ague, and my Tongue claue or chopped in the middeſt, and yet the marke of it is manifeſtly to be ſeene.

Bauhine of himſelfe

Galen.

Galen therefore in his Booke *de Odoratus Organo*, and in the ſixt chapter of his ſeuenth Booke *de Placitis*, hath truely taught vs that the inſtrument of Taſting was made of a moyſt ſubſtance, where hee intendeth to diliuer the qualities of the inſtruments which are moſt appropriate to the perticular Senſes. For if the Tongue be too much exiccated, the *Perteiuance* or knowledge of Sapours muſt needes periſh: and therefore Nature ſet the Almonds neare the Tongue leaſt the ayre that is continually drawne and let out by Inſpiration and Expiration ſhould drie it too much. And ſo much of the Inſtrument.

The *Medium* of the taſte.

The *Medium* of this Senſe wee take to bee the coate of the Tongue, as the Cuticle or Scarfe-skinne is the *medium* of the Touch. For (ſayth the Philoſopher in the 114. Text of the ſecond Booke *de Anima*) all things that apprehend by any Senſation we apprehend by a *Medium*, there being no Senſation made by the immediat contaction of the Inſtrument and the Obiect, although afterward in the 10. chapter of the ſame booke (not ſo well aduiſed) he denyeth that either the Taſte or the Touch haue any *Medium*, to which place we refer him that is deſirous to know his reaſons.

The obiect.

The Obiect of the Taſte are all thinges that haue any Sapour or Guſtable qualities in them. But the qualities of Guſtable things are of two ſortes, ſome properly belonging to the Senſe of Taſting as Sapours. For as the obiect of the Sight is Colour, ſo the obiect of the Taſt is Sapor; yet nothing that is without moyſture exhibiteth any Sapor to the Senſe: others are Common to all the Senſes as the Magnitude of that which is Guſtable, the Nũber, the Situation &c. VVherefore we ſay that the Tong doth Taſte the Sapor of wine, not the wine; yet from this Sapour the Soule gathereth that it is wine which wee Taſte. For wine as it is wine, and ſugar as it is ſugar are not the Obiects of the Faculty of Guſtation, but as they are indowed with Sapors or Guſtable qualities. The Soule indeed by diſcourſe of Reaſon diſtinguiſheth betweene a ſharp Taſte and a bitter, but it is by the mediation of the Senſe of Taſting; when the Senſible qualities of thoſe ſharpe or bitter things do moue and affect the Faculties of Senſation. But that a Sapor may be exactly iudged of or apprehended, the body wherin that Sapor is, muſt be broken between the Palate and the Tong, and therefore the Palate and the Tongue are compaſſed about or inueſted with one and the ſame coate.

Hence it is that euen the Palate helpeth the Taſte, becauſe alſo it receiueth the like diſtribution of the nerues of the ſame coniugation that the tongue hath.

The kinds of ſapors.

The kindes of Sapours as the Philoſopher ſayth, are accounted after the ſame manner with the kinds of Colours. For as white and blacke are contraries, and the other Colours leane to this or that Contrary; ſo *Sweete* and *Bitter* are the two ſimple contraries; to ſweet adheareth that wee call *Fattie*: to *Bitter* that which is *Salt*: and betwixt theſe are Byting, as Pepper, Harſh as vnripe Sloes, Sowre and Sharpe as Vineger. For theſe are the differences of Sapors according to the Philoſopher; concerning which he that will know more let him reſort to *Galen* his firſt Book *de ſimplic. Facultat.* where alſo he ſhall finde what was *Platoes* Philoſophy concerning the difference of Sapors.

The concluſion.

VVe conclude that the Tongue as the Inſtrument of the Taſte being neither drye nor too moyſt, nor ſteeped or dewed with any ill iuyce, doeth through his coate as through the true *Medium* Receiue and Perceiue the Sapours that conſiſt in a moyſt body, and that by a Faculty or Power iſſuing from the braine by the nerues of the third and fourth coniugation, and penetrating into the Inſtrument of Taſting, that is, the Fleſh or Pulpe of the Tongue.

For the Faculty (ſayeth *Plato* in *Theateto*, and *Galen* in the 6. chapter of his 7. booke *de Placitis*) which iſſueth from the firſt Senſator, that is, the Braine, and through the Nerues penetrateth into the particular Organs of the Senſes, and there *Perceiueth* and iudgeth of all their alterations, is a common Faculty: and therefore we call the brayne the Common Senſator, and the apprehenſion thereof the Common Senſe. And thus much of the foure Senſes (The firſt hauing beene diſcourſed of in the ſecond booke. Now wee come vnto the Voyce.

CHAP.

CHAP. XXXIV. *Of the Larinx or Throtle, which is the Organ of the voyce.*

THe Rough Arterie is diuided into the pipe which consisteth of Semicirculer gristles with a membrane, and the head of it which wee call the Larinx. It is called in Greeke λάρυγξ of λαρυγγίζω, which signifieth to cry with open throate: or of the particle λα which of it selfe signifieth nothing but in composition ad-signifieth a kinde of greatnesse, and the word ἀρύω *to draw*, because in the forming of the voyce we draw our breath deepe. Some call it φάρυξ but that is properly vsed for the *Fauces* or Chops; for the Pharinx is before the Larinx: others deriue it of λα and αἴρεσθαι which signifieth to be lifted vp, because when wee swallow or rayse our voyce very high or vtter it very base, the Larinx is eleuated as any man may see with his eyes. Some call it the knot of the Throate. The names and reasons thereof.

The Larinx therefore is the head or vpper end of the Rough Arterie ioyned in continuitie with the *Fauces*, compounded of great gristles (vnlike those that bee in the rest of the weazon both in the figure and magnitude) Muscles, Membranes, and common Organs: to be the first and most principall Organ of the tuning of the voyce; for in it the voice is first formed. What it is.

It is situated in the Necke, because it is the way of the Ayre, and in the very top of Rough Arterie that vnto it the breath which is the matter of the voyce might easily runne vp from the lungs. Neere the Chops also, the mouth and the tongue that the voyce might instantly bee changed into speech. Moreouer, because it was necessary that it should be perpetually dilated and constringed together with the Organs of Respiration, therefore it was placed on the outside afore the Gullet, that it might not be pressed with the weight of any thing lying vpon it: yea and this position is a great furtherance to swallowing also. For when we swallow our meate the Gullet is drawne downeward, but the Larynx resulteth vpward and helpeth the swallow as well by giuing way therto and leauing scope and roome as also by depressing the meate when it starteth vp as that is falling. It is placed in the very middest of the necke because there is but one Throtle, as also other single Organes are placed in the middest, that the body might be equally ballanced. Now there was but one that the voyce might bee but one. For if we should haue vttered two voyces at one time, wee could not but haue confounded two acts or affects of the minde. The situation. And reasons thereof.

The figure is round and circular but imperfect, bunching out before that it might bee more secure from outward iniuries, behind depressed that it might giue way to the Gullet and leaue space to swallow. Againe it was round, that it might bee concauous or hollow, that so the voyce might be more perfect by a plentiful affluence of the breath thervnto out of the lungs. The lower orifice also of the throtle is larger then the vpper (saith *Galen* in the second chapter of his seuenth booke *de vsu partium*) that in expiration the ayre might ascend more plentifully thereunto to make a base voyce. Finally, it is most like a *Quaile call* of any thing in the world which indeede is made in imitation of this worke of Nature. The figure.

The magnitude thereof is diuers according to the diuersitie of the age, which variety the voyce also followeth. For in children when the Larinx is narrow the voyce is sharper, small, or treble because a little ayre is swiftly moued through a narrow passage; on the contrary in old or elder age the Larynx is wider, and receiueth from the Lungs a greater quantity of ayre, whence it is that the motion is not so swift and so the voyce becommeth base; moreouer the length or shortnesse of the Larynx beare a great sway in the basenes or shrilnes of the voyce. The magnitude.

It is tyed to the rough Artery by the helpe of muscles of Membranes, as &also to the Gullet, the Chest, and the bone *Hyeis*, moreouer to the principall parts by the meditation of common Organs. The connexion.

The parts whereof the Larinx is compounded are Gristles, Muscles, Membranes, Veines, Arteries and Nerues, together with the Glandules which grew thereto. And it was necessary it should be compounded of such a substance. Gristly, that it might be hard, dense and thicke, able to resist outward iniuries. Againe, because it is the way of the breath it was fit that the cauity should be made of a hard body that might alwayes stand open for egresse and ingresse of the Ayre. For (saith *Galen*) if it had beene made of flesh or a membrane, the hole of it would haue falne and the passage should not haue bene so free for the breath The parts. Why Gristle.

and

and ſo the body haue beene depriued, not of voyce onely, but of life alſo; becauſe the reſpiration would haue bene intercepted.

Why not bony.

If it had bene bony the hardneſſe thereof would haue preſſed vpon the gullet and ſo haue hindred diglutition or ſwallowing, beſide the very weight would haue drawne downe the tongue and the bone *Hyois*, and hindered their actions; it would haue needed great muſcles to haue moued ſo heauy a body which muſt haue taken vp a greater place then in ſo narrow a roome could be allotted to them. And if the bones had bee ne ſo fine and thinne that all theſe inconueniences had beene preuented, then it would haue eaſily bene broken being placed outward, for bones will not yeeld as griſtles doe.

Columbus opinion that it is bony.

I know well that *Columbus* is of opinion that it is bony in growne men, which hee auoucheth vpon his owne diſſection of innumerable bodyes (thoſe are his words) although he confeſſeth that in young children it is gryſtly as not hauing attained his hardneſſe and ſoliditie. One argument alſo he addeth, which is, that the ſubſtance is medullous or marrowy as he hath often found, in which one thing bones differ from gryſtles. He alſo reprehenderh *Galen* for cutting vp Apes and not obſeruing that their throtles were bony, and *Veſalius* for ſhewing the Throtles of beaſtes in his publike diſſections. But *Fallopius* whom we eſteem the more oculate Anatomiſt ſaith, that ſometimes he hath found the firſt and ſecond gryſtles bony in very old men, yea ſometimes before extreme old age; but the third and the fourth gryſtles, ſaith he, I neuer ſaw bony, neither can I approue of their opinions that thinke the Larynx is bony and not gryſtly, vnleſſe it be imperfect, becauſe Nature intended it to be bony. For (ſaith *Fallopius*) if this were ſo, then we muſt confeſs that no man hath the inſtrument of his voyce perfect till he come to bee old or ſtriken in yeares, which muſt not be granted. Of the ſame mind alſo is *Laurentius*.

Diſproued by *Fallopius*.

Bauhine proceedeth further to prooue it gryſtly on this manner. It is the inſtrument of the voyce, and therefore there muſt be a proportion betweene the ayre that is beaten, & the body which beateth it, that ſo it may reſound for the forming of the voyce; for the voyce is nothing elſe but a percuſsion of the Ayre. And although ſounds doe ariſe from hard bodyes not from ſoft, as a ſponge, a locke of wooll, or ſuch like; for that the Ayre is not broken vnleſſe it light againſt a ſolid, hard and ſmooth body; yet it muſt not bee perfectly hard, for ſuch a one doth not readily cut the ayre, but ouerturns it. Nor too ſoft, for then it yeeldeth and maketh no reſiſtance, and therefore cannot make any ſound. Such a body therefore which yeeldeth moderately, and beateth the ayre gently, is the cauſe of the voyce, now ſuch a body is a griſtle. Finally, it was made griſtly (ſaith *Galen* in the fourth chapter of his booke of the diſſection of the inſtrument of the voyce) that it might be a fit foundation for the other parts whereof the Larynx is compounded: and that the Muſcles might better ariſe therefrom and be implanted thereinto.

Other reaſons why it muſt be griſtly.

Not of one griſtle.

But it was not fit it ſhould be made of one entire griſtle without any articulation, & ſo immoueable, for then it could not haue bene either ſhut or opened, dilated or contracted. It was therefore made of many annexed one to another and hauing motion, not Naturall, ſuch as is in the Arteries, but voluntary depending vpon the will. For the chiefe vſe of it being in inſpirations and exſpirations; it was meete we ſhould be able to moderate it at our pleaſures, add hereto, that being the inſtrument of the voyce to admit or expel our breath, it was more then neceſſary we ſhould haue a voluntary command ouer it. To this purpoſe Nature alſo furniſhed it with muſcles, and them with nerues for motion, veines for nouriſhment, arteries for life, and membranes for their ſtrength. She added alſo glandules to keep them all moyſt.

The number of the griſtles

It is made of 3. griſtles (ſaith *Galen*:) we ſay 4, ſo doth *Fallopius* & diuers others. For the motions of the Larynx they are double, that is wherby it is dilated and conſtringed, ſhut & opened; and therefore there was neede but of two articulations, each of which ſerue each motion. So that the dilatation and conſtriction is made by that articulation which is betwixt the firſt griſtle and the ſecond. The opening and ſhutting by that which is betwene the ſecond and the third.

The muſcles.

The Muſcles of the Larinx are either common or proper, the common Muſcles are ſixe, that is three paire. The firſt paire are called *Bronchij* [Tab. 15. fig. 7. xx.] becauſe they cleaue to the rough Arterie. The ſecond paire are called *Hyoeidei*, or rather *Hyothyroeidei*, [Tab. 15. fig. 3. h.] The third paire are called *Oeſophagei* [Tab. 15. fig. 7. ll.] The proper Muſcles are ten or fiue paire, of which ſixe do dilate and foure do conſtringe. Some of theſe are placed forward, ſome backeward, ſome without, ſome within.

The

Table 15. figure. 3. sheweth some Muscles of the Larynx with a part of the Nerue.
Figure 4. sheweth all the proper Muscles, the Cleft, the Epiglottis or After-Tongue and the Gristles.
Figure 5. sheweth the backe part of the Larynxe with the Muscles separated, the Gristles and the Epiglottis

TABVLA. XV.

b.4,5,6,7. *Epiglottis* or the After tongue.
* 4. The beginning thereof.
† 5. The roote and foundation thereof.
cc. 5. The Gristle called *Arytænoides* or the *Ewre-gristle*. *d* 4. the *glottis* cleft or whistle.
e.4. The internal muscles belonging to the *shield-gristle* or the 4. pair of proper muscles
f,4. the backward *Rings Ewre* muscles, or the second paire of proper muscles.
g,4,5. the *Ewr-muscles* or the fift paire of the proper muscles.
h.3. The muscles called *Hyo-thyroides* or the second paire of common muscles belonging to the bone *Hyois* & the Shield-gristle of the Larynx. *i*,3,7. the Gullet.
k,3,6. The forepart of the rough Artery.
l,3,7. The muscles of the Gullet called *æsophagiæi* or the third pair of common muscles.
m.3. A portion of the nerue descending into the second paire of common muscles.
nn,3,4,5. The Shielde-gristle, parted in the fourth Figure that the *Glottis* & the muscles might better be seene. In the fifte Figure is shewed the Hollowe side of the Shield-gristle, in the sixt the outward and the foreside.
o.4. The Cauitie or Ventricle.
r. 4. The laterall *Ring-Ewre* muscles or the third paire of proper muscles.
ss,4,6. the forward *Ring-shield* muscles or the first paire of proper muscles. In the sixt figure one of them is separated, the other remaineth in his owne place.
t,5. The spine or ridge of the *Ring gristle*.
u,6. A cauity in the middest of the Shielde-gristle, made for the *Epiglottis* or After-tongue.
xx.7. The muscles of the weazon or the first paire of common muscles.
yy,7. The recurrent Nerues.

The first paire we cal the forward *Crycothyroidei* [Tab.15.fig.4,[r]. but in the sixt figure the one is separated, the other remaineth in his proper seate.] The second paire we call the backward *Crycoarthenoidei*. [Tab.15.fig.5,I] The third paire are called the laterall *Crycoarthenoides* [Tab.15.figure.4,[r]] The fourth paire are called the Internal *Thyroidei* or *Thyroarythenoidei* [Table 15.fig.4.[t]] The fift paire are called *Arytenoidei* [Tab.15.fig.4 and 5[s]] The larger description and vse of these muscles looke for in the booke of muscles. We wil come to the gristles of the Larynx which we wil handle particularly in this place because they make this notable instrument of the voice, and touch them but by the way in the discourse of gristles.

The Larynx therefore consisteth of three gristles say the Ancients, of four say manie of the latter Anatomists, and we may so esteem them: one called *Thyroides*, the other called *Crycoeides* and the third *Arytenoides* which is double. These gristles when the muscles are remooued from their outside are some-what rough or rugged, to yeelde to the muscles more commodious originall & implantation. But on the inside they are smooth

The Names of the gristles.

as being inueſted with a Membrane, and beſide ſmeared ouer with a ſlimy moyſture. Of theſe Griſtles three are mooued in the modulation or tuning of the voice, that called *Cryçoides* is immooueable. The firſt and the ſecond when men grow old become ſo hard that ſome good Anatomiſts haue thought them bony. But we haue proued before that they muſt needs be Griſtly not bonie.

The firſt Griſtle.

The firſt is called in Greeke ἀσπιδοειδὴς the *ſhield-Griſtle*, or ἀσπιδοπηκὴς, for ἀσπὶς ſignifyeth a Buckler or Shield. It hath his name from the forme, [Tab. 16. fig. 2. and 3 whole] for it is like the Target that the Ancients were wont to vſe that was not round but long, the forme is yet kept by Herraldes and in Triumphes where painted Shieldes are vſed of this faſhion, the belly a little hollowe and the backe gibbous. This Griſtle lying vnder the bone *Hyois* couereth the forepart ſo as we can touch it, eſpecially in men in whom it buncheth out more then in women, which bunch or knub they call *Pomũ Adami*, *Adams* Apple, as if it ſtucke ſtill in the throate of all his poſterity, whereas the woman ſwallowed it well enough. But the true reaſon why it appeares in men and ſeldome in women, is becauſe the Glandules which are placed at the Larynx do make their neckes equall & euen.

Pomum Adami

Why womens throttles doe not appeare as mens.

It hath foure ſides becauſe of the foure proceſſes it hath behinde, for on the back it is not ioynd by the ſides. In an oxe (ſaith *Placentinus*) there are two moſt manifeſt perforations aboue, through which the proper muſcles of the Larynx receiue propagations of the Recurrent ſinnewes.

It is but one Griſtle, although oftentimes there runne a line through the middeſt. [Tab. 16. fig. 2 and 3 betweene ° and ¹¹] *Veſalius* eſteemeth it two, in men particularly, *Laurentius* eſpecially in women; howſoeuer, it is the largeſt and broadeſt of all the reſt, as taking vp the one halfe of the whole Larynx: it is therefore threefold as bigge as any of the other compaſsing the Larynx and the whiſtle or pipe thereof which we call Glottis. Moreouer in a man it is larger aboue then below.

But one Griſtle.

Connexion.

It is tyed to the bone *Hyois* by his vpper proceſſes, and by the lower to the ſecond Griſtle.

Subſtance.

The ſubſtance of it is Griſtly, thinne yet hard, the better to defend the *Glottis* or whiſtle, and to helpe the breaking of the aire in the forming of the voice. In olde men this Griſtle is ſometimes ſo hard that being exceedingly dried it becommeth Bony, yea ſometimes a very bone. It beginneth to grow harde at the ſides, the middle Line remaining griſtly for the moſt part, yet euen that alſo now and then groweth to be a bone. The exterior ſuperficies of this griſtle is conuex or gibbous, and toward the ends of the ſides it is rough, into which place the firſt paire of the Common Muſcles of the Larynx are inſerted, as alſo thoſe take their originall which we account for the thirde payre of Common muſcles of the Gullet. On the inſide it is hollow to forme the long cauity of the Larynx, by which meanes the voice becommeth ful and elegant, for we ſee that hollow things do ſound better then plaine, as it is in bels.

4. Proceſſes.

It hath foure proceſſes, [Ta. 16. fig. 2 and 3. ᴵᴷᴸᴹ] two aboue and two below, on each hand of the ſides one. With the two vppermoſt [Tab. 16. fig. 1. ᴵᴷ] it is tyed by a Ligament ſomewhat long to the lower ſides of the bone *Hyois*; [Tab. 16. fig. 1. ᴮᴮ] which by certaine diſtances is ſtrengthned with little, long, round and griſtly bodies, [Tab. 16. fig. 1. aboue K, I] eſpecially it hath vſe of them when the Tongue is put out or drawne in again.

The two lower proceſſes in men are ſhorter then the vpper, (but in Sheepe quite contrarie) [Tab. 16. fig. 2 and 3. ᴸᴹ] and are articulated by *Arthrodia* [Tab. 16. fig. 1. from ᴸ to ᴼ] with a flat head to a ſhallow cauity in the ſecond griſtle, that the *Shield-griſtle* might be mooued vpward and downward.

The Cauities

On either ſide neere the proceſſes it hath certaine recurued or bowed cauities. The vpper of which being in the middeſt [Tab. 16. fig. 2 and 3. °] is the leſſer, made for the *Epiglottis* to raiſe it vp eaſily and ſuddenly. The lower are on each ſide one [on both ſides at H] whereinto the *anterior* Muſcles are implanted. [Tab. 15. fig. 6.ᶠ] Finally, this *ſhield-griſtle* is mooueable, partly by articulation, partly by Flexion. The Articulation may be called *Arthrodia*, by which it is drawne length-waies vpward and downeward, and theſe ioynts are at the lower proceſſes which are ioyned to the ſecond griſtle, the draught is made by the firſt and ſecond paire of the common Muſcles. It is alſo drawne in length without a Muſcle being compreſſed by the 3 paire and looſened by the flexible ſubſtance of the griſtle. It is alſo mouable by flexion, for becauſe it is thin it is alſo flexible, whence

it

it ſtretcheth in breadth, it yeeldeth downeward and againe returneth vpward, and ſo the cauity of the *Larynx* is lifted vp and depreſſed, ſtraightned and relaxed.

The vſe of this griſtle is foure-fould, the firſt to make the cauity of the *Larynx*, the ſecond to eſtabliſh the *glottis* or whiſtle, the third to affoord an implantation or ſeate of reſt for the muſcles. And finally, to faſhion out the articulations neceſſarily required in the motion of the Throttle. The vſe of the Shield-griſle.

The ſecond and lower griſtle is called κρικοειδὴς, the Ring-griſtle, [Table 16 fig. 4. and 5. and 6.] for ſo *Galen* and *Oribaſius* his *Epitomizer* call it becauſe it is like a Ring: and indeed it is very like that bony ring which the Turkes weare vpon their right thumbes when they ſhoot, that they may drawe the bow ſtring with greater ſtrength. It is commonly called *Innominata*, the Griſtle without a name, becauſe the Antients before *Galen* gaue it no name, the reaſon hee giues *de diſſectione muſculorum*, becauſe they coulde liken it to nothing in the whole world; haply ſaith *Bauhine* becauſe the actions of the *Larynx* are performed by motion, now the other three doe moue, but this being as it were the Baſis and foũdation of the reſt is altogether immouable. The ſecond griſtle. Why cald *innominata*

It lyeth vnder the *Shield-griſtle* and is the Baſis of the other griſtles which it ſuſtaineth. It lyeth vpon the firſt griſtle of the Rough arterie to which it is ioyned by a Ligament, and the greateſt part of it is in the backpart of the *Larynx*, yet it compaſſeth it round about like a ring eſtabliſhing it by his hardnes. And it was very neceſſary it ſhould be like a Ring or perfect Circle, partly that the pipe might be alwaies open, and ſo way made for the ingreſſe & egreſſe of the Ayre, otherwiſe in the motion of the *Larynx* the ſemicircular griſtles of the weazon would haue beene compreſſed: partly leaſt when the Gullet is dilated or ſtretched by the ſwallowing of an hard and thicke ſubſtance, the pipe or weazon which is the way of the breath ſhould be compreſſed, whence ſuffocation or ſtrangling muſt needs follow. On the outſide and foreſide it is gibbous, narrowe, ſlender and round like the other griſtles of the weazon. [Table 16. figu. 4. and 5. R] Gibbous the better to defend it ſelfe, to helpe the ſhield-griſtle to make the cauity, to help the ſound and to dulcifie it. Thinner that it might not hinder the ayre that was to bee driuen into the ſhield-griſtle; for if it had in this place beene broader, then had the ſhield-griſtle wanted place to moue it ſelfe in. But behinde where it doth not compaſſe the ſhield-griſtle it was fitte it ſhould bee broader, and ſo well might be; [Table. 16. figu. 4. 5. and 6. S] broad I ſay like the head of a ring whereon the ſeale is grauen, and flat: otherwiſe the roundneſſe of it together with the hardneſſe would haue hindred the ſwallow. The ſituation And reaſon thereof. The figure.

Moreouer it is alſo thicker, eſpecially towards the vpper part, and that becauſe of the articulation; and that the ſlit and the *whiſtle* might bee on euery ſide defended and eſtabliſhed: adde hereto another reaſon why it was thicke, to wit, that from thence ſome muſcles might take their originall. For in the very middeſt which is the broadeſt part there ſtandeth vp a rough lyne [Table 16. fig. 6. T] which *Galen* in the 7. chapter of his booke *de diſſectione vocal. Inſtrum.* calleth the *Spine or the ridge of the Griſtle without a name.* By this lyne is made a ſhallow cauity on each ſide [Table 16. fig. 6. V X] wherein the ſecond payre of proper Muſcles are commodiouſly ſituated. But in the vpper and backward part it hath on each ſide a long knub [Tab 16. fig. 6. Y Z] or if you had rather call them bunching proceſſes (*Galen* calleth them *Shoulders*) with which the Ewre-griſtle [Ta. 16. fig. 9. ..] is articulated; in which place it is alwaies harder and thicker; ſo that that which ſeemed in childhood griſly in the middle or growne age becommeth or at leaſt ſeemeth to bee bony. In the middeſt it alſo ſwelleth a little on both hands and becommeth thicker [Table 16. figu. 6. N O] and excauated, in which cauity the lower proceſſes of the Shield-griſtle whoſe heades are flatted, are ſtrongly ioyned to this Ring griſtle by a plaine articulation. Finally, in the lower part [tab 16. fig. 4. 5. 6. S] there runneth downward a kinde of proceſſe, from whence the third paire of proper muſcles do ariſe. The ſubſtance.

This Ring griſtle by how much it is leſſer then the Shield-griſtle, by ſo much it is greater then the Ewre-griſtle: it is alſo ſomewhat narrower then the lower Baſis of the weazon, wherfore the lower part of the *Larynx* is larger then the vpper *orifice* which is in the chops. It is the hardeſt and the thickeſt of all the reſt (although it be not all of an equall thicknes) becauſe the others reſt vpon this as vpon a Baſis; wherefore alſo it is immouable that vpon this the other griſtles might be both mooued and articulated, and the muſcles which belong vnto the others herein alſo firmed and eſtabliſhed. The quantity.

It is tyed to the Shield-griſtle by the help of membranes or tyes produced from the firſt to The connexion.

to the ſecond; theſe ties are double, as alſo are thoſe which couple the ſecond with the third as *Galen* teacheth in his booke *de voce & anhelitu*, and theſe membranes doe inueſt not only the middle part of this Ring-griſtle but alſo the whole baſis of this ſhield-griſtle.

The third griſtle. It is indeed double.

The third Griſtle of the Larinx is in the ſides [Tab. 16 fig. 7.8.9.] and is called ἀρύταινα, *Sus* that is, the *Ewre*, becauſe it is like an Ewre out of which water is poured if you marke the two vpper proceſſes couered yet with their Membrane; or becauſe it is like the ſpout of a wine pot. This is commonly eſteemed and receyued for one griſtle, becauſe they are not wholly ſeparated, and perform their action together not a ſunder. VVhilſt it is yet couered with his coate it is like an imperfect Triangle: but if you take of the membranes wherewith it is couered, you ſhall perceiue that it is made of two griſtles [Tab. 16. fig. 7.8. 9. βγ.] which aboue and belowe, are looſely ioyned by the mediation of ligaments and of

TABLE XVI.

A, 1. The bone *hyois*.
B B, 1. His proceſſes.
C. 1. Griſtly ſwellings and membranous ligaments ſet by courſe to which the ſhield-griſtle is ioyned by proceſſes.
D. 1, The laterall ſhield-griſtle.
F, 2. and 3. Sheweth either face of this griſtle.
From G, to H, 2. 3. A line in the midſt of the firſt griſtle.
I, K. 1, 2, 3, 4. The vpper proceſſes of the ſhield-griſtle articulated to the bone *Hyois*.
L, M. 2, and 3. The inferior proceſſes of the ſame ſhield griſtle, which in the firſt figure are articulated to the *crycoides* or Ring-griſtle.
N, O. 6 The ſeat of the *crycoides*, or ring griſtle where theſe proceſſes grow into one.
P, 1, 5, The backe part of the Ring-griſtle.
Q, 4, 5. The inſide of the Ring-griſtle
R, 4, 5. The lower circular region of the Ring-griſtle.
S, 4, 5, 6. The hinder part of this circle
T, 5, 6. A hinder line of this griſtle.
V, X 6. A boſome on both ſides this griſtle called alſo *ventricles*.
Y, Z. 4, 5, 6. Two ſwellings of the ring-griſtle which goe into the boſome of the Ewre-griſtle.
α. 1, The *Arytenoides* or Ewre-griſtle.
βγ 7, 8, 9, Two parts of the ewregriſtle
δδ, 8, 9. The empty ſpace of this griſtle which is couered with membranes.
εε, 8, 9, The ſides of this griſtle by which it is ioyned to the ring griſtle
ζζ, 8, 9. A proceſſe of this griſtle making a little tongue.
η 9, The vpper part of the third griſtle like a ſpoutpot or an Ewre.
θ 10, The baſis of the Epiglottis regarding the Larinx continued with the Shield-griſtle.
ι 10, The tip of the After-tongue regarding the palate.
κλ 10, The baſis and top of the Epiglottis regarding the palate. μν, Both ſides of the griſtles which make the Pipe of the Rough-Arterie much like the Latine C. ξ 1, The Rough-Arterie. π 1, The Membrane which on the backeſide, tieth together the griſtles of the Weazon.

lation

the membrane that compasseth the Larinx, but in the middest they cleaue asunder or stand separated. In the middest where it is thicker it hath a ioynt wherby it is ioyned to the top of the ring-gristle where it regardeth the Gullet: and because the gristle is double the articulation also is double, which doe on each side receiue into their cauities [Tab. 16. fig. 8. 9. ⁂.] the swelling of the Ring-gristle [Tab. 16. fig. 6. Y. Z.] that so it might the fitter bee straightned and dilated.

The substance of this 3. Gristle differs, from the other two, or being softer, that it might not need the greater Muscles to moue it; it is also slenderer, fatter & moyster that it might not be dryed vp by the ayre, much lesse also then the rest that the passage should not bee angustated or streightned. The substance

It hath processes aboue & below. The vpper [Tab. 16. fig. 7. 8. 9. Z.] which being ioyned do cary the fashion of an Ewre or spout pot, are recurued outward, that they shold not incline inward and so fill vp the cauitie, whereby the free passage of the breath would haue beene interrupted. They are lax, soft, fat and flexible, that they might follow the motion of the whole glottis or whistle. These vpper processes are not altogether separated asunder, least one should haue beene drawne from the other, and therefore in a man they are aboue ioyned with a Membrane; but in Hogs it seemeth to be indeede but one processe. This part is so soft and flexible that when a man vomits it is reclined forward into the Larynx, and soe shutteth the Arterie exquisitely, that no thing might happen to fal downe into the Lungs in our vomiting. The processes vpper.

The lower processes made the *glottis*, or slit, or whistle by which the voyce is tuned. In that part they are wholly diuided [Tab. 16. fig. 7. and 9. ζ.] becaufe it was fit that the slit or *glottis* should be moueable and free. For vnlesse the egresse of the breath bee nartow the voyce cannot be formed. These processes also in the middle of the cauitie of the Larynx are couered ouer with a fat membrane, wherby the slit is made the more firme. This Ewre-gristle is made moueable, because without motion the Larinx cannot bee streightned, and againe dilated; and therefore on either side in the lower end there is a muscle inserted. Lower.

The motion proceeding of the Articulation of the *Ewre-gristle* with the *Ring-gristle* is fourefold. Flexion, Extension, and Motion to both sides; and so it is mooued vpw ard, downeward to the right hand and to the left. By Flexion the *Ewre-gristle* is driuen into the cauitie by the fourth paire of proper muscles to shut the slit. By extension it is reuelled outward by the second paire of proper muscles to open the slit. Againe, by the motion to the sides they are conioyned by the fifth paire of muscles to constringe it, as by the third paire they are separated to dilate it. The motion of the gristles to what vse they serue.

Now betwixt the Flexion and extension of the *Ewre-gristle* and of the rest, there is this difference, that in the others one motion is made for the behoofe of an other, but in the *Ewre-gristle* both motions are of themselues profitable: the Flexion, to constringe the slit that so the breath might be kept in; and the voyce made at our pleasure, the extension to dilate it againe that the ayre might be plentifully receiued in.

The membranes which tie the gristles together do make certaine bosomes or cauities betwixt the *Ewre* and the *Sheild* gristles, into which, if in eating or drinking any thing fall, be it but a little beare, which often hapeneth when the *Epiglottis* or *ouer-tongue* by laughter or speech when wee are eating is opened, because whatsoeuer it is that passeth against the wind causeth a coughing. Of these bosomes or *sinus*, *Galen* seemes to make mention in the eleuenth chapter of his seuenth booke *de vsu partium*, but since *Galen* (saith *Seuerinus Pinæus*) neuer any man made mention of them but *Gasper Bauhine* our Authour: but whether *Laurentius* had them from him I know not. *Placentinus* hauing got the hint of them, as should seeme from *Bauhine*, hath examined them very diligently in brute beasts, and findes them seldome saue in Swine, Horses and Dogs. *Aquapendens* professeth that he finds them in all creatures vsed to the earth, but in some lesser, in some bigger; yea, so bigge as a man may put his finger downe them: Swine and Horses haue the largest, those of men are not so deepe. The sinus or cauities betwixt the first and third gristles. *Bauhin.* first made mentiō of them.

The vse of these *Sinus* is to alter the attracted ayre that it fall not with violence as the deafe eares of the heart doe. They helpe (saith *Aquapendens*) to retaine the breath when the whole glottis is shut vp. In Dogs these *sinus* are like ventricles. Their vse.

CHAP. XXXV. *Of the Glottis and Cleft of the Larynx.*

The *Glottis.*

THat which is called in Greeke γλῶττις is that body which maketh the Cleft or Fiſſure in the *Larynx*, which is the chiefe inſtrument whereby the voyce is formed and vttered. [Table 15. figu. 4. d] It hath the name from the likeneſſe that is betweene it and the tongue of a flute or other pipe. The Latines all ſo call it the *Little Tongue*. For as the Sound is made by the Tong of a pipe, ſo the voyce is made by the Linguet of the *Larynx*, and as a man ſpeaketh by his Tongue, ſo the pipe is ſayde to ſpeake as it were by this *Glottis*; therefore wee call it the *Whiſtle*.

Situation. It is ſituated within for the better generation of the voyce, and becauſe the inſtrument might be freer from outward iniuries.

Figure. The figure of it is Ouall, ſharpned at either ſide, yet more toward the *Shield-griſtle*, then toward the Ewer-griſtle. It is as long as the *Larynx*, as well that the griſtles thereof might eſtabliſh it, as alſo that a man might vary with his voyce high, low, or in a middle key, or as we ſay Treble, Baſe or Tenor: adde hereto that being ſo long it is able to admit a ſufficient quantity of ayre. Moreouer as there is but one *Larynx* ſo there is but one *Whiſtle*, or cleft which beginneth from the *Ewer-griſtle* and endeth into the *Shield-griſtle* that ſo it might be moued with voluntary motion, for wee ſayde before that onely theſe two griſtles were mouable, the middle which is the *Ring-griſtle* is immouable.

How it is diuided. Notwithſtanding it may be deuided into that which in the vpper part is made eſpecially of the parts of the *Ewer-griſtle*, and that which in the lower part is formed of the membrane duplicated. This *Glottis* and cleft runneth in the middle of the *Larynx* directly from the foreſide backward, that the ayre yſſuing out of the cleft and formed into a voyce might inſtantly touch vpon the top of the Palate and the tip of the Tongue by them to be articulated. And as the ſlit or cleft of a pipe is ſometimes broade and long, ſometimes narrow and long or ſhort, ſo is it in this. For if it be long and broade the voyce is baſe, if it be narrowe it is treble or ſhrill: yet the magnitude is proportionable to the body; large bodies haue large ſlits, and little bodies narrow, from whence comes the differences of Voices.

The compoſition of it. The compoſition of it is very artificiall that the Ayre which is the matter of the Voyce might eaſile aſcend and deſcend, and might beſide receiue a fit repercuſsion. For it is made of both the proceſſes of the *Ewer-griſtle* [Table 16. fig. 7. 33.] or of the double Ewer-griſtle and a portion of that muſcle of the *Shield-griſtle* inſerted into the proceſſe of the Ewregriſtle, which two are inueſted with a membrane (making the Inner Cleft, of which we ſhall ſpeake by & by) which is not only thight to defend it but alſo moyſt which moyſture is not only ſlimy but alſo fatty: and yet this *Glottis* is moyſtned with a proper moyſture of it own, leaſt our voyce ſhould ſoone faile in diſcourſe or other vſe of it, if the *glottis* and the parts belonging to the *Larynx* ſhould be exiccated. For being of a membranous ſubſtance, the frequent motion thereof in our ſpeech or vocifiration, the perpetuall ingreſſe of ayre and egreſſe of the breath which is hot, might haue dryed it if Nature had not prepared a proper moyſture to keepe it in Temper: for as we ſee whiſtles and pipes doe need euer and anon to be moyſtned or elſe they will not ſound ſo well; ſo if this *Whiſtle* of the *Larynx* had not had a naturall moyſture, the voyce muſt needs haue fayled, as wee ſee it doeth in thoſe that are ſicke of burning Agues, or trauell in hot weather, who cannot ſpeake before they haue moyſtned their throttles, or if they ſpeake their voyce is ſtridulous or whining, which kind *Hippocrates* calleth *voces clangoſas* in *Prorrhet.*

How moyſtned.

Vox clangoſa.

This moyſture makes the ſurface of the *Glottis* or whiſtle to be ſlippery, yet is it beſide ſmooth & glib leaſt the ayre lighting vpon vnequall parts and ſo yſſuing vnequally ſhould make the voyce harſh and vnpleaſant. Notwithſtanding it was fit this moyſture ſhould be moderate, becauſe thoſe bodies that are too wette doe ſound woorſe then thoſe that are dry. VVhence it is that in Rheumes and Murrhes the Voyce is hoarſe, becauſe the *Larynx* is dewed with too much moyſture, but when the moyſture thereof is Naturall it maintayneth the Voyce a long time without helpe, the rather becauſe as wee ſayde the moyſture is not thinne that it ſhould ſoone be ſpent, but viſcid and fatty. And haply this made *Galen* ſay that the *glottis* was not onely membranous but alſo fatty and glandulous. The *Glottis* alſo by this meanes being ſoft and ſupple is more eaſily dilated and contracted, for it was neceſſary it ſhould open and ſhutte as might ſerue beſt for the different Expiration of the breath.

How the voice becommeth hoarſe.

Galen.

For

For the *glottis* is either at reſt or is mooued, when it is at reſt it ſerueth for the inſpiration of ayre; when it is mooued it is the inſtrument of the voyce, for the forming whereof it hath a double motion; one of dilatation another of conſtriction. The dilation is the cauſe of deepe and baſes voyces; the conſtriction is double, either to make the ſlit narrow and then the voyce is treble and ſoft; or altogether to ſhut it vp, whereby the breath is violently reteined with in, as when wee ſtriue to lift great weights, when women are in the pinch of trauell, and in ſuch like violent actions. Wherefore as it is muſculous it maketh the motions of dilation and compreſſion; as it is griſtly it affordeth the ioynts whereon the motion is made, and ſtrength to ſupport the motion that it ſhould not bee ouerturned by the breath; as it is membranous it is more fit to be dilated and conſtringed, the ſlit is formed the better and the muſcle is defended. The reſt of the Glottis. The motion thereof.

But beſide the ſlit made by the *Ewre-griſtle*, in the inner cauity (and that in man onely) there is formed another ſlit of the concourſe of two membranes. For from the fore and middle part of the *ſhield-griſtle*, the membrane wherewith it is inueſted on the inſide in the middle iuſt againſt the *glottis* becometh double and more ſolid, and attaining ouer to the backeſide of the Larinx is tyed to the inſide of the *Ring-griſtle* not farre from the *Ewre griſtle* that ſo it might be kept ſtretched. Betweene theſe duplicated membranes there remaineth a long cleft running from the backeſide forward [Tab. 16. fig. 7. 8. 9.] which is made broader when the *ſhield-griſtle* is dilated by the muſcles, and ſo the voyce becometh baſe: as on the other ſide it is treble if it be anguſtated or ſtreightned. And this is holpen by the diuiſion of the *glottis*, for both ſlits are at the ſame time dilated, and at the ſame time conſtringed. *Arantius* maketh mention of this internall ſlit, and is of opinion that it is the chiefe place wherein the voyce is tuned, and that the diuiſion of the *glottis* is but aſſiſtant thereunto. The inner ſlit *Arantius*

The vſe of the *Glottis* is, to be the chiefe inſtrument of the voyce, or principall part in the Larynx which performeth the action, that is, the voyce; for that is the proper action of this inſtrument. For the ayre paſsing is reſtrayned & broken, & ſo produceth the voice neither can any voyce be made vnleſſe the paſſage be ſtraightned (and therefore *Galen* ſaid well, that the Larinx without the *Glottis* cannot frame or forme a voyce, no more then the eye can ſee without the Criſtalline) now it is ſtraightned when it is mooued, that is, when it is dilated or contracted, for it is in our power, ſaith *Galen* in the ninth chapter of his eight booke *de placitis*, to ſhut or open the mouth of the Larinx when wee will, and as wee liſt to cloſe or looſen it, ſo we make our voyce baſe or treble; for if wee let our breath paſſe out lightly and gently, no ſound accompanieth our exſpiration, but if the breath be powred forth ſuddenly and vehemently, then with the expiration there iſſueth a voyce alſo. The vſe of the Glottis. The chiefe inſtrument of the voyce. *Galen.* Wee may breath without a voyce.

CHAP. XXXVI. *Of the Epiglottis or Aftertongue, and his Muſcles.*

THat which the Grecians call ἐπιγλωττὶς becauſe it is ſet aboue the *glottis* or whiſtle of the Larinx, the Latines cal *minor Lingua* or *Lingula fiſtulæ*, but becauſe the *glottis* is alſo called *Lingula*, we haue rather called it the Aftertong. It is a griſtle and a couer of the cleft of the Larinx made to fall vpon it when we ſwallow, that no thing ſhould ſlip aſide into the weazon [Tab. 17. it is placed betweene the firſt and ſecond figure, but inuerted and was cut away from figure 1. at ᵃᵃ but Tab. 15. fig. 4. 5. 6.ᵇ.] *Hipocrates* calleth it *claſtrum* the lock or baſe. What it is.

Ariſtotle in the twelfth chapter of his ſecond booke *de Hiſtoria animalium*, thinketh that all creatures which lay Egges doe want this *Epiglottis*, but doe cloſe exquiſitely or dilate againe the top of the Larinx as they pleaſe to keepe any thing out of their lungues without any vſe of ſuch a couer as is neceſſary in other creatures. *Placentinus* addeth that Frogs haue none of it.

It is ſeated betweene the Larinx and the tongue, and if you looke vpon the ſuperficies of the membrane that compaſſeth the tongue which is continuall with this *Epiglottis*, it may be eſteemed to be as it were a part of the tongue: whereupon ſome haue thought that it hath his originall from the roote of the tongue, whereas it is more likely that it ariſes from the *ſhield-griſtle*. For it ariſeth vpward with a large baſis recurued forward from the inward and higher part of the ſhield griſtle, [Tab. 15. fig. 4.*. fig. 5.†] afterward it grows broder a little and a little, and becommeth like a round Arch, but in brute beaſts it is by degrees anguſtated and determineth into a broade and ſharpe edge. In the baſis thereof it is tyed to the ſhield-griſtle, all the reſt of it is looſe and hangs at libertie. The ſituation Connexion.

The forme. The forme as ſayth *Hippocrates* in his 4. booke *de morbis*, is like the Iuy leaue, for the Baſis is broad and arched forward into a roundneſſe; or it is like a little tongue as *Pliny* and *Celſus* write. *Veſalius* compares it to a triangle. *Columbus* to a litle ſhield curued & ſtraighted toward the edge. *Aquapendens* to a triangle which hath crooked ſides.

The vpper part called the backe which is next vnto the Palate, is a little conuex and buncheth outward, the lower ſide which is next to the cleft or whiſtle is hollow or a little concauous. The bredth of it is not only enough to couer the cleft but to ſpare.

Rigid or ſtiffe. It is alſo of it owne Nature rigid and ſtiffe ſtanding, that the pipe of the rough arteria, might remaine open, leaſt the heart ſhould bee ſuffocated; yet is it flexible that it might perfectly ſhut vp the cleft ouer which it is diſpoſed: beſide, if it had not beene flexible the waight of the meat and drinke would not haue depreſſed it in the ſwallowing: againe, if it had not beene ſtiffe and rigid, when it is once borne downe vpon the cleft in the ſwallowing of meate, it woulde not haue ſtarted vp againe to giue way for the yſſue of the breath.

Yet ſoft too. Wherefore the ſubſtance of it is griſtly and thinne, ſomwhat ſofter then the other griſtles, yet ſo, that it is ſofter, thinner and more flexible on that ſide that reſpecteth the Palate, eſpecially in the very end neare the gullet it is very ſoft, and couered with a fatte membrane. For when the creature breatheth it is lift vp of it own accord to make way for the ayre, but when hee ſwalloweth it coucheth vppon the *Larynx* leaſt the meate ſhoulde fall into the Lungs.

The reaſon thereof. For that which is ſwallowed (as *Galen* well hath written in the 16. chapter of his ſeuenth booke *de vſu partium*) falleth firſt vppon the rootes of this After-tongue, after it is carried vpon the backe of it which maketh it to couch or incline. Theſe motions this *Epiglottis* could not haue had if it had bin either mẽbranous or fleſhy, becauſe it would haue alwayes lien depreſſed, or being once depreſſed it would hardly haue been rayſed vp againe, neuer erected vp right. Neither could it haue beene bony, for then it would alwayes haue bin rigid, neither could it haue bin depreſſed with the ſwallowing of meats and drinks. Wherefore with *Galen* we think that the motion of the *Epiglottis* or After-tongue in a man is Naturall, and that the cleft is couered and againe vncouered, not by the helpe of muſcles but by the waight of thoſe things which we eat and drinke.

The motion of it in men Natural.

In ſome beaſts voluntary. But in beaſtes that chew the Cud there are ſome muſcles found, as wee ſhall ſay in the Hiſtory of the Muſcles & ſhew them ſomewhat particularly, becauſe it is an ordinary thing for young practitioners in Anatomy, to exerciſe themſelues in diſſecting of the Throtles of Oxen and ſuch like: But in the meane time we muſt remember that the *Epiglottis* is couered ouer with a fat membrane much like to the nature of a ligament, which at the ſhield griſtle is full of fat.

The vſe of the *Epiglottis*. The vſe of the *Epiglottis* is to couer the *Glottis* or whiſtle when we ſwallow our meate; for if at vnawares any of the meate do ſlip into the wezon, we preſently keake and are neare ſtrangling till by coughing it be gotten vp again, the reaſon is, becauſe that which deſcendeth taketh away Reſpiration. So *Anacreon* the Poet was ſtrãgled with the ſtone of a Raiſon. And *Fabius* the Senator drinking a cup of Milke was choaked with a haire that was therein.

Alexander Benedictus tels of a woman who would haue giuen her Sonne a Pill and was conſtrayned to thruſt it downe his throate with her finger, ſhe thruſt it into his wezon and hee died inſtantly. Becauſe therefore a man cannot liue without Reſpiration, when that Reſpiration is interrupted Nature rowſeth vp her ſelfe to make reſiſtance, and ſo we ſtraine at the leaſt crumme that fals the wrong way. Yet we muſt not imagine that the cleft is ſo exquiſitly cloſed but that ſome part of the drinke ſlippeth into the rough artery, gliding downe by the ſide of the *Glottis* though it be not felt. And this way we thinke diſtilations doe yſſue out of the head into the Lungs, which though they bee very aboundant yet hee that is ſicke cannot feele them, eſpecially in ſleepe they gather very faſt together. Howe *Hippocrates* proued that a part of the drinke is conuayed vnto the Lungs, wee haue before ſhewed by the cutting of a Hogs throate inſtantly after he hath drunk water coloured with Vermilion or any ſuch like, for you ſhall finde the very colour in his weazon. Againe, if ſome of the drinke did not ſlip downe by the ſides of the rough Artery, it were in vaine to preſcribe Ecclegmes, Syrups or Lozenges in affects of the Cheſt. But we finde by experience that all theſe doe helpe expectoration and make the ſpittle come vp more roundly, if they be taken by little and little the head reclined backeward, licked off a knife, a Liquerice ſtick or ſuch like, or if the Lozenges be conteyned in the mouth til they melt of themſelues and

Part of the drink gets into the wezon.

An inſtance.

The vſe of pectoral medicines.

Table 17. Figure 1. and 2. ſheweth the tongue cut from the bodie, and the Muſcles thereof. In the firſt the right ſide of it, & in the ſecond his Muſcles ſomewhat vncouered.
Figure 3. ſheweth the bodie of the Tongue diuided according to the length of it and his Ligament.

b 1. The *Epig ottis* or After-tongue.
c, c. The *Arytanoides* or the Ewre-griſtle.
1, 1. The *glottis* or ſmall cleſte of the Throttle.
ee, 1. The internall Muſcle forming this cleft or the internall Shield-griſtle.
f. 2. The opening Muſcle or the latter *Crycoaryth enoides*.
g. 2. The tranſuerſe Muſcle or the *Arytanoydes*.

and paſſe inſenſiblie into the Larynx. And heerein we imitate *Galen* in the ſeuenth chapter of the fourth Booke of his method, where being to cure one that had an Vlcer on the inſide of the Rough Arterie, cauſed the Patient to lye vpon his backe, and a moyſt Medicine that was fit for the Vlcer to bee giuen and to be held in the mouth as long as hee could, and to relax and remit the Muſcles of the place, for ſo ſaith *Galen* by little and little ſome of the Medicine wil diſtil into the Arterie,

But the reaſon why water or drinke when it falleth into the Weazon cauſeth a cough is, becauſe as *Hippocrates* ſaith it maketh a diſturbance for that it oppoſeth the Reſpiration. For the Liquor that falleth downe by the ſides of the Arterie, doth not withſtand the egreſſe of the aer, rather it furthereth it by making the way moyſt & ſlippery. Hence we may ſee how ignorant the Ancients were in Anatomy, as *Plato*, *Philiſtones*, *Dioxippus*, and ſuch like, who conceiued that the drinke went into the Arterie or Weazon, and ſo into the Lungs, and the meate through the gullet into the ſtomacke. Againſt this opinion *Hippocrates* diſputeth in his fourth Booke *De Morbis*, that is, againſt thoſe that think the

Why wee cough when anie thing fa'ls into the weazon.

the drinke falleth into the Lunges, yet hee doth not denie but ſome drinke ſipeth that way as we haue ſaide before. Wherefore (ſaith *Galen* in the ninth Chapter of his eight booke *De Placitis*) if *Plato* thought that all the drinke was conueyed into the Lunges he cannot be excuſed becauſe his ignorance is euen palpable: but if he thinke that a part of the drinke is deriued into them he is not altogether deceiued.

Ariſtotle. The like we may ſay of *Ariſtotle*, who thought it an error to ſay that the drinke paſſed into the Arterie becauſe there is no thorough paſſage for it, as there is out of the Stomacke into the draught. For verily if that be auouched of all the drinke it is a verie abſurd conceite: but if it be meant of a little it ſeemeth to be true.

Another vſe. Another vſe of the *Epiglottis* or After-tongue is to ſtrike the aer which ariſeth from the Lungs into a tuneableneſſe, eſpecially if it ariſe with a force or impetuous violence thereunto. And this vſe we haue out of *Laurentius*.

CHAP. XXXVII. *Of the Membrane of the Larynx or Throttle which is the Ligament thereof.*

The mẽbrane of the Larynx THE Larynx is bound about with a Membrane which is common with the Membrane of the mouth, to be a defence to it both outwardlie and inwardly, and whereby the aire being gently and eaſily ſtrucken, might make the voice pleaſant and moderate. Firſt inwardly, the whole cauitie is compaſſed & ſo it is led ouerthwartly to the vpper part of the Larynx, being diuided in the middeſt of his length it maketh a little cleft. But outwardly it doth partly encompaſſe the external ſuperficies, and partly it inueſteth inwardly the Griſtles and Muſcles.

Why the membranes of the Larynx are moyſt. They are ſteeped in a certaine ſlimie humidity, partly leaſt the Reſpiration being warme, ſmoky and drie, ſhould make the parts drie alſo, partly that the *Epiglottis* might be cloſely ioyned to the *glottis* and ſo his exccation might bee hindred, which humidity is more aboundant within, yet ſo that in thoſe which are ſound it is neither more copious nor more ſcarſe then the inſtrument of the voice doth require; by it alſo it is poliſhed and ſo the voice is made pleaſant and equal, for being moiſtened with a kinde of humidity it doth familiarly beate the aire, whence the ſweeteneſſe of the voice proceedeth. This may be proqued by the example of Muſitians, who going about to ſounde longer Pipes or Trumpets whether they be of Braſſe or wood, will ſomewhat moyſten them (haply with their Spittle) whereby the voice may bee made more delectable, elſe becauſe of too much ſiccitie the ſounde is not onely vnpleaſant and harſh, but is made with more difficultie and labour, likewiſe if it be too moyſt the ſound is obtuſe, wherefore we ſaide before the voice is made hoarſe by the humours which come out of the Braine into the Choppes.

Whence a pleaſant voice proceedeth.

Why they are craſſe & thick. Theſe Membranes of the Larynx are for the moſt part thicker and ſtronger then all the reſt. The outward is verie craſſe and laxe and as it were rough and rugous; for aboue the *Epiglottis* it is lax and craſſe, where it is bound to the ſides of the third griſtle, and betwixt it and the griſtle, eſpecially at the baſis, there is a little Fat growing. It is lax, that it may more eaſily be incurued and turned vpon the Larynx and be mooued in deglutition or ſwallowing, in an acute and graue voice vpward and downward.

Why they are laxe. And it is craſſe, ſomewhat hard alſo and denſe, becauſe by that way meate ſometimes halfe chewed, hard and in great gobbits muſt paſſe of neceſsity.

Some there be which thinke that this Membrane is increaſed with fleſhy fibres, and that it becommeth a muſculous membrane both in men and beaſts to help the lifting vp of the Epiglottis, which Fibres are compaſſed with a little skin both outward and aboue, leaſt it ſhould be hurt in the paſſage of the meate.

The Inner coate. The internal Coate or Membrane which is more craſſe in the cauitie of the Larynx or Throttle then it is in the pipe of the Artery, is ſoft, ſtretched and ſlipperie, becauſe the cauitie was to be made poliſhed and ſmooth, but where the cleft of the Larynx doth cloſe, this Membrane on both ſides is by often compreſsing of it when wee holde our breath, made more hard and callous, and with the ſubſtance doth change the colour & waxeth more white. But of this Membrane we haue ſpoken ſomwhat before in our Hiſtory of the Rough Artery. Concerning the veſſels alſo and the Glandules of the Larynx we ſhall ſpeake in their proper places.

CHAP

CHAP.XXXVIII. *Of the ſound and the voyce.*

IT is ſufficiently manifeſt by that which we haue ſaid, that the voyce is an action of the Larinx, and that it is the inſtrument of the voyce, and that the *glottis* or whiſtle is the firſt and immediate cauſe of the voyce and this is *Galens* opinion, wherefore we will diſcourſe a little of the voyce. How a voice is made.

The voyce therefore according to *Ariſtotle* is a certaine ſignificatiue ſound of a liuing creature, or as *Galen* defines it, the voyce is the Ayre ſtrucken, and a ſound is the percuſsion of one body againſt another *in* ſome other. There be therefore three things required to the effecting of a ſound, to wit, two ſeuerall bodyes which doe mutually ſtrike one another, & the ayre in which the purcuſsion is made, which ayre is beaten and broken betwixt the two bodies. The definitiō of a voyce.

But that theſe bodyes thus mutually knocking one another, may effect a ſound, firſt, it is required that they be ſtretched, by which tenſion or ſtretching they are ſomewhat hardened, therefore *Ariſtotle* ſuppoſed that they ought to be hard, for a ſponge & wooll may mutually ſtrike one another and yet no ſound be made. But if you ſay that ſounds are oftener made by hard bodyes, yet it is true alſo that ſometimes they are made by ſoft bodyes, for if you ioyne your lips together a kind of whiſtling may be heard, but this proceedeth from their tenſion whereby they thruſt out the Ayre by compreſſing each other. What things are required to a ſound. The bodyes muſt be hard.

Moreouer, they ought to haue a broade and plaine ſuperficies, for two needles ſtriking one anothet doe make no ſound. Againe, the percuſſion ought to be vehement and quicke, for if you gently put your hand to any thing no ſound is heard. But if beſides, theſe bodyes be poliſhed and concauous or hollow, and of a ſolid and ayry matter, ſuch as braſſe and glaſſe is, then the ſound will be greater, more plaine and delightſome, which may bee ſhewed in bels and muſical inſtruments for ſuch bodyes containe a great deale of ayre in them, which airy when it is moued and ſeeketh a vent, doth euery way ſtrike about the ſides and euery way cauſeth a reſonance or reſounding. Broade and plaine. And poliſhed for the better ſound.

Now ſeeing a voyce is the ſound of a liuing creature, or a certaine ſpecies or kind of ſound; there muſt be euen ſo many things required to it as a ſound. Namely, the aire for the matter, the bodyes which by compreſsing the ayre doe as it were breake it for the efficient cauſe; & we may adde the place which is the head of the rough Arterie. What is required to a voyce.

The ayre which is required for the forming of a voyce is that which we returne by expiration, and this is the matter for the generating of a voyce; for that which is inſpired is prepared for the refreſhing and nouriſhment of the heart and Inbred heate. Wherefore a mans voce is ſo long continued as the expiration endureth, and when it fayleth the voyce vtterly ceaſeth. Now this expired aire is broken by by the ayry inſtrument and ſo the voyce is formed at this breaking, and where it is broken there percuſsion doth forthwith follow. But it may be demanded which of the ayry inſtruments can ſtrike and preſſe this ayre. The ayre expired.

The Cheſt and the lungs do not make this voyce, becauſe their motions be *Diaſtole* and *Syſtole* or dilatation and conſtriction which make no voyce. Neither is it the pipe of the Rough Arterie or the greateſt part of the weazon becauſe it wanteth muſcles: wherefore it cannot perfect the voyce which is a voluntary worke. By which of the ſpirituall inſtruments the ayre is broken.

Moreouer, if you cut the weazon below the Larinx or head, the creature will yet expire freely, but he will not vtter any voyce: and if againe you bind this inciſion the voyce will returne. Neither is it the noſthrils which is the cauſe of the voyce, becauſe they are onely paſſage, nor the mouth becauſe it is onely a receptacle, nor the tong becauſe they which be dumbe haue their tongs and reſpiration ſound; ſo they which haue their tongue cut out doe yet vtter ſome kind of voyce. It remaineth therfore that amongſt the ayry inſtruments onely the Larinx or throtle is it which is as it were, the ſhop or worke-houſe wherein the percuſsion is made, which the fabricke and ſtructure of it do ſufficiently ſhew. It is broken by the throtle and why.

For it hath Muſcles which are neceſſarily required to the effecting of a voyce which is a voluntary action: It hath alſo nerues which affoord the motion, Griſtles alſo which are hard bodyes, broade, ſmooth, poliſhed and concauous or hollow, vpon which the ayre may eaſily be broken, conſtringed and compreſſed and therwithall reſound. It hath alſo a cleft which is requiſite vnto the breaking of the ayre that ſo a ſound may be made. For this breaking of the ayre cannot be done vnles it paſſe through by ſome ſtraight & narrow way This Eliſion or breaking is made through the cleft when it is conſtringed and anguſtated or ſtraightned by the articulation of the *Arytanoides* or Ewre-griſtle and the Muſcles. How this aire is broken.

Wherefore

Wherefore *Galen* writeth that a voice cannot be made vnleſſe the paſſage be ſtraite, neyther can that paſſage be well called ſtraight, vnleſſe it tendeth by little and little from a large paſſage vnto a ſtraighter and is againe amplified or enlarged from that ſtraightnes. After this breaking doth a percuſsion preſently follow, either againſt the aire or againſt a ſolid bodie, and therefore *Galen* ſuppoſeth that the *Vuula* is like the quill of a Citterne in the forming of the voyce, becauſe the aer being blown out is forced againſt the *Vuula*.

Vehement impuſiō of the aire is required vnto the ſound.

But not onely the ſtraitneſſe of the cleft is neceſſary vnto the voice that the paſſage of the aire be narrow, but alſo the vehement impulſion of the breath, ſo that it ſuddainlie and at once breake forth: for when either of theſe faile the voice cannot be made; which ſudden and vehement expiration *Galen* calleth ἐκφύσησιν or efflation. The other cauſe therefore of the Voice is efflation without which it cannot be made though there maie be efflation without any voice.

How exſufflation is made.

This exſufflation or ſtrong breathing out is made by the Muſcles, binding the Cheſt & the *Abdomen* or panch, by which conſtriction the Lungs are depreſſed and conſtringed, the Midriffe is incurued towards the cauity of the Cheſt, whereby his cauity is made ſtraiter and the breath carried vpward out of the Lunges thorough the rough Artery, (wherefore *Galen* ſaide, that the voice was prepared in the Rough Arterie when the aire being ſhut vp and compreſſed there, doth after a ſort attaine the ſtate and condition of a ſolid bodie before it yſſue through the cleft) and beeing extruded or thruſt out with violence and force: through the ſtraite cleft, yeeldeth that ſound which we call a Voice.

The vſe of the voice.

Galen expreſſeth the vſe of the Voice in theſe wordes, that it is the Meſſenger of the Thought of the mind, and therefore worthily is accounted the principall of all the actions of the Soule.

And thus are we arriued at the end of this Booke of the Senſes wherein we haue omitted the Senſe of Touching becauſe it is already handled in the ſecond Booke. Now we come vnto the Controuerſies.

¶ A Dilucidation or Expoſition of the Controuerſies belongnig to the Senſes *and their Inſtruments, as alſo of the Voyce.*

Placentinus his Præface.

Of the Excellency of the Senſes.

The contemplation of our ſelues dooth further vs in the knowledg of God.

WHen I compare Diuine things with Humane and in like maner Humane with Diuine, and with a through examination do diligentlie view the properties of them both; I can finde no man ſo nere a kin to the myſticall Nature of God, as thoſe which make good vſe of that Oracle of *Apollo*, γνῶθι σεαυτόν, *Know thy Selfe*. For ſeeing that admirable Architector and Maker of all things did make the bodie of man according to his owne Image, it cannot be but he which is well skilled in the Fabricke and VVorkemanſhippe of himſelfe, vnto him I ſay will the Nature of the Creatour and Arche-tipe more plainely appeare, becauſe hee which is well read in his owne body, ſhall ſee in all euen the leaſt operations of his minde or actions of his bodie a liuely Impreſsion and infallible markes of Diuinity. And hence it was that they which vſed no diligence to prye into the ſtructure of their owne bodies, were worthily reproached by the Ancient with the ignomious Title of *Epicurean* Hogges. for ſuch men beeing enſnared with the allurements of their Senſes, were onely carried thither,

thither whether they like Beasts they were transported by the force & rage of their Senses measuring the chiefe felicity of man by the narrow scantling of the soule,& naked pleasure of the body. But *Ouid* doth manifestly shew how farre a man differs from a beast where he singeth.

Pronaq; cum spectant animalia cætera terram,
Os homini sublime dedit cælumque tueri
Iussit, et erectos ad sydera tollere vultus.
VVhen other creatures on the earth doe pore,
Nature gaue man a high erected looke:
The heauens to view, and Dieties to adore,
And reade the Characters in that faire Booke.

Why beasts looke downe, and men vpward.

Surely a hidden mysterie of a Poet, and words truly beseeming a man, wherein hee would beate vpon nothing but this, that man being mindfull of his diuine originall, may by the contemplation of himselfe ascend higher into the mysticall knowledge of his diuine Creator. Seeing therefore it is a matter of so great moment to know our selues: It seemed to me not onely commodious,but of absolute necessity to compose some small Treatise (though a taske of hard labour) wherein as in a most cleare glasse a man may take view of himselfe,and see his owne nature as it were deciphered with *Apelles* Pencil.VVherefore I will here exhibite both the essentiall parts of man, to wit, his Matter and Forme, together with their functions and proprieties, as well particular as common,obseruing the order of Nature, because wee cannot come perfectly vnto the knowledge of man, vnlesse first wee doe well see into the Essence both of the body and the soule. Now the knowledge of the soule cannot be made manifest but onely by her operations,which also seeing she doth not performe without the helpe of corporall organs,there is a necessity imposed, that wee also vnderstand the exact composition of the body. But because in the deliuerie of the method of Arts we ought alwayes to procede from vniuersals and such as are better knowne vnto vs,vnto particulars, and that the faculty of sensation is as it were an vniuersall thing,as being dispersed through the whole Systeme and frame of the body,the order of Nature requireth that I treate of it in the first place.

Why he first treateth of the Senses.

Moreouer,amongst all the offices of the soule this faculty of sensation seemeth to challege the chiefe place, neither that faculty only which is lodged within and receiueth the images of things, and after deliberation or discourse doth iudge of them; but much more that whole sett of senses which doe outwardly *perceiue* all sensible obiects, and perceiued, doe carie them to the Tribunall of the Internall sense and doe so enforme it, that it is able to pronounce a true iudgement concerning them. For without these externall senses, wee must needes acknowledge the Internall imperfect and vnprofitable. For if wee conceiue any thing in our minds,& nourish that conceit by discourse,againe and againe ventilating it to and fro, wee shall obserue that all things had their originall from the outward senses; for neither could colours, odours, nor sauours be knowne, neither could the Internall sense discourse of sounds, or of any Tactile qualities without the message as it were, and information of the outward senses, by which the Images of thinges are imprinted in it. And with this doth that Philosophicall axiome agree. *Nihil est in intellectu quod non prius fuerit in sensu.* Nothing is in the vnderstanding which was not before in the sense. The Prince of Philosophers esteemeth this the fountaine of all Artes and Sciences. And surely if any man setting aside the assurance and the authority of senses,shall seek for the grounds and *euidences* of Arts and other Obiects else-where then from the senses, hee shall not onely entertaine into his minde a dissolute and vaine confusion,tossed hither and thither without any stedfastnesse, but also calling in question the most sure foundations of Nature, shall cast himselfe headlong into a dungeonof perpetuall and intricate obscurity.

All Arts haue their beginning from Sense.

Quid referemus enim quod nobis certius ipsis
Sensibus esse potest; quo vera et falsa notamus.
For what more certaine euidence of things can be obtayned,
Then that which true or falsse we iudge by outward sense vnstayned.

VVhence shall hee haue the grounds of Demonstration which endeauoureth to derogate from the credit which is due vnto the senses,which are the foundations of al Sciences?

For

Demõstration from Sense.

For Demonstration is from vniuersall things, and such vniuersals doe arise and spring out of singulars: but the externall senses doe *perceiue* all singular things. Now there is none so ignorant which doth not see what will follow hence. The same thing *Lucretius* confirmes in these verses.

Inuenies primis a sensibus esse creatam
Notitiam veri, nec sensus posse refelli,
Qui nisi sunt veri, ratio quoq; falsa sit omnis.
The knowledge of all truth who seekes, must hold
From outward senses first to haue proceeded
Those Demonstrations cannot be controld,
Or could they, Reasons selfe should be deceiued.

Hence it is, saith *Aristotle*, that such men are vnfit for some Arts and Sciences, to whom Nature hath from their birth denied any of these senses.

VVhosoeuer therefore doth not content himselfe with the infallible credit of the senses, is worthy with *Anaxagoras*, who called into question the whiteneſſe of the snow, as *Aristotle* remembreth of him, to be giuen ouer vnto the doubtfull and suspended vncertainty of the *Pirrhonij* or Scepticks, & to waite till the things themselues shall tell him what their seuerall natures are. But we in the mean time admiring this maiestie & certainty of the senses, will make entrance into so faire & pleasant a field of discourse, and handle euery one of them in particular, beginning with the sense of Touching, which as it is more common then the rest, so without doubt deserues the first place: For this is the ground of all the rest, and doth consist in the ἐυκρασία, or moderation and temperament of the foure Primarie qualities. And hence it was that *Aristotle*, and with him all other Philosophers haue iudged this sense woorthy that honour to bee called κατ᾽ ἐξοχήν or by a certaine eminencie or excellencie without adding thereto any Epithite *The Sense*, as if they should haue said the onely Sense of all Senses. And that not vnworthily; seeing (as the same *Aristotle* affirmeth) euery sense is a kinde of Touching, as whereof the whole company and set of the other Senses doe stand in neede for the better perception of their obiects. As for example. The Taſt neuer should discerne of sapours except the gustible matter were touched by the spongie body or pulpe of the Tongue; neither could the Organ of smelling receiue any odours vnlesse the perfume of odoriferous things should touch the same. The same are we to thinke of the other Senses, to which in like manner is required, though not a Mathematicall yet a Physicall Touching: what neede we adde more? It is the Sense of Touching, which perfecteth the operations of all the other Senses, and yet it selfe needeth not the helpe of any. Yet this I adde moreouer, that this sense is capable of the Nature of many more contraries then the other Senses, for it iudgeth of Heate and Colde, Moyst and Dry, Soft and Hard, Light and Heauy, Slender and Grosse, Rare and Dense, Smooth and Rough, and an infinite number of that kinde. On the contrary, the Sight doth perceiue nothing but white and blacke; for Red, Yellow, Skycoloured, and other such like, are not contrary but intermediate colours, and so of the rest: that I may also lightly passe by this, that al other Senses are restrained within some small organ about the brayne, but the Touching is diffused through the whole body. These arguments doe sufficiently commend the preheminence of this sense of Touching. Yet if you please to attend, and more accurately consider these which follow, you shall see the maiestie thereof to shine more plainely vnto you. For first, it is by the benefit of Touching that we are conceiued and formed in the fertile Garden of our Mothers wombe. For our wise and prouident Nature ayming at Eternity, hath endued the partes of generation with a most exquisite sense of Touching, for the conseruation of the Species or kindes of creatures, so that the creatures beeing rauished with an incredible kinde of pleasure, doe more readily apply themselues to venereall embracements, (otherwise a thing filthy and abhominable) and endeauour the procreation of their owne kindes. VVhen the Infant in the wombe yet liueth onely a vegetatiue life, hee is first of all endued with the sense of Touching; whereby hee is cherished, nourished, and encreased, and is at length perfected; for so long as he is in the prison of the wombe, hee neither seeth, nor heareth, nor smelleth, nor tasteth any thing, but yet hath absolute necessity of the sense of Touching, that he may be able to auoyde imminent dangers.

The dignity of the sense of Touching.

No sense without Touching.

The touch doth first exist of all Senses.

Moreouer, this Sense is not only borne together with vs, but also which is more woor-

thy

thy of admiration, when all the other Senses perishing euen for the least perturbation of the minde and ceasing vsvngarded and prostituted vnto death, yet this like vnseparable and faithfull *Mates* doth attend vs vnto the last breath: whence *Aristotle* in the third Booke *De Anima*, cha. 13. Text. 67 writeth, *That if any Creature be deprived of this Sense it cannot possibly (saith he) that any creature should want this Sense, neyther if hee be a creature is it of absolute necessitie that hee haue any Sense besides this, (as if he should say) that this Sense is of the verie essence of the creature, and therefore other sensible obiects by their immoderate extremes, do onely corrupt their proper organ, but the excessiue qualities of tactile things do take away the life it selfe. As things cannot subsist without Touching, as Aristotle sayeth, who thought that neyther action nor passion nor any mixtion can bee without Touch, and therefore neyther can the mixt bodie be without it. For though these things without life do draw their nourishment out of the earth, yet they do it not indifferently and without choice of that which is more or lesse pleasant vnto them, if at least this kinde of reason or accord may be called a pleasure, when as indeede they haue not power to separate or distinguish that which is conuenient from that which is inconuenient.*

Touch is of necessitie the rest for commodity.

Plants cannot bee without Touch.

Furthermore, if we will stand to *Aristotles* determination, that there can no other sense subsist without Touching, then will it follow that this being taken away no sense can remaine. Now if the Senses be taken away, the whole family of Arts (which we said before did depend vpon their credit) must needs decay, nay you shall bring downe the Sunne it selfe out of the world. If any man doubt of this let him seriously survey all the Arts both Liberall and Mecanicall.

If you further demaund what vse this Sense doth affoord vnto Physicke, know that without it this Art would be verie defectiue, yea woulde so darken the eyes of Physitians, that they shall not be able to determine any thing certainly concerning the temperature of their Patients, of their Faculties or strength; but must of necessity grope vncertainlie in darke and palpable ignorance.

The Vse of Touching for Physick.

If you respect Morall Philosophie, this Sense will stand vs in great stead. For perceiuing and feeling the euils which ensue of vices it doth leade and encline vs vnto the way of vertue, yea it causeth vs to take pleasure therein, which pleasure the Epicures doubted not to account the *Summum bonum*. The like we might say of other Arts (which least our Discourse should be without end, we will with silence passe by, in all which Touching is not without his excellent vse.

His profite in morall Philosophie.

To conclude, if it be lawfull to transcend from these Earthly things vnto Celestiall, we will a little consider what vse this Touching hath in diuinity. Did not this Sense reduce S. *Thomas* wandring in by-wayes out of the heauenly light into the true way when he would try the presence of our Sauiour by this Sense, as it were contemning the vse of the rest? Did not the woman only by the Touch of the Hemme of Christs garment become sound and cured of her twelue yeares Flux of blood? And do not wee reade that eternall Prince of Physitians restored sight vnto the blind onely by the Touch of their eyes? And did hee not heale the woman sicke of a Feauer by Touching of her? Yea, and that which is beyond all admiration and farre exceedeth the vnderstanding and capacity of man, did hee not bring again from death vnto life the daughter of *Iairus* by taking her by the hand? And the Sonne of the widdowe ready to bee committed to the Earth onely by Touching the Coffin? O healthfull and sauing Touch, O searching Sense. But wee holde our handes, both Time & the Matter requires that we prosecute the remaining Senses in as few words as we can.

The profite of Touching in Diuinity.
Luke 17
Luke 18
Math. 9.
Luke 7

After the Sense of Touching we place the *Taste* in the second ranke. For besides, that one kinde of obiect, to wit, Earthy, is by Philosophers assigned as common to them both, it is as wel as the Touch not only commodious (for so are the other subsequent Senses) but also necessarie vnto the conseruation of the *Indiuiduum*, whence it is that manie commendations of the Touch do not vnfitly agree vnto this Taste. For seeing that Taste is the chiefe Sense in discerning of Sapors, as all men of vnderstanding acknowledge & experience it selfe confirmeth, it must needes followe that by the helpe thereof the bodye is nourished without danger, but when it failes the bodye perisheth and the whole Nature thereof goeth to nothing. For without it we cannot discerne of Sapours, nor iudge betwixt hurtfull things and healthfull, neyther betweene that which is pleasant and vnpleasant, but become inferiour not onely to brute beasts but also to plants, which do not confusedly

The praise of Tasting.

It is necessary for the Conseruatiō of the *Indiuiduum*.

fasedly and without choyce, attract any Aliment but that which is most agreeable to their Nature, and so conuert it into their owne substance.

But because the sense of Tasting doth participate with the Touch in the perception of sweetnesse and pleasantnesse as in many other things it doth: therefore I suppose the worth or excellency thereof is sufficiently declared in the commendation of the sense of Touching, so that we thinke it vnnecessary to vse any longer discourse thereof.

The prayse of Smelling.

We will now proceede to the sense of Smelling, the organ whereof seeing Nature hath placed in the middle of the other senses, we will therefore ascribe vnto it the middle place of honor betwixt the other senses. This Sense doth not only receiue the fragrant breath vapouring from odoriferous obiects and abiding in the ayre; but is besides a faithfull Taster of meats, it gouernes the mouth lest sometimes at vnwares we should swallow that which is hurtfull and distasting and so pollute the sweete Balsame of our life. And this instinct wee see in Dogs and Apes, who neuer snatch any thing into their mouths before they haue first made tryall thereof with their Nose.

Againe, by the strength of this sense many creatures do hunt out their liuing, and therefore the Kites follow after karkasses, hounds after Hares onely by their sauours: I say nothing of that excellent profit which it affords to the art of physick: for among other predictions in our art that is not the least which is taken from the Sauor of the patients excrements, whereby oftentimes we find out the cause, the kinde and the issue of the disease. Chirurgions also by the sauor or smell of a wound are able to iudge whether it be *Cacoetes*, that is, foule and ill an vntoward disposition or no. Adde hereto that by the smell wee attaine vnto the knowledg of simples, yea and of compositions, with what faculties and vertues they are endowed. From hence some haue concluded that all odoriferous things are hot and such like propositions.

The nose doth much beautifie the face.

The beauty that is added to the face of man by this organ of smelling (wee meane the Nose) is very great, I will giue you a pregnant instance therof in an example or two worth our remembrance. First, of a yong man who being adiudged to be hanged and the executioner at hand, a certaine maide suborned by his friends and quaintly dressed and set out, goes vnto the Iudges and makes supplication for his life, requiring him for her husband, well; she ouercame the Iudges: This done, the guilty yong man being set at liberty and comming from the gallowes vnto the maide attired and dressed in such costly ornaments, he presently cast his eye vppon her Nose which indeed was very deformed, and instantly cries out that he had rather haue beene hanged then freed vppon condition of vndergoing so deformed a choyce in his Matrimony. To this is that of *Horace* very answerable in *arte Poetica*.

Hunc ego me, si quid componere curem,
Non magis esse velim, quam prauo viuere Naso.
Should I indite, I had as liefe my Nose should stand awry.
As fairely to begin my worke, and patcht vp bungerly.

A History.

It also a very memorable example, (for we may mingle things thus holy with prophane) which we reade in our English Chronicles concerning one *Ebba* an Abbesse in a certaine Nunry, who cut of her own Nose & the Noses of her Nuns, that being so deformed they might auoyd the hateful lust of the Danes; taking it for granted that the Nose was the chief ornament of the face. And hence it was that in antient time, when they would put any man to great disgrace and ignominy, or disappoint them of all hope of attaining to any degree of honour, or the gouernement of a State; they cut off their Eares and Noses. Yea those which had such deformed Noses were neither admitted to any Priestly function nor Imperiall office.

So farre was it from them to account them worthy honour, who were destitute of this honorable Organ. Hence it was that the Prince of Poets, *Virgil* in the 6. of his *Aeneads* doth call the cutting of the Nose, *vulnus inhonestum*, a wound full of shame and reproch.

The Nose is necessary to life.

To these we may add that the Nose it necessary for our very life: in so much as Nature hath made it the instrument of Respiration, without which wee cannot liue one moment; for when the lungs needs more ayre then ordinary, wee perceiue the sides of the nosthrills to be moued sometimes not without violence.

But cutting short a whole troope of commendations wee will proceede vnto the Hearing, which no voyce, no not a riuer of eloquence is able to extoll with due prayses, if

we

we doe but contemplate the cunning, skill and diligence, which Nature hath vsed in the fabricke of this Organ, & more accurately intend how many winding inuolutions, burrows, holes, shels, dennes and darke caues like labyrinths shee hath prepared and furnished therein. The wonderful worke of the Eare.

I add further, that by the benefit hereof we attaine vnto the knowledge of all kindes of Sciences: in respect of which *Tully* doth equallize vs with the Gods. For these Arts are not ingrafted in vs by Nature, but to be obtayned otherwhere; for saith *Lactantius*, it is the propertie of God and not of man to haue *proper knowledge*, that is, arising out of himselfe. For this cause Nature hath by a diuine skill, made the eares open, that we might alwayes heare when learned men should teach & discourse learnedly, and lay vp in the Register of our minds that which we haue heard. And hence it was that *Constantinus* called Hearing the *doore of the minde*, because hereby we enter into the knowledge of other mens conceits, and whatsoeuer is concluded within, is as it were, vnlocked and layde open by this sense of hearing. Hearing is the gate of the mind.

But some will haply say that we may attaine vnto knowledge by reading without any helpe of hearing. We answer thus, that no man knowes how to reade which hath not first learned it by the meanes of Hearing. I will omit that which is found by experience, that a liuing and audible voyce doth better instruct then the silent reading of bookes, and that thing heard take a deeper impression in the minde then those which bee only read, and hence haply was *Plinie* brought to beleeue the Memory had his place in the lowest part of the Eare. Others there are who doe call Hearing the Sense of Memory, whence in their Hyerogliphickes they were woont to decipher and paynt Memory a hand holding an Eare; I also passe this by, that Hearing is after a sort the spy of the life and Manners, whereupon *Isocrates* desirous to try the towardnesse of a young man whom hee saw: *speake*, saith he, *that I may see*, And in holy Writ, *Iob* commaunds that *they bena their Eares and see*, accounting for certaine that the Hearing is the very meanes of discerning & iudging of mens minds. Hearing is the sense of memory.

But the desire I haue of breuity commands me to abridge my discourse. There remaines now of the externall senses onely Sight, which if it be not superiour and aboue the precedent senses, in dignity and honour, yet it is not a whit inferior to any of them. I say in dignity not in necessity: for if thereby we esteeme their prerogatiue, Sight must come behind, but if you respect the situation the conformation and the vse of this Organ, you may pronounce it more worthy by many degrees then any of the other. The prayse of Sight.

For their situation and place, it is in the most erected region and diuinest part; beside prouident Nature, hath on euery side bounded them with a concauous valley. They haue aspherical or round figure, which is no smal argument of their excellency. Seeing Nature is neuer wont to vse this noble figure, but when she endeuoures to effect some difficult or excellent worke. And for their vse we may thence easily inferre their preheminence, for beside that they watche for the safety of the creature, detecting things hurtfull, manifesting things profitable and laying open the differences of all things which are contained in this large Vniuerse, they bring vs vnto the knowledge of all things, so that they alone are fit and sufficient for inuention and discouery of arts, and which is the most all they do make manifest the great Creator of all things by those things which are visible, in the knowledge of whom doth our chiefe happinesse consist. They therefore which be destitute of these most diuine Organs may truly professe themselues miserable, seeing they remaining in perpetuall darkenesse cannot admire and contemplate the workes of Almighty God, nor behold the infinite variety of the kinds of things, neither yet dare euer affirme that they know any thing certainely, because of force they must beleeue that which the Heare related to them from others. From their place Figure. And vse. The miserable condition of the blind

That spirituall and most noble obiect of the Eye (I meane the light which is they Queene of all qualities) who doth not admire? and hence also coucludes the supremacy of this Sense; for the Eyes by the fruition of light doe distinguish life from death. Doth not *Hippocrates* the piller of Physicke, propound vnto vs most certaine signes of the passions of the mind by the Eyes? By these as by windowes we may pry into, and penetrate the deepest and most secret conuayances in the soule; and therefore *Alexander* not vnaduisedly sayd, that the Eyes were the *looking-glasse of the soule* whereupon some famous Phylosophers haue placed the chiefe seate of the soule in the Eyes. For these Eyes doe burne and shine, they twinckle, they winke, they are sorrowfull, they laugh, they admire, they loue, they lust, they flatter, and in one word they decipher and paint the image of the Mind with The obiect of the Eye most noble.

The Braine was made for the eye.

so artificiall a pencill, that they seeme to be a second soule; what should we say more? doth not *Galen* himselfe so highly extoll this Organ that hee thought the Braine was onely framed for their sake, a part so necessary and excellent that it makes vs verie much resemble the verie diuine Nature? And doth he not moreouer write, that the whole Head had the highest place in the body, onely because of the Eyes?

That it is a little world

A commendation doubtlesse wonderful, yet not more admyrable then competent & worthily deserued. For being a man of great and profound knowledge, he considered that the Eye was the true *Microcosme* or *Little world* in respect of their exact roundnesse and reuolutions: wherein besides the Membranes which I dare boldly call the seauen Spheres of Heauen, there be also the foure Elements found.

The foure Elements in the eie.

That Fire is there we will prooue in a conuenient time and place. That there is Aire who will denie which vnderstands with what plenty of spirits they do abound? As for Water, who doth not see it in the Eye doth prooue himselfe more blind then a beetle, all the other parts we will liken to the Earth.

The Apple & Rainbowe of the eie.

If you looke vpon the *Pupilla* or Apple, shall not you see shining Starres, yea rather a beaming Sun? Wherefore thou maist not vnfitly call the eies with the Poet, πύλας ἠελίοιο *The Gates of the Sunne*. Shall you not perceiue heere the diuers-coloured Rainbow framed with a seuen-fold circle? Shall ye not also obserue Haile and infinite other things, which do most fully declare the excellencie of this Sense by themselues without any additament of our Oration?

Agellius.

But seeing as *Agellius* saith, it is more blame-worthy to praise a thing slightly & coldlie, then earnestly to dispraise it, lest we should seeme to preiudice the worth of so excellent workes of Nature, we will heere make stay and addresse the small portion of our capacities vnto a more abstruse contemplation concerning the Nature, Manner, Number, Order, *Medium*, Obiect and Organs of all the Senses in Generall: afterward we wil descend vnto particulars.

QVEST. I. *What Sense is.*

The definitiō of Sense by *Aristotle.*

HAuing by way of Præface set foorth the Excellencie of the Senses, we are to proceede vnto a more full discourse of thē, which that we may the better accomplish, before we assay their particular handling, we will take a Taste of them in general, which may make way to the particulars, and may serue instead of a preamble, for the better vnderstanding of the Reader. First of all therefore, it is to be considered what *Sense* is. *Aristotle* in the 2. *de Anima* Texte. 12. saieth, *That Sense is that which can receiue sensible Formes without any matter*. But he seemeth to define sense in *potentia* only or *power*, which haply he would insinuate by the word *potest* or *Can*, especially because this cannot bee a true definition of *Sense* as it doth indeed and really *perceiue*; for a glasse also dooth receiue sensible formes without any materiall substance, & yet that perception is no sense. Whence *Iohan. Grami.* vpon the 127 Text of the second Booke *De Anima* saith, *To bee able to perceiue is not onely to receiue species or formes without the matter, but there is also requisite an Animall faculty which is not in all things that receiue the formes of sensible things without the matter*; as if he had saide, euen as it is in glasses.

Iohan. Grammaticus.

Alex. Aphrodis.

But the Philosopher would shew what manner of perception was necessary to Sense that it haue the acte of perception, and how the obiect ought to be disposed, except by the word *Perceiue* hee vnderstood *Discerning*, which Philosophers doe sometimes promiscuously vse, as we may gather out of *Alexander Aphrodisæus*, who vpon the 3. Booke of the Metaphysicks saith, *That Sense is an apprehension or discerning of present sensible things which are without the Sensorium or Organ*, and this is Sense in deede and acte, for wee are then saide to *perceiue* when we discerne the Obiects, which *Simplicius* vppon the 155. Text of the third Booke *De Anima* hath wel noted, defining Sense to be A knowledge or discerning stirred vppe in the Organ, first receyuing his acte from the sensible obiect: so that *Aristotle* by receyuing vnderstood nothing but the knowledge or discerning of the obiect. And the same definition he doth accurately and distinctly declare in the second Chapter and 138 Text of the third Booke *De Anima* where hee saith, *That the Instrument of euerie Sense doth receiue the sensible obiect without any matter, and therfore the Obiects be-*

Simplicius definition.

ings

ing remooued, there are in the Instruments of the Senses, Sensations and Imaginations. VVhat can be more euident? For how can the Sense of that obiect remaine in the Organ when the obiect is set aside, if it should onely receiue it without any acte of discerning? Are we not taught the contrarie in glasses? which because they onely receiue but knowe or discerne nothing, therefore presently as the obiect is remooued, they loose the Image. We will therefore out of this which hath bene saide gather a most cleare and absolute definition of Sense on this manner, That *Sense is a knowledge or discerning of the obiect receyued formally in the Organ.* A Sense is made with the knowledge of the Obiect.

QVEST. II. *What Action is, and how Action and vse do differ.*

Averrhoes verie worthily saieth in the first Booke *De Anima* and the 51. Text, that the first and chiefe consideration of Sense is, *Whether it bee to be accounted amongest the Actiue or Passiue vertues or Faculties of the soule*, that is, *whether it be accomplished by action or passion*, for he which is ignorant of this can neuer attaine to the perfect knowledge of the manner of Sensation. Considering therefore of this matter by the counsell of *Auerrhoes*, I haue heere determined for the more euident clearing of this question to declare what Action is, and also what Passion is.

Action therefore (which the Greekes call ἐνέργεια) *is a certaine actiue motion, proceeding from any thing fit for action for the obtaining of some thing.* It is called an *Actiue motion* by *Galen* in the first chapter of his 17 Booke *De vsu partium* and in manie other places, and that not without good reason, seeing that there is as well an Actiue motion as a Passiue motion. Manie call that an Actiue motion which is performed by the proper Nature of the thing, and of it selfe alone: and that Passiue which is caused by some externall agent. As for example: the walking of a creature is an Actiue motion in regard that it proceedeth from the proper & internall Facultie of the creature. But the casting of a Stone vpward is a Passiue motion, because it is performed by another & not by the proper internal principle. But because al motion made either by an internal or external agent, in relation to the patient is Passiue, and in relation to the Agent cause is Actiue, therfore certainly the casting of a Stone ought no lesse to be iudged an actiue motion then the walking of a creature, neither dooth this deserue lesse the name of a Passiue motion then that; for a creature in walking doth suffer, else wee must determine (which is more absurd) that there may be an action without passion. what action is. Why action is called an Actiue Motion. What actiue internall motion is.

But in my opinion the Logitians distinguishing actiue motion from passiue onelie in some respects and not indeed; haue more truly said, that Actiue motion is that which proceedeth from the agent for the effecting of some thing; and Passiue that which is receiued of the patient to make alteration in it: wherfore both action and passion being indeed one motion, as it commeth from the agent is an Action, and it is receiued of both Patient is a Passion. Action is relatiue. How Action and Passion do differ.

It is added in the aboue-named definition, *from any thing fit to performe action*, beecause euery thing doth not produce an action but that which hath a disposition and fitnesse for the performance of that action. This fitnesse or habitude vnto Action, called in Greeke εὐχρηστία or an agility of vsing, *Galen* in the first chapter of his 17. Booke *De vsu part:* calleth *Vse*, which signification doeth much differ from the word *Vse* taken for the acte of vsing or for the handling and exercising of an action, whereof *Cicero* speaketh in his *Topickes*. For *Galen* vnderstandeth by *Vse* an aptitude and disposition of the partes to performe an action, which parts if they were composed by Nature without this fitnes they could neuer performe any action, and so they should haue bene made in vaine. Diuers acceptions of vse.

This fitnesse in liuing Creatures consisteth in the temperature of the similar parts and the Legittimate conformation of the disimilar which dooth comprehend the Figure, Magnitude, Site and Number of them. Therefore this due Temperament and conformation, as it is fit for operation is vnderstood by the word Vse. Wherein this vse consisteth.

Moreouer, this Vse is two-fold, Principall and Assistant. I call that Principall, by the helpe whereof the Agent doth principally performe and exercise his operation. The Assistant I call that which is as a Handmayde, to helpe and further that the function be the better performed. Againe, this Principall is also two-folde. Not subordinate and subordinate. The Assisting vse is three-folde, first that which doth truly helpe, and that which Vse is twofold

doth conſerue or keepe; and thirdly, that which addeth ſome ornament or beauty to the Action.

The vſe not ſubordinate. The vſe ſubordinate.

That which is *not ſubordinate*, doth accompliſh a principall Action which is not inferiour to any other: But that is ſubordinate, for whoſe ſake the Agent vndertakes an action which is ſubordinate and preparatorie only. That Vſe or aptitude which doth only helpe and conſerue, may be ſeen in the lids and haires of the eye. And *Gal.* in the 13. Chap. of the 11. booke *de vſu partium*, doth plainely affirme, that the ornament and beauty of the action is to be referred vnto this helping or aſsiſting Aptitude.

Obiection.

But here ariſeth a difficulty, which is not ſlightly to be ouer-paſſed; for if thoſe things be true which we haue ſaide as we profeſſe them to be, it will neceſſarily follow that in liuing creatures euery organ ſhall haue ſome *vſe*, in as much as there is no part in the whole liuing body which is not fit and diſpoſed to operation after ſome of the fore-ſaide wayes, as it is taught in the firſt Chap. of the 17. booke *de vſu partium*. But *Galen* ſeemeth to differ from himſelfe and to contradict this doctrine in the 8. Chap. of his booke *de morb. diff.* Where he ſayeth, that ſome parts haue vſe onely and not action. Some haue both vſe and action, and others haue action onely and not vſe.

Solution.

But this knot may thus be vnlooſed and this contradiction reconciled, if we ſay; that to haue action and vſe is affirmed as well of that which doth helpe, as of that which doth principally apply it ſelfe vnto the performance of the action: So euery part of the body ſhall haue both action and vſe; but ſo, as to *haue action* doth ſignifie that aptitude by which the action is eſpecially performed, and to *haue vſe* that for whoſe ſake or by whoſe means the vſe and action is holpen and aſſiſted. The *action* therfore is principally from the parts, and the *vſe* they haue ouerplus, that is, that aptitude & diſpoſition whereby the principall action is either perfected or conſerued, or receiueth ſome additament of beautie and ornament.

QVEST. III. *Of the end of Action.*

What is the end of Action. The Action is leſſe worthy then his end.

THE laſt part of the definition was, *for the obtayning of any thing*, that the profit & end of the action might be intimated, which is the fruition of that where-vnto the action is directed. This is after the action in generation and conſtitution; but it is the firſt in dignity and excellencie, as *Galen* declareth in the 13. Chap. of the 11. booke *de vſu partium*. And as the fruition of any thing is the profit of the action, ſo the action is the profit of the vſe: ſo that (as *Galen* ſaith in the 1. chap. of his 17. *de vſu partium*) Thoſe things which haue an vſe for action, haue a double profit propounded to themſelues: that is, the action it ſelfe which is the profit of the vſe, and the fruition which is the profit of the action.

Queſtion.

Here doth ariſe a moſt intricate difficulty to be reſolued, for becauſe (ſaith *Galen* in the 8. and 16. Chapters of his firſt booke *de vſu partium*) There is required vnto the knowledge of the profit of the particulars, a procognition or fore-knowledge of the action, I thinke we muſt diſtinguiſh betwixt the action of the parts and the profit of them, and ſo it is falſe, that the action is the profit of the parts or of their aptitude.

Solution. To know the Action is two wayes vnderſtoode.

The action of the organs may be knowne two wayes, either vniuerſally and abſtracted from their organ, ſo that the production of the action may be made manifeſt without any conſideration of the organ: Or it may be knowne as it hath relation to the organ, that ſo it may be manifeſt by what meanes it proceeded from the organ, and what euery part did performe which is found in that organ. Now *Galen* affirming that the Profit of particular things cannot be vnderſtoode vnleſſe we accurately fore-know the action, doth vnderſtand by the name of profit the *Action*, and ſo would ſignifie, that the particular action ought to be vniuerſally & abſtractedly fore-knowne, that it may appeare by what meanes it comes from his organ, and that the function of euery particle which is found in that organ (though neuer ſo ſmall) may be known. And ſo it is not abſurd, that the action ſhould miniſter knowledge to it ſelfe, and ſhould be both more knowne and more obſcure then it ſelfe.

The difference betwixt vſe & profit.

The vſe therefore of the parts and their profit, doe differ as the words of *cauſe* and *effect*, though Vſe doe alſo ſignifie Profit, whereby it is manifeſt that the one is more large in his ſignification then the other.

Moreouer, that thing vnto the fruition of which the action doth ayme, is either ſeperated from the action ſo that the action ceaſing it is abandoned; or elſe it doeth only conſiſt

and

and hath his *being* in *Fieri*, that is, whilst it is in motion, & this is called in Latine *opus*, in Greeke τὰ ἔργον *actionis*, the *worke of the action*. *Galen* therefore in the 1. *de nat. fac.* saith well, that the worke is distinguished from the action and is an effect thereof as blood, flesh, a nerue or such like are the effects of the action of the Liuer and of the Seed. The difference of the worke and action.

Sometimes by the name of *worke* we vnderstand the Action, for concoction, sanguification and distribution, are certaine *actions* and yet the *workes* of Nature also; but wee must beware least we call all the workes of Nature Actions; for flesh, a nerue and bones are the workes of Nature, and yet no actions of Nature.

QVEST. IIII. *How manifold Action is.*

Galen in the first Chapter of his Booke *de vtilitate respirat.* deuideth the action of a liuing body into an vniuersall and a particular. I call that an vniuersall action which is perfected by the whole body as by his proper instrument, as are the life, which life *Aristotle* in the 10. of his Ethicks chapter third, and *Galen* in the place aboue quoted saye; is a kinde of action of the creature, as also are those foure which doe attend it: Retention, Concoction, Attraction and Expulsion. What is an vniuersall Action.

And a particular action I call that, which belongeth to some one part or organ, for the profite and behoofe of the whole body. But they are almost infinite, yet all allotted to their own proper parts, and so mutually conioyned and with such concord that they do all serue and helpe the operations of the whole, and do all conspire and as it were with one consent suffer together. What a particular Action is.

For great organs as the Head, the Breast, the *Abdomen* or Panch & the ioynts do with all their functions immediatly serue the whole body. And the lesser which are parts of these are also referred to the action of the whole. As the Eye whose action being wholly destinated to the safety of the creature is Sight, which Nature by the chrystaline humor doth exercise; all the other parts doe concur vnto the constitution thereof, and serue either as causes without which vision cannot be made as the opticke nerues doe; or as a cause of the better performance of this Sense as the muscles and coates; or lastly as conseruing and defending causes, as the Eye-lids and the Eye-browes. The consent of the parts.

Some doe subdiuide a particular action into a common or publique and into a proper or priuate action; & they call that common which is referred vnto the vse of the whole and not of any priuate part onely, as are those operations called Animal, to wit, going, apprehension, Vision, Hearing, Smelling, Tasting, Touching, Imagination, Ratiocination & Memory. Amongst the Natural operations, Chylification or the action of the stomack changing the meate into Chylus, Sangnification, Expulsion of the excrements, the sucking of the Vrine out of the veines, attraction of seede, the conformation of the Infant, with many other. What a common Action is

They call that a proper action, which is addicted vnto one onely part, such as they affirme to be Retention, Concoction, Attraction & Expulsion, which I haue comprehended in the number of vniuersall actions, but they say they belong vnto the proper vse of the part. What a proper Action is.

But this manner of distinguishing is not to be in euery respect admitted in my opinion, because it doth much rather ingender a confusion then further our vnderstanding, in that they confound a proper and particular action with an vniuersall. For why should that action which pertaines to the whole and is vniuersall and common to all the parts, be called proper and priuate? How shall it bee allotted to one onely part? If that which they call common be assigned to one organ, how is it said to be common? Yet if any man shall say, that it is called common by accident because it tendes to a publique and common good, him I will not gaine say. But it will be obiected, that that which is called by them a proper and priuate action, will by the Physitians neuer be admitted to be vniuersall and an action of the whole body, and of all the parts thereof. Obiection.

For although attraction, retention, concoction, expulsion, do agree to the whole and to all the parts, yet they be so appropriated to their seuerall parts, that they seeme to be proper vnto euery particular, because that the seuerall parts doe conueniently exercise them by their owne nature. Solution.

But I thinke, that attraction being restrayned to some certaine humour, doth not enduce the propriety of attraction, but of that which is attracted by it.

Now that which is drawne, and the attraction it selfe doe differ. So a bone doth attract, yet not as it is a bone, but as it doth participate of life and the function of the whole, yet it doth attract a proper iuyce as it is such a part and no other. But be it so, that attraction and other Naturall functions doe belong and be ascribed to a bone, a gristle, a membrane,

Membrane & other ſuch like parts as proper vnto them, in regard that they all do properly and in their owne nature conueniently exerciſe them: yet ſhall it follow that euery part of the bone and portion of a griſtle or ligament ſhall performe a proper action. One and the ſame iuyce is common to all the particles of the ſame ſimilar part. Wherefore this ſubdiuiſion of a particular action in my opinion is not allowable.

Some parts haue a double action ſome onely one.

But I conclude from that which hath bene ſayd, that ſome parts do performe a double office, namely one common to all other parts, another proper which is committed to them and to no other parts; and yet tending to the vſe of the whole. And this office or function is three fold, to wit, Animall, Vitall and Naturall. But what euery one of theſe is and how manifold we haue before declared, and therefore they are here onely preſuppoſed.

What action is manifeſt of it ſelfe and obſcure of it ſelfe.

Moreouer ſome actions be manifeſt by themſelues yet their Organ is obſcure and hidden, others be cleare and manifeſt both of themſelues and in reſpect of their Organ, others be obſcure both in themſelues and in their Organ. I call that action manifeſt of it ſelfe which is ſenſible and may be iudged of by the Senſe; and that obſcure of it ſelf which doth not appeare but from thoſe *workes* which proceed from it. I call alſo that manifeſt by the means of his Orgã, whoſe organ doth preſently appeare, & in this without all doubt do al conſent: but I account that obſcure in regard of his organ, when the action doth appeare, yet the Organ doth not preſently be wray it ſelf without much ſtudy, & diſcorſe of the mind which is held of ſome only for probable where about many do diſſent. Thoſe which be manifeſt both in thẽſelues & by their Organs be theſe; vociferation, pulſation, reſpiration, the locall motion of the parts, expulſion of excrements, the expulſion of vrine the emiſſion of the ſeed, &c. In reſpect of both, with *Galen* in the 8. & 16. chap. of his 1. book *de vſu partiũ* are the apprehenſion of the hand, the walking of thee feete, chewing, viſion, hearing, &c.

Finally, theſe are eſteemed obſcure in reſpect of both; the tranſmiſſion of the blood, the carrying and recarryinge of the ſpirits, the generations of animall ſpirits, he preduction of vitall, the ſucking of vrine out of blood, chylification, ſanguification, and the generation of ſeede.

QVEST. V. *That Senſe is not a pure paſſion.*

Whether the obiect or the organ doe worke in the ſenſe.

SEeing therefore that vnto an action there doe neceſſarily concurre an agent and a patient; the *agent* for to worke, and the *patient* to be a fit ſubiect for the *agent* and to receiue the action; it may now be demanded whether the action proceede from the Organ vnto the ſenſible obiect, or from the obiect vnto the Organ, and whether this be to bee accounted an *agent* the other a *patient*, or on the contrary. Concerning this poynt there bee diuers opinions of Authours, for ſome maintaine Senſe to be paſſiue, others actiue, others both actiue & paſſiue. *Ariſtotle* doth contend for thoſe which would haue Senſe to bee paſſiue, eſpecially in the 118. text of his 2. book *de Anima*, wherein expreſſe termes he affirmeth that to *perceiue* is a kind of ſuffering, & alſo calleth the obiect an *agent*: again in the 51. text of the ſame booke, he ſaith, that Senſation hapneth in that which is moued and ſuffereth. And he ſeemes moſt exactly to demonſtrate it in the 12. text of his 7. booke of Phyſicks, ſaying, *That the ſenſes are altered: for they ſuffer, and their action is a motion through a body which ſuffers in the Senſation* So that it may be gathered out of theſe places of *Ariſtotle* that Senſe is made paſſiuely, that is, that the act of Senſation is not made by the Senſe, but by the ſenſible obiect, and that the ſenſe doth nothing elſe but receiue the ſpecies from the thing obiected and ſuffer from it: but this opinion though it be approued of many and be held for *Ariſtotles*, yet it is neither agreeable to *Ariſtotle* nor to the truth. That the places cited out of *Ariſtotle* doe not confirme this we will proue by and by, when as by many reaſons we ſhall haue demonſtrated how farre diſtant it is from the truth. For firſt, if the Senſe ſhould onely concurre paſſiuely vnto ſenſation, that is, if ſenſation were onely a reception of the ſenſible ſpecies, then we muſt needes euen when we are aſleepe heare, ſmell, & ſee, ſeeing therfore; that although when we are a ſleepe ſome certaine noyſes or ſounds be carryed to our eares, and ſome odors do ſtrike the noſthrils and colours (if ſo be we ſleep with our eyes open as ſome doe) bee preſented to our eyes, yet we doe not heare or ſmell, or ſee; it will follow neceſſarily that ſomething elſe muſt concurre vnto ſenſation beſide a ſimple reception of the ſenſible ſpecies. Add further, that though wee receiue a viſible thing into our Eyes, and a ſound into our Eares, yet we neither ſee nor heare when wee are intent another way, or haue our vnderſtanding exerciſed in greater matters. Wherefore there muſt be ſome part of the mind preſent in ſenſation; and hence it is that wee ſometimes ſeeke a very ſmall thing and yet ſee it not though we be very neare it, and though it be already re-

Their reaſon which ſay ſenſe doth ſuffer.

That opinion diſproued. 1. Reaſon.

2. Reaſon.

and

ceiued into the eye: Surely this is an argument most euident that the mind must be applied to that thing which we would see, and that something more is required to Sense then the bare reception of the species, for else a glasse might also *perceiue* in as much as it doth receiue the images. Moreouer, if onely the reception of species were a sensation, all action should proceede from the sensible species, & that species should be so prompt vnto action that it would worke euery where and vpon euery subiect, and so would make sense; euen as heate doth make hot euery where and euery thing; but this is impossible, for who euer affirmed that sense was made out of his proper Organ.

Sensation is not therefore an action onely of the sensible species, neither was it *Aristoles* opinion, for in the 37. text of his second booke *de Anima*, hee teacheth the plaine contrary, and affirmeth manifestly, that the soule is the efficient cause of sensation, and therefore not the sensible thing, and in the ninth chapter of the ninthbooke of his *Metaph.* he prooues that vision is an action of the sight. And what can be more manifest then that which he expresseth in the second chapter of his book *de sensu & sensili* where he reprooueth *Democritus* for saying that vision was an operation of the obiect: and propounding the conformity of the similitude which the sensible thing hath with the Organ, hee saith, *the sensible thing causeth the sense to worke*, as if he should say, *the obiect doth excite and prouoke the sense vnto action.* The poynt is as cleare as the light, but yet what shall wee answer to those contrary places, quoted euen now out of *Aristotle*, for it seemeth by them to bee plainly affirmed that sense is passiue. But I deferre the reconciliation of this contradiction till the seuenth Question, where you shall haue also *Placentinus* his resolution.

Arist. thought the contrary.

QVEST. VI. *That Sense is not a simple action.*

THat Sensation is not a meere passion, is plaine from that which hath beene said. Now it is to bee considered, whether it ought to bee called an Action, that is, whether Sense doe *perceiue* onely by doing or acting. And that setting aside all digressions, I may come to the matter; I say. Seeing euery Agent in doing and acting doth also suffer againe, it followes necessarily, that the Sense doth continualle suffer something from the sensible Obiect: for there is no man ignorant that to the effecting of Sensation it is necessary that the Sense be conuerted into the nature of the sensible thing, but it cannot be conuerted but by alteration, because things of an vnlike nature cannot be made of one nature, except the one of them be changed, but the Sense and Obiect be of an vnlike condition. And this is it where-vpon *Aristotle* so oft beateth, that the Sense is potentially that which the sensible thing is actually and really, and except the Sense doe passe into the nature of the organ Sensation cannot be performed. Whence it followeth, that the sensible thing doth alter the Sense and turnes it into it owne nature, and therefore *Aristole* often times calls Sense an alteration, for so Sense is made. Now if the Sense be altered and changed by the Obiect, it is necessary that it must suffer, because the sensible thing when it altereth the Sense worketh vpon it. Hence it is more then manifest that Sense is not perfected by a simple Action.

Passion is necessary to Sense.

The sense & the obiect be vnlike.

The obiect must alter the sense.

QVEST. VII. *Placentinus his opinion.*

IF therefore Sense be perfected, neither by action nor passion, how shall wee say that it is performed? I answere, that it is absolued and perfected, neither by action onely nor by passion onely but by both together, that is both by action and passion. That action is requisite vnto Sense, is prooued by the Negatiue part before refuted. We will adde some arguments wherewith we are purposed for the present to confirme the affirmatiue. And first, if Sense should be made without acting, it would follow, that the vegetatiue faculty should be more noble then the sensatiue, because that to *doe* is more noble then to *suffer*, but no mã doubts that the faculties of the vegetatiue soule are Actiue, wherefore least we should fall into an absurdity vnheard of and monstrous, wee must graunt that the faculties of the sensatiue soule are also Actiue. Furthermore, if the Senses should not *worke*, they were in vaine giuen vs by nature, because the organ onely would haue sufficed vs for passion. Againe, if the Sense were onely passiue, neither could the sight see, nor the hearing heare, nor the smell performe his owne function, neither were any such like predications true of the other Senses, because these predications doe intimate that the Sense doth produce out of

Sense is absolued by action and passion together

That action is requisite. Reason.

it

What life is.

it ſelfe an act of Senſation. Fourthly, Senſation is an operation of life, and therefore proceedeth from an internall and actiue originall of motion, for life is *an internall motion, performed by that which liueth.* Vnleſſe therefore you graunt that Senſation is an Action, it cannot be an operation of life. Laſtly, Senſation is a ſecond act, and the ſenſatiue ſoule is a firſt act: for to *perceiue* is an operation of the ſenſatiue ſoule, and therefore *Ariſtotle* beſide many other places, affirmeth in the 7. Chapter, and the 127. Text of the 2. booke *de anima*, that to *perceiue* is ſomething more then the ſuffering of the Senſe, whereby it is manifeſt that Senſe is an Action.

Senſe is an operation of the ſenſatiue Soule.

Queſtion.

How it is a Paſsion hath beene before declared. But it may here be doubted by what meanes two Agents can concur vnto one Act of Senſation, and this doubt is worthy the noting: for if the ſenſible Species doe make Senſation, and the ſenſatiue faculty doe together there-with perfect the ſame Action, there muſt needes bee two immediate effectiue or operatiue Principles of one and the ſame Action; which is impoſsible: becauſe that Senſe (witneſſe *Ariſtotle* in the 9. Chap. of the 9. booke of his *Meteph*) is an *iſſuing* Action, now an iſſuing & ſimple Action cannot proceede from two immediate Agents really diſtinct. Againe, it is impoſsible that an iſſuing Action ſhould proceede from an outward originall, but from that where-out it ought to ariſe and to bee perfected. For the enodation and reſolution of theſe difficulties, and the explication of a double truth, we muſt know that Senſe is many wayes to be vnderſtood.

Senſe is an immanent Action.

Solution.

Firſt, as it is a reception of the Species, and ſo it is a Paſsion, for in that reſpect it ſuffers of the Obiect. And of this did *Ariſtotle* vnderſtand that where he ſaith, that *to perceiue is a kinde of paſsion or ſuffering.*

Secondly, as it is a diſcerning and knowing of the Obiect by the Species, receiued into the Senſe, and ſo it is an Action, for ſo the faculty doth worke vpon the Species, and ſo the ſight doth ſee, and the hearing heare, and ſo of the reſt; and ſo is *Ariſtotle* to be vnderſtood, when he ſaith that the Senſes be Actiue.

Thirdly and laſtly, Senſe is taken for both together; to wit, for an Action and Paſsion, when as the whole Senſation that is the perfect act of Senſe is vnderſtoode: for firſt, vnto the perfection of Senſation, there is neede of Paſsion or an alteration of the Organ, from whence afterward followes the Action of the faculty, which *Ariſtotle* did excellently note, where he ſaith, that Senſation begins at the Inſtrument and body, and is determined in the Soule: as if he ſhould ſay the alteration of the Organ and the diſcerning of the ſenſatiue faculty doe accompliſh a perfect Senſation. The ſame alſo muſt wee vnderſtand when he ſaith, that to *perceiue* is a ſecond Act, & the ſenſitiue Soule a firſt Act, becauſe to *perceiue* is the operation of the ſenſatiue Soule. Thus therefore may the difficulties propounded be eaſily reſolued, and ſo *Ariſtotle* redeemed from contradiction.

Senſe begins in the Body, and ends in the Soule.

QVEST. VIII. *How the faculty is wrought in the Senſe.*

Queſtion.

Senſe is no alteration, but a knowledge of the alteration.

SEeing that (as *Galen* in the 6. Chapter of his ſecond booke *de Placitis* witneſſeth) Senſe is not an alteration, but a *diſcerning* or knowing of the alteration; becauſe the ſenſatiue faculty is not affected with the Obiect, but onely the Organ: it may therefore heere worthily be doubted, how the faculty can attayne to the knowledge of the Obiect, ſeeing it ſuffereth nothing from it, neither doth the Obiect *Act* before the faculty *perceiue*. For the Action of the ſenſatiue faculty is a knowing and diiudication of the ſenſible thing: but it ſeemeth not to be poſsible, that the ſenſatiue faculty can come to the knowledge of the Obiect, except that either the faculty be ſome way affected by the Obiect, or the Obiect by the faculty, but neither of theſe can be. For firſt, the Obiect cannot work vpon the faculty, becauſe an incorporeall thing, is not affected by that which is corporeall. But the faculty is incorporeall, and the Obiect corporeall. Beſide, the Soule is not capable of Paſsion, and therefore neither are her faculties capable. Neither can the ſenſatiue faculty alter or change the Obiect. And this is playne, as by many other reaſons, ſo alſo becauſe her ſole and onely Action is Senſation. I ſay therefore, how comes it to the knowledge of his Obiect? And what is the efficient cauſe of the diiudication or iudgement, which the faculty giues of the ſenſible Obiect, which we perceiue to ariſe from the motion of the Organ.

The Obiect cannot worke vpon the faculty.

The faculty cãnot change the Obiect.

Solution.

The Organ is chang d by it ſelfe, the faculty as it is in the Organ.

I anſwere: that the ſenſatiue faculty doth ſuffer, and is changed by the Obiect, not by it ſelfe but by accident, to wit, as the organ whoſe formall part & Eſſence the faculty is, is changed by it. For ſeeing the faculty is as it were the *idea* or *forme* from whence the

Action

Action of the organ doth proceede, when this corporeall Inſtrument is changed by the ſenſible obiect, it remaineth that the Faculty it ſelfe (which together with his ſenſible inſtrument doth grow vp into one bodie, and do both conſpire vnto the ſame action) is altered by accident and doth perceiue the alteration of his Organ. For all Organs of ſenſation do ſuffer by reaſon of their bodye, but in reſpect of their Senſatiue Faculty they performe an Acte.

Paſsion doth affect the Faculty as it depends vpon the organ; Action is the diiudication or iudgement, which is the office of the ſenſitiue Faculty, or of the whole organ in reſpect of that Faculty wherewith it is endowed: not that the Faculty it ſelfe is altered or doth ſuffer, but becauſe it *Perceyueth* the alteration of the organ.

QVEST. IX. *Whether the knowledge of the ſenſible thing be perfected in the Organ.*

Although it be made manifeſt by that which hath beene ſaide, that the proper action of the Senſatiue Faculty is the diiudication of the ſenſible thing, yet there ſeemeth to be ſome difficulty behinde. for, if the Faculty doe make this iudgement of the obiect in the *ſenſorium* or Organ, then thoſe which ſleepe with open eies ſhould alſo ſee becauſe the colour doth alter the Organ. In like maner a ſound might be heard, odours ſmelt, and any tactile quality might be felt by vs, ſeeing that the Organ is altred by the Obiect, and yet when wee are aſleepe we neither do ſee, nor heare, nor *Perceyue* with anie other Senſe except the Obiects be verie vehement. Haue therefore the Poets truly faigned that ſleepe is the brother of death, becauſe it dooth depriue vs of all our ſenſe, yea of our verie Touch; inſomuch that it ſeemeth to extinguiſh the creature & bereaue it not of Senſe onely, but of life alſo? Or elſe do we *perceyue* while we ſleepe, and know not that we haue Senſe? The firſt cannot be, for although ſleepe haue a great correſpondencie and affinitie with death, yet it doth not depriue the creature of ſenſe. For theſe things do concurre vnto Senſe: a conuenient obiect, an organ fitly diſpoſed, the alteration of the ſame organ and a ſenſitiue Facultie, al which things we haue euen when we ſleepe.

The poets ſay ſleepe is the brother of death. Diſproued.

What things do concur to Senſe.

Firſt, the Obiect is preſent, for colour though we be aſleepe, yet is it the Obiect of ſight, and continueth to be actuallie an obiect as long as it is illuminated with the light of a Candle or with the daylight; ſo alſo it is with ſounds, odours and other obiects of the Senſes. The Organ is alſo preſent and ſo is the alteration of the ſame; ſeeing there is nothing which can hinder the operation of the ſenſible ſpecies vpon the organ, or the alteration of the ſame. Neither is the Faculty wanting: for if the Facultie of one ſenſe ſhould faile all the Senſes would be forfeited, and ſo of a liuing creature ſhould be made a Plant depriued of ſenſe and motion.

Moreouer, though we ſleepe, yet our organs liue and they liue by the Soule. If therefore the ſoule with all her powers and faculties be wholy in the whole, and wholie in euerie part, it muſt needs be that if the creature liue the Faculties of Senſe muſt bee preſent in euerie place where the Soule is. But the ſoule is found in the organs of ſenſes, yea euen when we are aſleepe; except you will ſay that the Soule dies when wee fall aſleepe. Wherefore it neceſſarily followes that the Faculty of Senſe is there alſo preſent in the organ.

The ſoul with her Faculty is wholie in the whole.

Seeing therefore in ſleepe we haue the obiect actuallie prepared vnto ſenſation, ſeeing alſo the organ fitly diſpoſed is not wanting, and the iudging Faculty at hande, and that nothing more is required vnto perfect ſenſe; it is not to be doubted but that Senſation may be abſolued in the organ and iudgement alſo giuen of the obiect euen when we are faſt aſleepe. But the reaſon why we do not perceyue this Senſation, is, not becauſe we haue no ſenſe at all, but becauſe we know not that we haue Senſe.

Wee haue ſence in ſleep but knowe it not.

QVEST. X. *That by our outward Senſes we doe not know that wee haue Senſe.*

That wee doe *perceiue* by the Organs of our Senſes is euident enough by that which hath bene ſaide, but it is doubtfull and vncertaine how wee ſhall know that we haue Senſe, ſeeing that this knowledge is not gathered from the externall Senſes: for whatſoeuer is *perceiued* by them muſt be their proper obiect, but Senſation is the obiect of no externall Senſe.

Moreouer

Moreouer the externall Senses know nothing but externall things; but the acknowledgement of Sensation is no externall but an internall thing: wherefore it cannot be *perceiued* by the externall Senses. Thirdly, if together and with the same Sense we should *perceiue* and take knowledge of this perception, it woulde then necessarilie followe, that the acte of *perceiuing*, and the obiect of Sense should bee one and the same thing, which how absurd it is I referre me to any man to esteeme. Lastly, we do not at the same time Perceiue and Iudge of that which we haue perceiued, but somwhat after the acte of Sensation we know that we did Perceiue: a manifest argument that the one is diuersed from the other, and that with one Sense we do perceiue, and with another that we did perceiue. But this may especially hence be conuinced, that blinde men though they do not see, yet they perceiue that they do not See: seeing therefore the Organes of their sight are vnfit for vision, it doth necessarily follow that it is by another Sense that they perceiue themselues not to see. Now if it be by another Sense that we know that we do not perceiue, surely it is another Sense also by which we know, that we do perceiue.

We know not that we perceiue by Vnderstãding nor reason.

QVEST. XI. *Whence it is that we perceiue that we haue Sense.*

IF therefore none of the external Senses do performe this function, what can it be? Is it the worke of our vnderstanding or of our Reason? No: for this action is common to brute Beasts which be destitute of reason. For they know when they do not See, or Heare, or Smell and so in the rest. And that they know so much may easily bee gathered by their opening of their eies when they be shut, and pricking vp their Eares when they would See or Heare. Neither needs we wonder heereat, for they are enriched with some Functions that come nerer vnto reason it selfe, as I might easily proove by many instances of diuers creatures out of *Aristotle* and *Pliny* and other Historians if I thought it pertinent to this place. Seeing therefore vnreasonable creatures do know when they *perceiue*, that is, haue vse of their Sences, it followeth necessarilie, that that knowledge is not a worke of Reason.

It is no worke of the phãtisy

Neyther is it any worke of the Phantasie, in regard that it worketh after the act of *perceiuing* when the obiect is not present, but this Sence ought to iudge, at least then when we haue vse of Sense, that we doe vse it, and after Sensation to doe nothing, whence *Aristotle* in the 136 Text of the third Booke *de anima* handling this matter affirmeth, that this is done continually in the first Sense. And this Sense is the common Sense, so called becaus it is proper to no one Sense, but is equally common to all; for Nature hath alwayes endeuoured that shee may bring a multitude into an vnity so much as possibly may be: wherefore she hath ioyned in one common sence al the outward Senses, whereinto as lines going from the circumference into the center they may determine: & this hath the Philosopher verie elegantly declared in the 30. Text of his third Booke *De Anima*, and calleth this Common Sence the meane or middle betweene the external Senses, considering them as the Circumference and this as the Center. This is that Sence by which we know that we Heare & See and perform the functions of the other Senses: this is it which being bound in our sleep maketh vs ignorant of our Sensation: this is it which except it be present all the other Senses are vnprofitable: this is it which offereth to the Phansie the species which the outward Senses haue perceiued, and the phantasmes to the vnderstanding. In a word, this is it without which neither the externall nor internall Senses, nor the principall Faculties of the Soule could consist entire and absolute.

We know that we perceyue by the Common Sense.

QVEST. XII. *Of the Number of the Senses.*

That there be fiue Senses.

IT is receiued of all men that the Senses be fiue in number, but especially of *Aristotle* in the first chapter and 128 Text of his first Book *De Anima*, who sayth, that beside Sight, Hearing, Smelling, Tasting and Touching there can be no other Sense assigned. And this is also confirmed by reason, becaus there be onely fiue Obiects; Colours, Sounds, Odors, Sapors and Tactile qualities: if therefore there can be found no other proper obiect beside these fiue (I meane of externall obiects) it doth necessarily follow that there is no other Sence beside these; so also because these fiue mentioned seuerall Obiects are so proper vnto their seuerall Senses, that none of them is iudged of but by his owne proper Sence: I say it followes hence that there are no fewer Sences then fiue, because the Obiects are full out fiue.

That there be fiue propper Obiects of the Senses.

The number of the Senses.

Furthermore, this number of fiue Sences is also confirmed by the number of the Elements, for *Aristotle* in the end of the second Chapter of his Booke *De Sensu & Sensili* saith,

ſaith, that euerie organ is aſsigned to a particular Element, namely, the Eye to the water, the Hearing to the Aire, the Smelling to the Fire, the Touching to the Earth, and Taſting, becauſe of his neere affinitie to Touching is reſembled vnto the ſame Element.

Obiection. Solution

Neither doth that which may be obiected any way infringe or impeach this opinion, to wit, becauſe there is one onely Senſatiue Faculty therefore that there ſhould bee but one ſenſe: for the reaſon why the eie diſcerneth colours, the Eare iudgeth of ſoundes, the Noſe perceiueth ſauours, is not from the Faculty but from the temperature of the Organ; for the Foote alſo would ſee if it were endued with a temperament conuenient for the diſcerning of colours. That they haue Senſe, the Organs haue it from the Faculty; but that they perceiue rather this then that Obiect, they obraine it not from the Faculty but from the temperament of their Organ. Wherefore, whereas the Eye doth diſcerne of Colours; the Eare of Sounde and the Noſe of odours, it is not becauſe there is a certaine Viſiue, an Auditory and odoratorie or Smelling Faculty, but becauſe one and the ſame faculty carrying it ſelfe in euerie Organ after the ſame manner, doth diuerſlie proceede into acte, according to the diuers temper of the diuers Organs.

QVEST. XIII. *Of the order of the Senſes.*

HAuing thus determined the number of the Senſes: it followeth in the next place that we ſpeake ſomething of the order of them, to wit, whether wee ought to begin with the ſight as *Ariſtotle* and almoſt all Philoſophers do, or with the Touch which is a contrarie way wherein Phyſitians & Anatomiſts do walke, and theſe be the two contrary Sects concerning this matter of order, for none euer made doubt about the interruption or breaking off the order; but how manie Authors ſoeuer there be they haue either placed Sight in the firſt place, Hearing in the Second, Smelling in the third, Taſting in the fourth, and Touching in the Fift: or elſe on the contrarie haue put Touching in the firſt ranke, Taſting in the ſecond, Smelling in the third, Hearing in the fourth, and Seeing in the fift and laſt place.

Senſes to bee placed according to the order of the Elements.

As concerning the firſt, it is the opinion of the Philoſophers and of *Ariſtotle* eſpecially, who, both in the ſecond Booke *de Anima* and in the 2. 3. and 5. chapters of his Booke *De Senſ. & Senſ.* doth ranke them in this order. Moreouer this aſſertion ſeemeth to bee grounded vpon reaſon, becauſe this is the order of the Elements which do concurre for a *Meane*, or other helpe to the Senſes; ſo that euerie ſenſe in reſpect of that Element vnto which it is appropriated, ought thus to be placed, and according thereto ſhould their order and frame ariſe.

The ſight is fierie.

Sight is then the firſt of all the Senſes, becauſe Fire hath the firſt place among the Elements, for ſight is fiery, both in regard of the Senſe; for it hath an ingenite or inbred fire, as alſo by reaſon of the ſenſible thing, for except there were light which proceedeth from a fiery bodie, there would be no viſion.

The Hearing is aiery.

The Hearing is the ſecond becauſe it is aiery, for aire occupieth the ſecond place: and the Hearing is airy both in reſpect of the Senſe becauſe it hath an inbred aire, and in reſpect of the Obiect, becauſe the Sound is formed in the aire, ſo that it is of the Eſſence thereof.

Smelling is vaporous.

Smelling is put in the third place, becauſe as it is the middle betweene the other Senſes, ſo it is appropriated to an Element (if I may ſo ſay) diſpoſed in the middeſt of the reſt. For that which is a *Meane* betweene the Nature of Water and aire as *Galen* doth well witneſſe in the ſecond chapter of his Booke *De Odor. Inſtrum.* falleth vnder the Sence of Smelling; becauſe that which is neyther ſo thin or rare as aire, nor ſo craſſe and thicke as water may well be concluded vnder the name of a Vapour. Now that Smelling is vaporous both in reſpect of the Sence it ſelfe and of the thing ſenſible, wee may haue occaſion to prooue heereafter.

The Taſt waterie.

The Taſte deſerues the fourth place, becauſe Water ſucceedeth Aire, and to water this Sence is referred, as wel becauſe of the Communion of the Senſes, as alſo in regard of the eſſence of the obiect.

The Touch earthy.

The laſt place belongs to the Touch, becauſe the earth is in the laſt and loweſt place, of whoſe nature and quality this ſenſe of Touching doth participate.

QVEST. XIIII. *A conformation of the order of the Senſes.*

The order of the ſenſes proued by the conſtitutions of the organs.

THat the Senſes ought to be thus continuated among themſelues and propounded in this order, the conſtitution and conformation of the Organs doe giue vs ſufficient proofe: for the proper Inſtrument of ſight is vayled with a very denſe and thicke couer, that of the Hearing is more rare, that of the Smell yet thinner then them both, which *Galen* in the 6. Chapter of his 8. booke *de vſu partium*, hath very well obſerued, where ſpeaking of this Senſe, hee ſaith, *If the couer were ſo framed, that it might be no hinderance to the Senſe, then it ought to be ſo much more rare then that of hearing, by how much the obiect hereof is of more craſſe parts then that of the eare.* The couer of the Taſte is not onely more rare, but it is altogether ſpongie, as we haue ſhewed before in the membrane of the Tongue. Laſtly, the couer of the Touch is moſt rare of all.

Parts.

And by the tenuity & craſſenes of the obiects.

This order is moreouer confirmed by the qualities of the Obiects, for the Obiect of the Sight is the thinneſt & fineſt of all the reſt, yea after a ſort ſpiritual & not corporeal. That of the hearing is more craſſe, and the Obiect of Smell yet more craſſe and thicke then either of them: where-vpon *Galen* in the aboue-named place witneſſeth, that the Obiect of the Smell is of more groſſe parts then that of the Hearing: for ſaith hee, *by how much the ayre is exceeded by the light in the tenuity of their parts, by ſo much is the vapour ſurpaſſed by the Ayre.* The Obiect of Taſte is much more craſſe then the former. But the Touch being earthie, muſt needes bee the moſt craſſe of all. Finally, this muſt needes bee the order of the Senſes, in reſpect of the *medium* or *meane*; for the Sight aboue all hath neede of a meane, but Hearing hath leſſe neede, and the Smell leſſe then it. Taſting is as ſome thinke without any meane at all, but eſpecially the Touch as wee haue partly prooued already, and haply it will againe fall vnder our diſcourſe.

And by the neceſsity of the *medium* or meane.

Laſtly, the Poſition of the Inſtruments are a confirmation of this order: for the organ of Sight is placed without, but the organ of the Eare is a little more inner, and the inſtrument of Smelling more inward then them both, that of the Taſte is yet more hidden, and the Inſtrument of Touching is called by *Ariſtotle* τὸ ἐντὸς ὄν, that is, *exiſting within.* By theſe demonſtrations therefore is this continuation and order of the Senſes ſufficiently confirmed, to wit, becauſe euery one ought to be placed in this aſsigned rank. The Sight and Touch be the extremes becauſe they are moſt diſtant one from another, by reaſon that the obiect of Touch is corporeall and materiall, and the obiect of the Sight incorporall and ſpirituall; the Organ of Touch is placed within, but the Organ of Sight without; the Organ of Touch is couered with a moſt rare and thin vaile that of the Sight with a moſt denſe and thicke couer, becauſe Sight vſeth a Meane, but Touch none at all. Laſtly, the Touch is earthy and the Sight is fiery. The Hearing and Taſting are leſſe diſtant one from another, and the Smell is equally affected to all, and therefore by good right challengeth the middle place.

QVEST. XV. *The arguments of the Philoſophers.*

ALthough thoſe things which are alleadged in the precedent Chapters, ſeeme to proue nothing elſe but the rank or following order of the Senſes, and if any thing doe inferre a concluſion, it is onely probably, yet there be which doe contend for the primacie of the ſight with ſtrong arguments.

Sight is by nature before the other ſenſes.

And firſt, they ſay that Sight is the firſt by Nature, as *Ariſtotle* witneſſeth in the 7. Text of his 2. booke *de Gener. et Corrupt.* Wherefore if wee will obſerue the order of Nature, we muſt begin with the Sight.

And more noble.

Secondly, that which is more noble then the reſt, doth deſerue the firſt place. But Sight not only in reſpect of the Senſe, but of the Organ alſo, yea of the *meane* and obiect doth excell all the other in dignity. To theſe we adde, that ſight is more liable to our vnderſtanding, and therefore we are to treate of it in the firſt place, becauſe many things are found in it more facile and eaſie which alſo may prepare the minde vnto the knowledge of the other Senſes: for the Organ thereof is very conſpicuous; the *meane* is manifeſt, the obiect is cleare and other things which in the reſt of the Senſes bee very obſcure are perſpicuous and knowne in this: neither is it a ſufficient obiection to ſay, that in reſpect of the act of *perceiuing*, this Senſe is moſt hard and difficult to be vnderſtoode.

QVEST.

QVEST. XVI. *The Arguments of the Physitians.*

WE come now vnto the reasons which are brought for the confirmation of this opinion both of *Plato*, of *Galen* and of the Anatomists, and they are taken partly out of *Aristotle* and partly out of the propriety of order. For *Aristotle* in the 37. Text of his 1. Booke of Physicks: teacheth that we must begin with those which bee most common; both because (as *Auerhoes* expounds it) those things which be most common are best knowne, and also because the affections which are to bee declared doe primarily agree vnto them: and lastly, least wee should too often fall into *Tautalogies*, or vaine repetitions. And *Aristotle* himselfe giues an excellent reason of this his owne Position, to wit, because without the knowledge of those things which be more common, the lesse common cannot be knowne.

Why we must begin with those which be most common.

Now who will denie that the Sense of Touching is more common then the rest of the Senses? who knowes not that this Sense is common to all liuing creatures? yea it is so common in all, that without it no Sense can bee performed; in so much that the same *Aristotle* confesseth that euery Sense is a kinde of Touching. Beside, Art being the Ape or imitatour of Nature, we therefore in the tradition of our Arts should follow the order of Nature, in which order we must begin with those which are first (not in intention as the former Sect affirmeth) but in originall and generation: wherefore according to the order of Nature Touch seemeth to be put in the first place. To these wee may adde, that this Sense is more knowne then the rest, for a man hath this sense more exquisite then any of the rest; and it doth of necessity follow, that that Sense which we enioy most exquisitely, thereof we should also haue most certaine knowledge.

Touch is the common sense

Touch according to the order of Nature is the first.

QVEST. XVII. *The Authors owne opinion.*

THough both these Sects haue some shew of difference, yet in my opinion they may be reconciled, so that neither of both may seeme any whit blame worthy, in regard that they contend about a matter which is of no great moment, their strife being not about demonstratiue grounds. But because the Schoole of Physitians hath alleadged the more waighty arguments, I will more willingly cast in my lot with them. Yet may any man draw a reconciliation betweene them from the diuers consideration of the order. Some follow the order of Nature in their writings, which order may be vnderstoode to be double, to wit, either the order of originall, or of intention, that is, either by what order Nature doth worke, or what end she presenteth to her selfe in her worke. According to the former consideration the end is the last, but according to the latter it is the first.

A diuers consideration of order.

Againe, some in their deliuerie of Arts follow that order whereby the Art is more easily taught, as for example, some things that come behinde cannot be vnderstoode vnlesse some other things bee præmised before. Others obserue the order of dignity; so that by this diuersity of order being conferred with that which we haue said before, it may easily be gathered what we ought to conclude of either sect.

QVEST. XVIII. *Whether the Senses doe neede a Medium or Meane.*

IT seemeth to be no hard question to determine whether the Senses need a *Medium* or Meane; because out of *Aristotles* Philosophy wee haue as it were an Oracle, 1000. times repeated that *The Obiect placed vpon the Sense doeth make no Sensation*: especially seeing hitherto it is receiued for such an vniuersall principle and ground, that hee which denyes it deserues not to bee confuted. But weighing this as all other Theormes in the equall ballance of Reason, I am bolde to demaund whether this position deserue the Title of a *Principle*? As for *Aristotle* he acknowledgeth it indeede for a principle, and in many places resolueth vpon it for an infallible and vndoubted axiome without adding any reason thereto: but whether herein he hath well done, and whether it be such a ground and principle or no, it will appeare by the due consideration of the conditions required in a principle.

An axiome questioned.

The first condition therefore of a Principle is (as it appeareth *ex posterioribus Analytic.*) that it may be truely affirmed of euery particular of the same kinde, and in my iudge-

Touching and Tasting without *Medium.*

ment sayeth *Placentinus* this axiome transgresseth this condition, because it agrees not to euery Sense to haue a *Medium*, for that Tasting and Touching are absolued without.

The reason why the other are not.

But some may haply doubt how these two Senses can be persourmed immediatly, and yet a *Medium* be required to the rest. The answere is at hand; because the organs of some Senses are so sensible that they would easily bee offended with the contaction of their obiects. So the Sight will not admit of the Touch of any thing, and a vehement motion whereby the sound is generated would offend the organ of Hearing, if it should come immediatly vnto it.

Againe, a fumid exhalation which falleth in with the Sence of Smelling would hinder Respiration, and except it were transported through a *Medium* or Meane, it would bee offensiue and hurtfull to the Organ.

Some Senses perceiue materially others spiritually, as Sight.

Lastly, some Senses doe *Perceiue* their obiects not Materially but Spiritually. Now the *species* must be drawne from the obiect through a *Medium*. Some also receiue them Materially, and those haue neuer a *Medium*. For a colour cannot really attaine to the organ, because an accident out of his subiect is nothing: whereupon it followeth that not the *Colour* placed aboue the eye doeth offend it, but the *coloured* or subiect of the colour.

Not the colour, but the coloured offends the eye.

But put case that Colour could really without any dammage bee imposed vpon the Eye, yet it would not moue the Sence; because it would condense and thicken the eye: for by this immediate contaction the colour doeth worke vppon the *Daphanum* or that which is translucent.

The Taste and Touch receiue reall qualities.

The Touch therefore and the Taste haue no neede of a *Medium*, because they doe not receiue Intentional or abstracted *species* but reall qualities; for if they should receiue Spirituall formes then they must discerne of them a farre off without the contaction of the obiects; for the *species* are diffused into an ample distance; but the Tast and the Touch are not perfected without contaction.

We see moreouer in these Senses reall affects of the obiects, which could not be vnlesse they should be *perceiued* really: but these thinges shall bee more at large discussed in their proper places.

The Sight doth especially neede a *Medium.*

For a playner dilucidation of the trueth, wee must obserue that all Senses haue not alike neede of a *Medium*; but there is a certaine order and degree of this necessity. For the Sight doeth especially neede a *Medium*, because it is most of all Spirituall, and there is no Sensation at all of a reall colour immediatly placed vpon the eye.

The Hearing lesse.

A *Meane* is also requisite to the Hearing, yet it hath lesse neede thereof then the Sight, for a sound imposed vppon the Hearing maketh a kinde of Sensation, but very imperfect, namely such an one as is offensiue to the organ.

The Smelling yet lesse.

The Smell in like manner hath vse of a *Medium* if the smoaky exhalation be vehement; for so it may hinder the Respiration and hurt the organ: yet an odour may bee *perceiued* without a Meane. VVhereupon when we would *smell* any thing perfectly we hould our noses close to it: so that the *Smell* seemeth to be in the middle betwixt those *Senses* which neede a Meane and those which are performed without it.

Tasting and Touching none.

Taste also though it bee made by contaction yet requireth necessarily an humidity, which may bring the Sapors out of *Power* into *act*. But Touching hath need of nothing saue the contiguity of the tactile body, beeing performed without the helpe of any other Meane. And thus I thinke it is plaine what we may determine of this question.

QVEST. XIX. *What the Medium ought to be and of what kinde.*

After we know which of the Senses doe need a *Medium* it followeth that wee make inquiry to find out what this *Medium* is & how it ought to be affected. And herein we must first obserue that the *Medium* ought alwayes to be present; least when all thinges else requisite for Sense bee fitly disposed, yet for fault of a *Medium* we bee made lesse able to performe this act of Sensation.

Fire is not the *Medium*, but Ayre.

VVherefore the *Medium* by whose interposition wee *Perceiue* is not Fire, for this is not alwayes at hand but Ayre, for this doeth alwayes encompasse vs about, it is alwayes present, in it we leade our liues.

2. Reason why the Ayre is the *Medium*

Secondly, this *medium* should alwayes consist in a middle place betwixt the Organ and the obiect; for hence it hath the name of a *medium*, yet so, that it touch both the Organ and the obiect, for otherwise it could not performe his office. But there is no Element which is continually contiguous with our Organs but the Ayre. Thirdly, it is necessary

ceſſary that this *medium* be voyde of all ſenſible qualities, for otherwiſe it would bring the obiect adulterated or defiled to the Organ and affect the Senſe with a proper quality of his owne: VVherefore no compounded body is fit for this function, becauſe all compounded things are ſenſible of themſelues. The conditiõ of a *Medium.*

If you obiect that there be no Elements exquiſitely pure, and that therefore none of them can be a fit *medium* being themſelues ſenſible. I grant indeede that no Element that is neere vs is perfectly pure, yet that Ayre that is neere vs wherein we liue doth exceed the reſt in puritie, and is cleare from all qualities except Tactile, ſo that it may be accounted for a *medium* to all the reſt of the Senſes except the Touch. agreeth with no element except Ayre.

And is there then one *medium* ſeruing to all the Senſes?

Yea, for this is the concluſion which is inferred from the former premiſes, to wit, becauſe this alone is moſt pure, and is alwayes preſent with vs, this alone is continually in the middeſt betweene the Organ and the obiect, this is alwayes cloſe adioyning and touching both the Organ and the obiect. The Ayre therefore alone ſerueth for a *medium* to the Sight as it is Traculent; to the Hearing as it is ſounding; to the Smell as it is capable of odours.

But it may be obiected, that if the Ayre be the onely *meane* of the Senſes, then would it follow that Fiſhes which liue in the water haue no Senſe.

I anſwer, that for their ſight the water ſerueth for a *medium*, but other Senſes they haue none (ſaith *Placentinus*) ſauing their Taſt and Touch, and theſe two haue neede of a *medium*, yet they haue theſe Senſes alſo but imperfect; but if any man will yet more inſtantly vrge, that they haue the Senſe of hearing, we grant they may heare but moſt imperfectly, and for ſuch imperfect ſenſation the water ſerues in ſteed of a *medium*; but we ſpeak here of perfect Senſation, where as the Senſation of Fiſhes is not ſimply perfect, but only in their owne kind, to wit, ſo farre foorth as they haue need of it.

Laſtly, this condition of the *medium* is required to the perfect performance of Senſe, namely, that it bee not too ſpatious or ample, and alſo that it bee not too narrow or little. But what is the limit or extent of this *medium*, that is, how farre or wide it ought to extend it ſelfe, is impoſſible to be determined, for this limit or extent muſt almoſt infinitely be varyed according to the magnitude, paruity and vehemency, as alſo according to the vigor & ſtrength, or imbecillity and weakeneſſe of the Senſe: For we doe not diſcerne Mountains, Cities and whole Countryes but a farre off, and leſſer things wee do not ſee except they be neere at hand. So we doe not perfectly and without offence to the Organ heare a vehement ſound, except there bee a great diſtance betwixt the Sence and the obiect; nor a low voyce except we be neare vnto it. And the ſame reaſon is of the reſt. The termination of the *medium* is diuers.

QVEST. XX. *What an Obiect is.*

AN obiect or that which is ſenſible, *is a quality which mooueth the Organ, and is iudged of by the ſenſatiue facultie.* And although that which is *ſenſible* bee two fold, proper or common, yet I conceiue this definition to be peculiar to the proper obiect; vnleſſe haply it may agree to ſome of the common, & therfore we will ſeuerally define them both. Proper obiects, therefore as *Ariſtotle* witneſſeth in the 63. text of his ſecond booke *de Anima*, are thoſe *which cannot bee perceiued with any other ſenſe, and about which the ſenſes in diſcerning are not deceiued.* And this definition by it ſelfe agreeth to the thing defined. For in that ſometimes the Senſes erre about their proper obiects, it hapneth not of themſelues but from ſome accident; to wit, from the depraudation of ſuch things as doe concurre to this ſenſation; as for example, when all things appeare yellow to thoſe that are ſick of the Iaundies, this hapneth becauſe the Eye is tainted with the yellow colour of choller; and when aguiſh men do iudge ſweet things to be bitter, it comes alſo from choller wherewith the Tong is affected, and that is from euent & accident, not from the proper condition of the Senſe. VVherfore ſeeing that when ſuch impediments or lets are remooued and the obiect *medium* and Organ are naturally diſpoſed, the ſenſe cannot bee deceiued about his proper obiect, it is by good right thus abſolutely defined. An obiect is twofold. What a proper obiect is. The Senſe is not deceiued about his obiect.

For the number of theſe obiects, they are as many as are the Senſes, for colour is the obiect of Sight, Sound of Hearing, Odours of Smelling, Sapours of Taſting, and Tactile qualities of Touching. How many proper obiects there be.

What a common obiect is

Common obiects are those, *which are perceiued, not of all the Sences as some would haue them, but of more sences then one.* Which *Aristotle* teacheth very well in his booke *de sensu et sensili* where he affirmeth, that they are therefore called common obiects, because they are common though not to all the senses yet at least to the sight and touching, for by these two are all things perceiued, though not after the same manner as their proper obiects, to wit, by sending a species from them, or by attaining really to the Organ; but as it were certaine manners and conditions ioyned with the proper obiects *in order* vnto the motion of the sences: so that they doe not absolutely and primarily moone and affect the sence, but onely together with their proper obiects. And because the second doe not worke without the first, therefore the common obiects are not *perceiued* by the externall sence without the proper. And these common obiects are fiue in number according to *Aristotle*, Motion, Rest, Figure, Magnitude, and Number.

When the common obiects moue the sense.

QVEST. XXI. *Of the Organs of the Sences.*

What an Organ is.

THE Organ or Instrument of the Sence as *Aristotle* witnesseth in the 122. text of his second booke *de Anima*, is that *wherein the power and force of perceiuing is seated.* And this Instrument is the eye in the sight, in the hearing the eares, in the smelling the nosthrils, in the taste the tongue; and for the touch, though all the skin yet especially that of the hand. But yet the vertue or faculty of sensation doth not reside in the whole Organ, but in some certaine similar particle, of which kinde is the Cristaline humor in the eye, the nerue of hearing dilated in the Eare, the mamillary processes in the Smell, the proper flesh or pulpe of the Tongue in the Taste, and in the Touch the true skin; the other parts of the Organs assist this particle, keeping it as it were in tune, or preseruing the harmony thereof from the offence and incursion of outward iniuries; for otherwise this sweete musicke, consent and proportion, would by the ouer-vehement force and change wrought by excessiue obiects be destroyed, which concordance being broken there can be no sensation.

And thus much shall suffice to be spoken of the Sences in generall; we will entreate more at large of the particular Sences in their proper places, where also wee will note some things concerning their Organs which will be worthy your obseruation. And first of the Sight according to the order we before obserued in our Anatomicall History.

QVEST. XXII. *Whether sight be made by Emission or Reception, where the nature of the sight is accurately explaned.*

OVR particular controuersies concerning the Sight shal begin with that notable question cõcerning the nature & maner of vision or sight, which is indeed rather Philosophicall then belonging to the art of Anatomy; notwithstanding because *Galen* hath elegantly ventilated it in his books *de vsu partium* & *de Placitis Hip. et Plat.* it shall not bee altogether impertinent to infert some collections in this place which yet wee must fetch out of the secret mysteties of Philosophy.

Three different opinions concerning the nature of sight

There are three especiall or most notable opinions of the Philosophers concerning the manner of sight. Some thinke it is made onely by emission of something out of the eye: others only by Intromission or Reception of something into the eye: and the third sort contend, that it is made partly by Emission, partly by Reception or Intromission.

The first opinion of emission. The masters of the Optick Arts. *Pythagoras.*

Of the first sect there be diuers Authors but all of them disagreeing among themselues. The maysters of the opticks thinke that certaine beames do issue from the Eyes and reach vnto that which is to be seene: the figure of which beames they conceiue to bee pyramidall, the Cone or point whereof is in the eyes the Basis in the thing to bee seene. *Pythagoras* thought that sight was made by an emission of light out of the eye vnto the obiect; which light is reflected againe vnto the eye, euen as a hand-bal strucken against a wal doth rebound backe from the wall vnto the hand with an equall force.

Empedocles.

Empedocles, *Hippocrates* and *Niceus* thinke that sight is made not by Emission of light onely, but of beames also. *Plato* thinkes that the eye sendeth not any beames foorth of it but onely light, and that it also reacheth not vnto the thing seene, but vnto a certaine or proportionable space of the *Medium*. *Democritus*, *Lucipp.* and the Athenian *Epicurus* conceiued that certaine Images or formes did flow from all things through the Motes which be in the ayer. *Chrysippus* and the whole Schoole of the Stoicks, thought that a certain

Democritus. Chrysippus.

spirit

ſpirit aſcended from the heart vnto the Aple of the Eye, which ſpirit was extended as farre as the obiect. And theſe are the different conceits of the Authours of the firſt opinion whereby it is ſuppoſed that ſome thing is ſent out of the Eye vnto the viſible obiect, which opinion the Platoniſts confirme by theſe reaſons.

The *Platoniſts* Arguments.

Firſt, they ſay that witches doe faſcinate or bewitch onely by beholding one with their Eyes, whence it is that the Poet ſayth:

Neſcio quis teneros oculus mihi faſcinat agnos.
I wot not well what witching eye, My tender Lambs hath done to die.

Secondly, they ſay that a Baſiliske doth infect a man, onely by ſeeing him.

Thirdly, that a menſtruous woman doth infect a looking glaſſe as it were with ſome materiall corruption.

Fourthly, that if a Wolfe behold a man he will become hoarſe.

Fifthly, that *Tiberius Cæſar* is reported to haue aſtoniſhed a ſouldior onely by caſting his Eye vpon him.

Sixthly, that *Antipho* (as *Ariſtotle* reports in the third booke of his Meteors) had his owne image euermore before his eyes.

Seuenthly, if we did not ſee by emiſsion how it comes to paſſe, that when wee would ſee more exactly wee draw the Aple of our Eye into as narrow a roome as wee can, Is it not to this end that the beames and ſpirits going out of our eyes may be more vnited.

Eightly, if no thing were ſent foorth of the Eye, how could the Eye be ſo weary with continuall looking.

Ninthly, if viſion were made by reception and not by emiſsion, wee needed not to conuert our Eye directly to the viſible obiect, for wee ſhould ſee whether wee beheld the thing or no.

Tenthly, we could not ſee the magnitude or figure of many things, for the Eye being ſo little a body cannot receiue ſuch great obiects into it ſelfe.

Eleuently, if it were by reception, then would it follow that the more we dilated, the Aple of our Eye, the better we ſhould ſee, becauſe our reception would be large.

Twelftly, diuers or contrary ſpecies or formes would together and at the ſame time be receiued into the ſame Eye, becauſe at once it doth behold two contrary obiects, as blacke and white.

Laſtly, the leaſt thing ſhould bee as eaſily perceiued as the greateſt, the contrary whereof is manifeſt, for the ſharpe point of a needle held vpward to the skie is not perceiued, becauſe the beames being ſeparated cannot meete in one, by reaſon of the paruity of the obiect. But if wee would ſee it, we muſt of neceſsity withdraw our ſelues to the one ſide.

The opinion of the Peripateticks that ſight is by reception onely Their arguments.

To conclude, the Eyes are of a fiery nature, for they are both pyramidall and continually mooueable and neuer ſtiffe, but it is the property of fire, alwayes to ſend ſome thing from it, as light, beames or heate. Theſe be the principall reaſons of the Platoniſts, and of the maiſters of the Opticks.

Let vs now lend our eares vnto the fautors of the other ſect. The prince of which company and opinion is *Ariſtotle* in his ſecond booke *de anima*, and in his booke *de ſenſu & ſenſili*, and his ſteps haue all the Peripateticks followed as *Alexander*, *Themiſtius*, *Auerrhoes*. And theſe thinke that *Sight* is made onely by reception of ſome thing into the Eye, and not by emiſsion of any thing forth. And that for theſe reaſons.

Firſt of all, becauſe that ſeeing Senſe is a paſsion it ought only to bee made by reception. So Hearing is made onely by the reception of ſounds. The Smell by reception of odours. The taſt of ſapours and the Touch of tactile qualities.

Moreouer, they that haue more moyſt and humide eyes do alwayes conceiue the obiects to be greater then they are, becauſe the ſpecies are repreſented in a greater ſhape, by reaſon of the humiditie.

Thirdly, an ouer vehement obiect doth hurt the Senſe.

Fourthly, we ſee in a looking glaſſe the image of the thing oppoſite vnto it, which we could not doe vnleſſe the image of the thing were carryed from the obiect vnto the *medium* and ſo vnto the glaſſe.

Againe *Ariſtotle* in the third ſection of his Problemes asks the queſtion why the right eye ſhould with more agility performe his function then the left, and yet the Eyes and eares

Eares do both of them see and heare alike. He answers, that those Faculties are performed by doing, these by suffering, and that Both the Senses and their Organs do equally suffer.

Sixthly, Oldmen discern better of such obiects as be a farr off then of those which bee neere and that not because of the light, or the beames or spirits sent forth of their Eyes, for they are very small, impure and darkeish; but because the species or forme comming from a remote obiect is made more slender and spirituall and more apt to be receiued into the Organ.

Seuenthly, The smallest Starres in the cleare Winter may bee discerned and not in Summer, because their species or formes beeing receiued into a crasse and thicke Ayre are there terminated and multiplicated: but in Summer by reason of the raritie and thinnesse of the Ayre they cannot be receiued terminatiuely or definitely (for of necessity we must vse our Schoole terms to expresse these matters of Art) neither yet be sufficiently multiplyed that they should attaine vnto our sight.

Galens opinio. Our opinion that sight is made by reception.

Galen in the seuenth Chapter *de placitis*, and in the tenth, *de vsu partium*, to the end that hee might reconcile the *Platonists* with the *Peripatetickes* determineth that Sight is made partly by Emission partly by Reception. Truely for my owne part I reuerence *Galen* as a Master, and hee stands in no neede of my patronage or approbation hee is sufficient of himselfe, yet as he was often wont to say, *vincat vtilitas*, let profit preuaile; so wee say also, *vincat veritas*, let Truth preuayle. I had rather therefore thinke with *Aristotle* (whom I esteeme and respect as another Nature, but an Eloquent Nature) that vision is only made by Reception of species and that nothing is sent foorth of the Eye vnto the thing seene which may helpe the Sight, that is neither beames, nor light, nor spirit. The truth of this opinion may be strengthned with these reasons.

The 1. reason That the Organ of sight is watry & why.

First, the Organ of Sight is watery; now it is the property of water to receiue: that it is watery may bee thus demonstrated. The Organ of Sight ought to bee Tralucent that there may bee a kinde of Analogie or proportion betweene the obiect, the meane, and Organ, that is, betwixt the Agent and Patient. But of shining and cleare bodyes some are rare and thinne, others more dense or thicke. The rare bodyes doe easily receiue the species or images but they doe not retaine and hold them; so the Ayre is full of species, but they presently vanish away and are not perceiued by reason of the rarity therof nay and I say, that such species cannot be discerned in a glasse except they be retayned by lead or some such like dense and thicke body. That therefore these formes of visible things may be held and retained in the Eye, there is required both a transluceut and thicke body; and of this kind is water, for fire and ayre be cleare indeed but rare. The Organ therefore of Sight is watery, of which nature also are the principall parts of the Eye.

The 2. reason which is *Alexanders*.

I will now produce a very elegant argument of *Alexanders*, which is on this manner. That which is sent forth of the Eye is either corporeall or incorporeall. But it is not incorporeall, because incorporeall things can neither issue foorth of the Eye, nor change their place, nor be in the Eye as in a place. It is not corporeall because then the Eye in one day would vterly be destroyed, neither could it in a moment bee carryed as farre as the skie because that no corporeall substance is mooued in an instant.

To these we adde, that when the winde doth blow it would bee dissipated, and so there would be a Penetration of bodyes which is against Nature. Now if you should thinke that the Ayre would giue place to that corporeall substance going out of the Eye, there could be no Sight at all, because there would bee no continuation of those beames with the Eye but some body would interpose it selfe betwixt them.

The solution of the Platonists reasons.

As for those arguments which the Masters of the Optickes and Platonists oppose against this truth, we will thus in order answer and repell them.

First we deny that fascination or bewitching is done onely by sight: except it be by magicke Art.

For the second and third, we also deny that a Basilisk or menstruous womando by their lookes infect any thing, but it is by reason of a certain corrupt and poysoned vapor which breatheth out of their mouth, eyes, nosthrils and from their whole body, which by continuation and succession doth infect thr Ayre.

Fourthly, that which they obiect concerning VVolues, is more worthy of derision then of confutation.

As for *Tiberius*, he did not astonish his souldiour by any beames proceeding from his Eyes, but by his horrid and fearefull looke and countenance.

Sixthly,

Sixtly, as for *Antiphon* it is well knowne he was a foole, and therefore the fault of the occursation of his image or resemblance alwaies before him was in his braine not in his eies.

Seauenthly, we doe angustate or strayten the apple of our eyes, least by the external light our internall spirits should be disipated.

Eightly, the Eye is wearied with looking, by reason of that force and endeuour which the faculty vseth to administer for the establishment or fixing of the eye.

Ninthly, the Eye must bee conuerted or turned toward the visible obiect, because there can be no vision but by a right line.

Tenthly, the magnitude of a thing is not receiued into the eye, but onely the *species* or forme of it, which because it is a thing immateriall, may be wholly receiued into the eye.

To the eleauenth wee say, that the dilatation of the apple of the Eye doeth exolue or spend the spirits which are of absolute necessity for the reception of *species*.

To the twelfth thus; both white and blacke colours may at one and the same time be receiued into the Eye because they are receiued onely by an intentionall and incorporeall species or forme.

Lastly, the poynt of a needle is therefore not perceiued, because it is not a proportioned obiect to the Organ. By these it is plaine and manifest, euen to the dullest apprehension, that vision is performed not by emission or sending forth any thing from the Eye but onely by reception of the species into it.

But the Nature of this reception is most obscure and folded vp in many secret difficulties; for the enodation whereof, that this secret may appeare euident, foure things are to be discussed of vs. First what it is that is receiued. Secondly, where or into what part of the Eye this reception is made. Thirdly, when it is made. Fourthly, how it is made. Foure things to be obserued in this reception.

As concerning the first question *Democritus* and *Lucippus* thinke that corporeall obiects are receiued. *Epicurus* supposeth onely the beames of the visible obiect are receiued. *Alexander* that the image onely of the thing is receiued, not as it were in a subiect, but like as in a glasse. We agreeing with *Aristotle*, thinke that onely the species or images are receiued, and that the quality of these species is incorporeall, immateriall, indiuiduall, the Phylosophers call it *Intentionall*; which is produced in the *medium* or *meane* and Organ, and so multiplyed by a simple effluence or emanation as light proceedeth from the Sunne and a shadow from a body. This species, I say, is not it selfe seene; but it is that whereby we see, for onely the obiect is seene. What it is that is receiued. That onely the species are receiued.

The Eye therefore may very well bee compared to a looking glasse receiuing into it the Images of such things as are obiected and set before it. For a glasse doth receiue all the species, not sending any thing forth: yet in this doth the Eye differ from a glasse, that there is no vertue of the Soule in a glasse which can referre and transmit the image receiued vnto any other thing as it were vnto a Iudge. The Eye is like a looking glasse.

But some will haply demand here, if the species or image receiued be immateriall how can it affect the sight by seuering or gathering together of the spirits?

I answer, that the Eye is not affected by the species, but by the colour, according as it is more or lesse splendent or enlightned, for all enlightned things do dissipate, by reason that our ayry and splendent spirits do vanish into that light which is like vnto them: So white things, because they haue much light doe dissipate the spirits, but blacke doe gather them because they are contrary to the spirits. So when night comes the heate is recalled from without inward, and as *Galen* teacheth in his Commentary vpon the 15. Aphorisme of the first section, we sleepe longer in winter because the nights are then the longest.

VVherefore lucide and white obiects doe hurt the Sight, yea sometimes they make a man blinde, because the visiue spirits being drawne out, and as it were intised by that which is like vnto them, doe breake foorth of the Eye with so great a violence and force that by such irruption, either the substance of the Cristalline humour or the coate thereof or some thing else in the Eye (which hath many tender parts) is either broken, or at least suffers some alteration.

It will be againe obiected, if the reception of the species be immateriall, why should the Eye be wearyed with continuall seeing? why do not prominent and goggle Eyes see better then other, because they are more apt for reception.

I answer, that the Eye is wearyed, not by the impression of species, but by the force and endeauours which the faculcie vseth to doe his worke, which is especially to firme the eye

Eye or hold it ſtedfaſt and to containe the ſpirits; but thoſe that are goggle eyed haue not ſo good ſight, becauſe their animall ſpirits are diſsipated, which are eſpecially neceſſary vnto the Senſe of Seeing, that being ioyned with externall light they might tranſmitte the ſpecies vnto the interiour ſenſe.

Of the place of this reception.

The ſecond propoſition was concerning the place of this reception, to wit, into what part of the eye the ſpecies be receyued. And heere it will not bee in vaine to examine the different opinions of Phyſitians and Philoſophers. Some thinke that they are receiued into the ſubſtance of the Braine, grownding vpon the doctrine of *Galen*, who teacheth that all ſenſe is from the Brain. *Ariſtotle* ſaith, they are receyued into the *Pupilla* or Apple of the Eye, vnderſtanding by the Apple the Criſtalline humor. *Galen* ſaith ſometime into the Criſtalline, ſometime into the Cobweb-coate, which he ſaith is ſmoother and more polliſhed then any Looking-glaſſe.

Ariſtotle.
Galen.

Auicen ſayes, they are receiued in the meeting of the Opticke Nerues, and hence it is (ſaith he) that the obiect appeareth ſingle, becauſe the viſible formes are vnited in that coition or coniunction of the Optickes. We determine that they are receiued into the Criſtaline, becauſe it is the principall and primary Organ of Sight, placed in the very center of the eye, and differing from all the other parts in ſubſtance, figure and qualities. But if you would reconcile all theſe, then ſay, that the *reception* is made in the Criſtalline, the *refraction* in the coates, the *perfection* in the coition or meeting of the Optickes, the *perception* and iudging in the Braine.

Auicen.

Of the time of reception.

Concerning the time of this reception which was the third queſtion; all do agree in one, that viſion is made together with the perception of the ſpecies; but this perception is made in an inſtant, for the heauen is ſeene all at once, becauſe the light which produceth or bringeth foorth theſe *viſible ſpecies* doth diffuſe it ſelfe, and tranſporting them together through the aire placeth them in the extreme ſuperficies thereof that is next of all to the eye-lid, ſo that when the lid opens preſently the ſpecies is offered to the *pupilla* or Apple, and in a moment of time is ioyned therewith.

Of the maner of reception.

Laſtly, the manner of viſion is thus, It is made by the reception of ſenſible ſpecies not of bodies, which ſpecies although they ſeeme to haue ſome taſt of the condition of their owne matter, notwithſtanding they are not carried materially and as bodies are carried, but like the ſhapes or Images of bodyes, brought from the aſpectible obiect vnto the *pupilla* through the aire as a meane by right lines vnto an acute angle. Hee that deſires to heare more of the manner of viſion, let him reade *Alexander* and *Simon Simonius*, a man both for Phyſicke and Philoſophy very excellent, Commenting vpon *Ariſtotle* his booke *De ſenſu & ſenſili.*

QVEST. XXIII. *Whether any thing within the Eye may be ſeene, and whether it may be ſeene by it owne proper forme or by another, where alſo are explained ſome things concerning the nature of Suffuſion and of viſions or Apparitions.*

Whither anie thing within the eye may be ſeene.

HAuing reſolued that ancient queſtion concerning the manner of Viſion, we will proceed to the reſolution of two other doubts, that ſo there may be nothing wanting that can be deſired to the perfect nature of this ſenſe of ſight. The firſt therefore is whether any thing which is within the Eye may bee ſeene: then whither that which is ſeene, is ſeene by his proper Species or by another.

The 1. reaſon

That nothing within the Eye is viſible may bee thus demonſtrated. *Ariſtotle* in his ſecond Booke *De anima* writeth, *Senſile poſitum ſupra ſenſorium ſenſationem non facere, A Senſible Obiect placed aboue the ſenſorium or organe doeth not perfourme anie Senſation.*

Secondlie, if anie thing ſhould bee ſeene within the Eye, then woulde it follow that the Obiect and the inſtrument receyuing the Obiect ſhould bee the ſame.

Thirdlie, the Philoſopher teacheth, that there be three things requiſite and neceſſarie vnto the Senſe of Sight, the *Obiect*, the *Medium* or *Meane* and the *Inſtrument*.

Laſtly, Viſion is made by the reception of ſuch ſpecies as are produced and multiplyed in the aire; but if any thing within the eye ſhould bee ſeene, the ſight would not bee made by the ſpecies, but by a reall obiect.

To

To these we will adde that it would also follow that the grapy membrane which is diuersly coloured would be seene, but that is not seen: wherefore we conclude that nothing within the eie can be seen.

That something within the eie may be seen.

Now on the contrary, that something within the eye may be seene, is proued by Authority and Experience. First the authority of *Aristotle* in the second Chapter of his booke *de Sensu & Sensili* and in the fourth of his *Meteors* seemeth thus to perswade vs; for (saith he) when the eie is rowled or moued in the dark something may be seen within the eie. This Authority is also backed and confirmed by Experience; for in visions or phantisines which doe vsually goe before Suffusions, there do appeare certaine figures, magnitudes, positions and diuers colours, all which are resident in the eie and not in the ayre; for then they would bee equally perceiued of all men, and when a criticall euacuation of blood by the nose is ready to follow, there are seene afore the eies certain red shadowes which they call *marmaryge*. But that these things may appeare more plaine and euident, it will bee behoofefull to note a few things concerning the Nature of Visions or Imaginations.

Authority. Experience.

Of visions or Images.

2. kinds of visions.

Concerning such visions, some are (according to *Galen* in his 4. booke *de locis affectis*) of idle headed men, by reason of the wandring and vncertaine motion of the images, and so franticke men doe hunt after flies, catch at a flocke or feather, pickle at strawes and are terrified, yea start and fly from vaine and false images. These visions are not diseases of the eye, but they are symptomes of the brayne and of the imagination.

Visions by the falt of the braine.

There are also other Visions and representations which are proper to the eyes and the externall Sensitiue faculty; when false imaginations doe obtrude and offer themselues to the eye. For as *Auicen* writeth, there may appeare some small bodies in the ayre and diuers mingled colours which indeede are nothing. This Vision is tearmed by the Arabians Imagination. But *Galen* defines it to be an external apparition hapning by reason of a darke or cloudy vapor which is betwixt the Christaline and the horny coat. It is a symptome or signe of a depraued sight, because certaine outward coloured things doe appeare which indeede are not, the eye iudging that to bee without which indeede is within it.

Visions proper to the eies

What vision is.

The cause of this Symptome is acknowledged of all to bee that shaddowe or cloudy and darke vapour which doth interpose it selfe betweene the horny coate and the chrystaline humour: I called it darke or shaddowy, that is, imperuious, as the Barbarians say; they meane not bright or transluicent. For if that body which is betweene the horny coat and the chrystaline were transluicent, these visions would not runne before the Sight, but the *species* of visible things that are pure and not mixed, would haue been carried to the chrystaline.

The cause of such apparitions.

The place of this small bodie or vapour is the whole space from the horny membrane vnto the chrystaline: for if this vapour had beene contayned betwixt the Chrystaline and the coition or meeting of the Opticke nerues, it would not haue raised any such representation, in regarde that the whole reception of the *species* is made in the christaline alone. But if peraduenture this vapor be mingled with the glasie humor which doth hinder the ariuall of the internall light, it would either diminish and weaken this action of Seeing, or else vtterly extinguish it.

The place of this vapour.

It is manifest therefore, that in the beginnings of suffusions, and in criticall euacuations of blood by the Nose, in the *peripneumonia* or inflammation of the Lungs, in the *vertigo* or giddinesse, in the loathing of meate or vomiting; there are gnats and flies & certaine red shadows called *marmaryge* before the Eyes; all which are not in the externall Ayre, for then they should be seene of all men, but are contained within the Eye. We will therfore thus determine the propounded question. That some thing within the eye may be seene, because the obiect is present, that is to say, an interposed body, a *medium* transluicide which is the wateriſh humour and the principall Organ of Sight which is the Cristalline humour. Yet we affirme that this vision is not perfect. The reasons which are alledged for the contrary opinion and the authorities of *Aristotle* are to bee vnderstood of perfect vision.

What we hold.

But there is another more obscure question, yet to be resolued, namely, whether that which is within the Eye when it seemeth to bee in the outward Ayre be seene by a proper species of it owne or by a strange species.

Question.

I answer, that it is by a strange species; for the vapour which is contained betwixt the horny membrane and Cristalline, is not *perceiued* in the shape and species of a vapour, but vnder

Solution.

vnder another ſhape conteined in the aire; yet this ſtrange ſpecies, when it is receyued into the eye, it followes the Nature, colour, figure and magnitude of that vapor which is already exiſtent in the eye, ſo if the internall vapor be greeniſh or yellow it repreſents the ſpecies of the externall obiects (as of a wall or booke) yellow and greeniſh. If the vapour be ſmall and diffuſed; there do appeare as it were flying Gnats: if it be ſtretched out in length haires do appeare.

Why that which is within doth apear

Now if that which is in the Eye ſhould be ſeene by a proper ſpecies of it owne, the inner Grapie coate which is diuers coloured would be ſeene. Finally, the laſt knot which remaineth to be vntied is this, why that which is within the eye ſeemeth to bee out of it?

Solition

I anſwere, that the Criſtaline humour being accuſtomed to the viſion of external things doth iudge whatſoeuer is within to be without.

QVEST. XXIIII. *Whether the Organ of Sight be Fiery or Watery.*

Plato ſaith it is fierie.

COncerning the Nature of the Eyes the *Platoniſts* & *Peripatetiks* are at great ſtrife. *Plato in Timæo*, becauſe he is perſwaded that viſion is performed by emiſsion of light from the eyes, doth therefore thinke that the eie is of a fierie Nature. The eies (ſaith he) do participate of that fire which dooth not burn, but by illumination doth cheerfully drawe the day out of the Dungeon of the night. Now Fire according to the Platoniſts is threefold. Firſt, that which doth both ſhine and burne: ſecondly, that which ſhineth but burneth not. Thirdly, that which burneth but doth not ſhine. And this opinion of *Plato Galen* ſeemeth to follow in his 10. Booke *De vſu partium*, and in the ſeuenth *De Placitis Hippo. & Platonis*. For he calleth the eye a bright organ and the Sun-like part of the creature.

The Platoniſts reaſons.

The Reaſons of the Platoniſts be theſe. Firſt, the eyes of ſome creatures do ſhine & glitter in the night, as of Night-Owles and of Cats. Againe, ſome in vehement fittes of anger haue their eyes as it were burning and enflamed. Moreouer, when the eie is ſhot at one ſide, we ſee a kinde of fierie glaunce like Lightning, and the Eye being rubbed in the darke doth yeelde a bright glimpſe vnder the finger. *Ariſtotle* affirmeth, that *Antiphon* had his owne ſhape and Image continually before his eies. And *Pliny* reports many things of *Tiberius Ceſar* in the 11. booke of his Naturall Hiſtorie. *Galen* alſo in the ſeuenth Booke *De Placitis Hippocratis & Platonis* maketh mention how it hapned vnto one many nights before he vtterly loſt his Sight, that he perceiued a great quantity of light to yſſue foorth of his eyes. Furthermore that the eyes be fiery may be thus demonſtrated, becauſe they are verie agile, plyable and mooueable: now facility of motion is from heate. They are alſo tranſlucid of a pyramidall Figure and full of ſpirits, becauſe they performe their functions in a moment. To theſe we adde, that to the moſt noble *ſenſorii* or organ is due the nobleſt element, which is the fire. Againe, the ſenſes are of the ſame Nature with the things which are ſubiected to them: but colours are of a fierie Nature, for ſo *Plato* defines colour to be a flame yſſuing from the bodie coloured.

The opinion of *Ariſtotle* that the eie is watery.

Laſtly, the eyes neuer grow ſtiffe as do other parts of the bodie, whence it followeth that they are of a fierie nature. On the contrarie part, *Ariſtotle* and all the Peripatetiks do contend that the eye is waterie, but he that deſires more ſatisfaction heerein may reade thoſe things which the ſame *Ariſtotle* writ againſt the Platoniſts in his Booke *De Senſu & Senſili*.

The authority of *Hippocrates*. *Democritus*. Reaſons.

We will ſubſcribe rather to this latter opinion, and the ſame doth Diuine *Hippocrates* affirme in his Booke *de locis in homine*, *The Sight is nouriſhed by the humiditie of the Braine*. Of the ſame minde alſo was *Democritus* as *Ariſtotle* reports in his Booke of Senſe. Laſtly, Anatomie and the whole compoſition of the eies doth conuince this. For the principall parte of the eye which firſt of all cauſeth viſion is all ycy, which part being drowned in the glaſſy humor, hath in the forepart a watery humor ſo diſpoſed for a defence. And if the eye be hurt or wounded, whatſoeuer doth flowe from it is watery.

Carpentarius reconciling *Ariſtotle* & *Plato* is reprooued.

Some haue laboured to reconcile *Plato* with *Ariſtotle* after this manner: There be two things to be conſidered in the eyes which concurre to this act of viſion: firſt a moſt clear Viſiue ſpirit flowing from the Braine through the Optick Nerues, and ſecondlie the Criſtalline humor. Now according to this diſtinction they ſay, that in regard of the ſpirits & the internall light, as alſo of the enlightned obiect the eye is fierie, but in regarde of the Criſtalline it is watery. But this diſtinction ſeemeth not to be altogether tollerable, for ſo euery organ ſhould be fiery, becauſe the organes of all Senſes haue their animall ſpirites

of

of the ſame Nature, tenuity and brightneſſe. For there are not diuers kindes of the Animall ſpirits; that ſome ſhould be appointed to the ſight, others to Hearing: I therefore hold it better to affirme ſimply according to *Ariſtotle* and indeed the truth it ſelfe, that the Organ of ſight is watery.

Concerning thoſe reaſons which are produced in defence of the *Platoniſtes*, they be of ſmall moment; for the eyes doe ſhine indeede, and oftentimes a bright ſplendour doth proceed from them, but not by reaſon of the fire, but becauſe of the tralucencie, playnnes and ſmoothnes of the chryſtaline and the coates; for whatſoeuer things are ſmooth and neate do ſhine in the dark, as horne. Againe, it hapneth becauſe the externall light receiued of the chryſtaline doth not preſently vaniſh. They are mouable & for this cauſe called by the Poet *faciles*, yet thisis not from the fire but from an aboundant and ſlippy humidity, from the ſpirits and the fixe ſtrong muſcles, by which it is an eaſie matter for a ſmall member to be moued.

The reaſons of the Platoniſtanſwered

Why the eye doth ſhine.

They are called ſpirituall by reaſon of their action, for they perfourme their function in an inſtant, and becauſe they receiue incorporeall and immateriall *ſpecies* or formes produced & brought thorough the ayre and continually offering themſelues to the *Pupilla* or Apple. They are not ſtiffe, yet this is not becauſe they are firy, but as *Ariſtotle* teacheth in his Problemes, becauſe they are inuironed with aboundance of fat; which fat though it haue for his efficient cauſe a defect or weakeneſſe of heate; yet notwithſtanding by his reflexion it doth augment the heate, and by his ſlimineſſe doth hinder the ingreſſe of the ayre which beateth vpon them. To theſe wee ioyne the plenty of animall ſpirits, and the perpetuall motions of the eyes.

Why they are called ſpirituall.

Why not ſtiffe

QVEST. XXV. *Wherefore the Eyes be diuerſly coloured.*

ARiſtotle in the ſecond book *de Anima* ſaith, διὸ ὄργανον *omne* ἄποιον εἶναι. *Euery Organ muſt be deuoyde of any quality*, leaſt all things ſhould ſauour of that ſame quality which is in the Organ: but the Eyes are the Organs of Sight, they therefore ought not to bee coloured, for if they were, all things would appeare to bee of the ſame colour; for all things appeare red to thoſe that labour of an inflamation of the Eye, or haue the blood collected in them by a blowe, or ſtripe, or otherwiſe.

In like manner, thoſe that are troubled with the Iaundiſe, becauſe their Eyes are coloured with yellow choller, doe ſee all things as if they were yellow. On the other ſide, that the Eyes are coloured, euen our owne Senſe doth teach vs; for ſome men are Wall-eyed, ſome mens eyes blacke, ſome mens skie-coloured and others greeniſh, and ſo in the reſt. We anſwere according to *Ariſtotle*, that the name of Colour is ſometimes vſed more largely, ſometimes more ſtrictly. In this large ſignification all things which may be ſeene are ſayed to be coloured. So tranſlucent things though that cannot limit or determine the ſight yet are they coloured. *Ariſtotle* in his booke of colours cals the ayre white and the fire red. But there is another acception of colours more ſtrict whereby it is defined thus. A colour is the extremity of a terminated pellucide body.

A double acceptation of colours.

In the firſt ſignification the whole eye is coloured, all his partes are coloured, becauſe they are aſpectible and may bee ſeene, but in the latter ſignification onely the coniunctiue and grapy coat are truly coloured, for the *Adnata* is white, the grapy is diuerſly coloured, blacke, blew and graſſe-greene, to recollect the ſpirites that were before diſsipated or diſperſed, that it might breake the ſplendor of the external light, and that the chryſtaline humor might be as it were refreſhed with that colour as with a Looking-glaſſe. But the principall part of Viſion which receiueth the *ſpecies* of viſible thinges and is changed by the colours is not at all coloured but bright and lucide only. Now light and perſpicuity or natures common to all viſible *ſpecies* which helpe the reception of theſe *ſpecies*. *Ariſtotle* hath obſerued in lib. 5. chap. 1. *de generat. Animal.* which alſo *Pliny* repeateth in lib. 2. cap. 37. of his Natural hiſtories, that onely the eyes of a man are of manifold & diuers colours: in other creatures the eies are all alike according to their kind: ſo the eies of all Oxen are blacke, the eyes of Sheepe watery, of other creatures redde, excepting a Horſes which are ſometime wall eyed, but the eye of a man is diuerſly coloured.

How the eie may be ſaid to be coloured.

Of the colours of the eye ſome be extreame ſome of a middle nature. The extreame colours are according to *Ariſtotle*, *Galen*, and *Auiten* two, namely the whitiſh or wall coloure and the black. This wall-colour is ſomewhat whitiſh, and *Ariſtotle* in his 5. book *de gener. Animal.* and *Galen cap. 27. Artis paruæ* ſeeme to oppoſe this wall-colour to blacke.

The differences of the colours of the eye.

This *Cæsius* or wall-coloured the Grecians call γλαυκὸν from a Night-Owle which is called γλαὺξ, whose eyes shine with a greenish whiteneſſe. Some do confound γλαυκὸν & χαροπὸν, and yet they are to be distinguished, for though either colour do somewhat tend to greene, yet this γλαυκὸς or wal-coloured doth approch neerer to white, & χαροπὸς or tawny vnto Red. *Aristotle* in his Phisiognomy of the eyes affirmeth this wall-colour in the eie to be a signe of a fearfull man but this Tawny colour of a bold and stout courage; therefore the Eyes of Lyons and Eagles are properly said to be χαροπὸι or Tawny, but the eyes of old men and children to be wall coloured. Either colour doth shine, but that brightneſſe which is in wall eyes is more white like that which is in the scales of Fishes, in tawny eies the splendor is fierie as it is in burning coales. The intermediate or mixt colours of the eies are diuers, according to the diuers mixture of the extreames.

The cause of the variety of colours.

Concerning the causes of this varietie of colors there are diuers opinions according to the diuersity of men. *Empedocles* composed the eie of Fire and water, wherefore hee supposed that the wall-colour proceeded from the predominance of the fire, & the blacke from the aboundance of water.

Empedocles.

Aristotle in his fift Booke *De generatione animalium* referres the cause of these Colours vnto the plentie or scarsity of humors which he doth illustrate by this example of Aire and water. For (saith he) if we looke into a deepe water or into thick aire, they wil both seeme blacke and obscure; but if either of them be rare and thin the colour will appeare Tawnie and splendent. The blackneſſe therefore of the eye is from the plentie and aboundance of humors, the wall eie is from the paucitie and scarseneſſe.

Aristotle.

Auerrhoes.

Auerrhoes thinkes that the whiteneſſe of the eye proceedes from coldneſſe, because for the most part all white things are cold, as the Braine, the Fat, the Marrow, the Bones, the Membranes; and blackneſſe from heate.

Galens opinió

Galen in the 27 chapter *Artis paruæ* referres the cause of colours vnto the plenty, splendor and situation of the Cristalline and watry humors. For (saith he) a wall eie commeth by reason of the plenty or splendor of the Cristalline, or because of the prominent & bunching situation, and also the paucity and purity of the thin and waterie humor. But a blacke eye comes either from the scarsitie of the Cristalline, or from the ouer-deepe situation of it, or because it is not exquisitely splendid and cleare, or because the waterie humor is too aboundant, and yet not altogether pure. Thus farre *Galen.*

Auicens opinion.

Auicen referres the cause of the variety of these colours vnto the Grapie coate, which as it is diuersly coloured it selfe so it doth produce diuers colours in the eie, a black coat causeth blacke colour, as a blewish coate a colour of the same kinde, and his opinion dooth *Vesalius* follow.

But to the end that we may reconcile the different opinions of so graue Authours wee do acknowledge three causes of this variety, the Humors, the Coats and the Spirits. The Humors of the Eye are three: first the watery, secondly the Cristalline, thirdly the Glassy. This last becaufe it cannot be perceiued and is placed in the hindmost part of the eie doth conferre nothing or verie little vnto the diuersitie of colours: but this vertue of alteration and changing the colour of the eye dependeth most vppon the watery and Glasfy or Cristal humor. In these humors also three things are to be considred, their Substance, Quantity & Situation. By the name of Substance I vnderstand the purity or impurity, the splendor, darkneſſe, teuuity and denſity. The Quantity doth note the plentie or scarsity of the humour. The Site is either more hollow and profound or more prominent and bearing out.

The first cause referred to the humours.

In humors 3 things to bee obserued.

There be therefore three causes in respect of the Cristalline, of a wally and white colour in the eie. First, the plenty of the Cristalline, secondly the purity and splendor thereof and his prominent Situation, for so the Cristalline humor by his own & proper brightneſſe illuminateth the watery humor and the whole eie. By reason of the waterie humour there bee two causes of this wallineſſe, the splendor and the paucity or scarsity of it, for a small and pure watery humor doth leſſe hinder the fulgor or brightneſſe of the cristalline Humour.

The causes of blackneſſe are quite contrary, as in the behalfe of the Cristaline the paucitie or smalneſſe of it, his impurity and deep situation; and in respect of the watery the impurity and plenty is the cause thereof. But haply that which *Aristotle* writeth in the 14 Probleme and the 14. Section may seeme to contradict our assertion, where hee saith the Ethyopians haue blacke eies, and those that inhabit the North white, but in the Ethyopi-

The cause of blackneſſe.

Obiection.

an

ans there is leſſe plenty of the watery humour, by reaſon of that ambient Ayre exicating or drying vp all things, in thoſe of the North it is more aboundant.

I anſwer, that the Eyes of the Ethiopians be blacke, by reaſon of the paucity of their Viſiue ſpirits (for they are reſolued and diſſipated by the heate) whereby it happens that the light of the ſpirits failing, the Eye appeares as it were darke or ouerſhadowed. But the Northerne people doe abound with many ſpirits. The intermediate colours doe depend vpon intermediate cauſes. Solution.

The ſecond cauſe of the diuerſitie of colours in the Eye may be referred to the Coate called *ἀμφιβληστροειδὴς*, that is, *vuleam* or the *Grapy coate*, for this onely becauſe it is diuerſly coloured, cauſeth a variegated or diuers coloured Eye. So in the circle of the Eye which they call the *Iris* or Rainebow, diuers colours doe appeare becauſe in that part the *Grapy* coate is diuers coloured. The ſecond cauſe of the diuerſity of colours.

Laſtly, we thinke that the Viſiue ſpirits doe alſo conferre ſomething to the varietie of theſe colours, for thin, pure, cleare and copious ſpirits cauſe whiteneſſe, but craſſe, impure, foggy, and few are the cauſe of blackenes. Now that there be ſpirits in the Eye may be manifeſt by theſe arguments. Firſt, becauſe while the creature is a liue, the Eye ſeems to be exceedingly ſtretched, neither is any part thereof looſe and corrugated, and the one of the being ſhut the *pupilla* or Aple of the other is preſently dilated, to wit, becauſe the ſpirits paſſe more plentifully through the Netlike-coat into the Grapy. Laſtly, becauſe ſometimes the Eyes appeare languide and obſcure, ſometime chearefull and ſplendide or bright. The 3. cauſe.

QVEST. XXVI. *Of the Muſcles of the Eyes and their motion.*

SEeing the Eyes be as ſcoutwatches, night and day watching for our good it is of neceſſity that they ought readily to bee mooued euery way, that with facility they might be conuerted whither ſoeuer we would; and to this motion a Nerue of the ſecond coniugation and ſix Muſcles do ſerue. The firſt whereof lifts vp, the ſecond doth depreſſe, the 3. doeth draw forward, the fourth draweth backeward, and two doe leade the Eye about. By all theſe performing their functions together and ſtretching their Fibers, is the Eye ſtayed and fixed. For it is not (as *Galen* would haue it, and almoſt all Anatomiſts following his ſteps) eſtabliſhed or fixed by a ſeuenth Muſcle compaſſing the Opticke Nerue, becauſe this Muſcle is onely found in foure-footed beaſts which looke prone toward the earth leſt their Eyes ſhould fall out of their Orbes: which Muſcle in a man is neuer to be found. This motion whereby the Eye is thus firmed, the Phyſitians call it *Tonicum* or a ſet Motion, and it is twofold, the one *κατὰ φύσιν* or *according to Nature* when the Fibres of all the Muſcles are equally intended or ſtretched, ſo that the Muſcles ſeeme then to be at reſt; the other *παρὰ φύσιν beſide Nature* when the Eyes remain fixt & immouable whether we wil or no. Which poſition *Hippocrates* in his booke *de victus ratione in morbis acutis* cals *πῆξιν, ἀκινησίαν* and *στάσιν* that is, a Congelation an Immobility or Setting and fixing of the Eye. This fixednes or immobility hapneth when the facultie of the Muſcles which moue the Eye is reſolued, weakned or wholly extinguiſhed, or becauſe theſe muſcles are al equally gathered or contracted into their heads. This poſture of the Eye they call *στάσιν ἰσόῤῥοπον*, that is, a ballanced or equall fixing of the Eye, which affect or diſeaſe is contrary to that they call *ἵππος*, where in the eyes haue a wandring & vnconſtant ſtaring, as a horſe looks that is full fed; whence alſo the diſeaſe tooke his name.

There are therfore only ſixe Muſcles of the eie not ſeuen, and of theſe, foure haue the gouernmēt of the right motions, two do obliquely lead the eye about. And thus may certain differing places in *Galen* be reconciled, for in his tenth booke *de vſu partium*, hee ſaith, that there are onely foure motions of the Eyes; but in the fourth *de locis affectis*, he determines that there be ſixe.

Concerning the originall of theſe Muſcles, Anatomiſts are not al of one minde. Some of them ſuppoſe that they ſpring from the hard *meninx* within the ſcull, but wee are of opinion that the foure right Muſcles together with that oblique whoſe Tendons is compaſſed about with the pully, doe ariſe from that inſide of the Orbe which is made by a portiō of the wedge bone; & this we are taught, ſaith my Author, both by experience & by Autopſie or ocular inſpection. But from the membrane they neither ought nor can haue their originall. They ought not becauſe a membrane of an exquiſite ſenſe doth

compasse the Optick nerue; and therefore the muscles in their motions would compresse this nerue, and so offer violence to the Sight; they could not, because they should not haue adhæred to a firme *basis* or foundation.

QVEST. XXVII. *Two obscure and intricate questions concerning the motion of the Eyes are resolued.*

First question

WE will now proceede to discusse a very hard probleme concerning the motion of the Eyes, the enodation of which knots (for ought I know) hath not as yet beene performed of any man. And it is this: wherefore the eyes considering they haue seuerall distinct muscles by themselues, are yet not moued with diuers motions, but are guided together and at the same time with one and the same motion. Neither can it be that the right eye should be moued and the left stand still; neither can the right be lift vp and the left depressed, which identitie of motion is not to bee found in any other part of the body. For I haue free liberty at the same moment to mooue my right hand vpward and my left downward.

Why the Eies are moued together with the same motion.

The Solution of *Aristotle*.

Aristotle propounds this question in his Problemes, which thus hee endeauoureth to resolue. Though, saith he, the eyes be double, yet there is but one beginning of their motion and the same originall, to wit, in the Coition or meeting of the Optick nerues. Hee therefore referres the cause vnto that Coition.

Auicen the Prince of the Arabians seemeth to bee of the same minde and *Galen* in his bookes of the vse of parts, where he thinketh the Opticks doe therefore meete in one, that one Obiect should not appeare double. These things haue some shew of probability, but they doe not giue vs full satisfaction: For the meeting of the Opticks doth conferre nothing to the motion of the eyes: the Opticke nerue doth onely see and carie the visiue spirits vnto the Christialine, neither is it inserted into the muscles of the eye.

Arist. answere disallowed our reasons.

It is onely the second coniugation which mooues the eies; in that oppilation or stopping of the opticke nerue and in the disease which the Arabians call *Gutta serena* the action of Sight doeth wholly perish and yet the motion of the eies is not a whit hindred; the meeting therefore of the optick nerues doth nothing further the motion of the eyes. Some haue obserued that in many men who all their life long neuer complayned of their Sight, the Opticke nerues were so framed, that they were continually seperated and did neuer meete together. It is therefore very fond and absurd to thinke that both the eyes are moued with the same motion, because there is one onely beginning of motion in the meeting of the Opticks; seeing neither that Coition nor yet the Opticks themselues doe any whit further the motion, but onely the Sense of the Eyes.

The true resolution of the question.

We doe acknowledge a double cause of this motion, the Finall and Instrumentall. The Finall cause is the perfection of the Sense. And this is the perfection of the Sense, that the Obiect appeare euen such as it is; but if the Eyes were moued with diuers motions, that one might be caried downeward the other vpward, surely euery Obiect though in it owne nature one and the same, yet would continually appeare double; and so the most noble Sense would be deceiued and the action of Sight would bee imperfect. If this seeme harsh to be beleeued you may thus make triall of it. If you either lift vp the one eye, or depresse it with your finger you shall see all Obiects double, and discerne the one to be higher and the other lower, because the one eye is moued vpward the other downward. But if you shut either of them, this double apparition of the Obiect will vanish, although you presse that eye with your finger: Also if you mooue your eye to the right hand or to the left, the Obiect will not appeare double, because the Aples of the eyes remaine both in one line.

Question.

Solution.

But wherefore vpon the diuers motion of the eyes the Obiects are doubled, is a thing worthy to be vnderstoode. *Galen* in the thirteenth Chapter of his 10. booke *de vsu partium* writeth, that the Diameters of visible Cones or turbinated formes must be placed in one and the same plaine; least that which is but one should appeare double. But if one of the eyes be moued downward, the Aples of them both will not be in the same plaine and the same superficies; and so the Obiect would appeare double. For then because the beame of the one eye doth not equally reach the Obiect, as neither doth the beame of the other, that which the Sense *perceiueth* twise, it perceiueth as if it were double or two seuerall things; which also happeneth in the Sense of Touching, for if one finger be so folded with the other, that it be layed aboue it, and therewith a man touch a stone, the

Touch

Touch will iudge that to bee double which is but one. In the Palsie or the conuulsion of the muscles of the eye, it hapneth that the Obiects present themselues in a double forme, because the eyes depart from the same superficies: so also the Opticks being either loosened or conuelled, the pupilla or Aple doth not reteine his equality, whence it commeth to passe that all things appeare double, and so sometimes a drunken man will thinke all thinges that he seeth double. In like manner, some that are *Strabones*, that is Squint-eyed, doe see things double, because one of the Pupillaes is either raised vp or depressed. But if the eyes be in the same plaine, though they be two, yet the visible thing is presented simple before them, because the same Species and the same magnitude at the same time is receiued of both the eyes, and are together offered to the Common Sense, which doth not discerne any thing but that which is present.

We conclude therefore, that first in respect of the finall cause, (which as wee haue often repeated out of *Aristotle*, is the first and chiefe cause in the works of Nature) it is that the two eyes bee together and at once mooued. I say, this is because it doth much tend to the perfection of the Sense. And Nature doth continually fit her Instruments as they may best further the finall cause, which whither you call the vse or the necessity it is no great matter. And therefore she hath so disposed the nerues of the second coniugation which doe carie the comm aund of motion and the animall spirit into the muscles, which are therefore termed *Porters* and *Cadgers*, that in their beginning they are continuall, making as it were on chord, whence it is that the right cannot be moued but the other will follow his motion. And this is a new a id a most elegant obseruation. The conclusion.

The other question we shall discouer out of *Cassius*, to wit, wherefore the disease of one eye doth more vexe vs then if both were diseased? Whether it is because when the one eye is sound and according to Nature and therefore is diuersly moued, the sore eye is also mooued therewith? Hence it is that the mutuall and equall motion doth exasperate the payned eye. For when a member is affected it would haue rest. But if both the eyes be effected together, the paine becomes more tollerable, for they both rest together, and from that rest they sooner attaine vnto their former naturall disposition. The second question why the disease of the one eye onely doth more prouoke vs. Solution.

QVEST. XXVIII. *Of the Humours of the Eyes, whether they be animated parts.*

THe Humours of the Eye are three, the Cristalline, the VVaterie, and the Glasie. Of these the Cristalline is the principall Organ of Sight, as *Galen* teacheth in the 2. booke of his Methode, in his 8. booke *de Instrum. Odoratus*, ithe 8. and 10. *de vsu partium*, and the first *de Symptom. causis*. And these arguments amongst the rest doe euince it. That this Humour is the most cleare and shining of all the rest; that it is seated in the middle of the Eye; that it alone receiueth the Species and Images of things; that it onely is altered by colours; and that in it is made the concourse and meeting both of the Externall & Internall light. And therefore when the beating of both the lights vpon the Cristalline is hindered by suffusions and obstruction of the Opticks, the Action of Seeing doth quite perish as if a Candle should be extinguished or put out. The Cristalline is the principall Organ of Sight.

Now concerning this Cristalline humour, there may three questions be demaunded. First, whether it be a part. Secondly, whether it bee a Similar or Organicall part. Lastly, whether it perfourme the Action of Seeing by his temperature or by his conformation.

That it is an animated and liuing part of the body may be confirmed by authority and also by reasons. For authority we haue *Galen* in the 6. Chapter of the first booke of his Methode, and also in the first booke *de Sympt. causis*, accounting the Christalline among the parts. Reason also perswadeth vs no lesse: for it doth primarily & principally performe the Action of Seeing; and Actions are not but of parts only. Againe, it is nourished and liueth and is generated in the wombe together with the other partes. It hath moreouer his proper circumscription: and lastly, it is a body adhæring to the whole, and ioyned in the Societie of a common life, framed also and made for the vse & office of the whole. That the Cristalline is a part. Authority.

But whether it bee a Similar or Organicall part, it is greatly controuerted. Some doe contend that it is not a Similart part, because, say they, it is neither bone, nor gristle, nor ligament, nor membrane, nor yet any of those tenne which *Galen* describeth in his booke *de Inaquali intemp. de Elementis & de Temp.* Whether it be a Similar part.

Contrariwise it is prooued to bee a Similar part in the sixth chapter of the 1. booke of his Methode, for those, sayth he, are called Similar parts which may be cut and diuided into parts like themselues, as the Cristalline and the glassy humours in the eye. And in another place he sayth. That in euery perfect Organ that is a Similar part which is the beginning and cause of the action; as in the eye is the crystalline; and that it is an Organicall part the situation thereof in the middle of the other humour, his figure like a Lentile or Fitch, and the magnitude of it doe demonstrate which three are of the essence of an Organ.

I answer, that a Similar & Organicall part are not opposed one to another. It is no matter therefore whether you call this Cristalline a Similar or an Organicall part. For it is Similar, both by reason of his substance and temperament, because it is wholly watry, pellucide or bright and like it selfe in all parts. It is also Organicall by reason of the figure, whereupon *Galen* in first booke *de Symptomatum causis*, determines that some of the affects of the Cristalline be Similar, as his dry distemper which maketh the disease called *Glaucoma*, & the moyst which makes that affect which they call ῥυπλαλοπίαν: other affects are Organicall, as when it is mooued from the naturall situation, vpward downeward, to the sides, inward & outward; add hereto the greatnesse, littlenesse, and the solution of continuitie. And whereas *Galen* doth make mention only of ten Similar parts he meaneth onely Common parts, which are found almost through the whole body: for the marrow of the braine and of the backe, and the humours of the Eye are parts, and yet may not bee referred to any of those Ten.

Whether the Cristalline performe his functiō by his conformation or by his proper temper.

But it is a poynt of deeper contemplation and requires more diligent inquisition to know whether the Cristalline performe this act of sensation as it is a Similar part, or as it is Organicall, that is, whether by vertue of his temper or by the meanes of his figure; yet *Galen* in the sixth chapter of his first booke of Method seemeth to referre it to the temper; for, saith he, the Cristalline is the principall Organ of Sight, because it is altered by colours, and this alteration is from the purity and brightnes of it; now the purity and brightnesse come from the temperament. Indeede the magnitude, vnity, lentil-like figure of it, and his situation in the middest of the humours are not without vse, but they afford the same helpe vnto vision that the other humours and the Membranes doe, that is, they make it more perfect: It is therefore manifest enough by this that hath beene sayde, that the Cristalline humour is a part.

Whether the glassy humor be a part.

But the question is more ambiguous concerning the glassie and watery humours. All the Antients thought that the glassie was the nourishment of the Cristalline, and the watery the excrement of it. *Galen* in the 10. book *de vsu partium*, writeth that the glasy humour turneth into the Aliment of the Cristalline; for saith hee, it could not bee that the Cristalline humour which is white, cleare and splendent should be nourished by pure & meere blood, because it doth much differ there from in qualities; it therefore required an Aliment more familiar and nearer to it owne nature, and this proximity and familiarity is in the glasy humour which is composed by Nature fit to make the Aliment of the Cristalline. For this glasy humour by how much it is thicker then blood and more white, by so much doth the Cristalline exceede it in humidity and whiteneſse. But if the Cristalline be nourished with the glasy humour, then cannot the glasy be an animated part, because no part doth nourish another.

That it is a true part.

Yet *Galen* in the sixth chapter of the first booke of his Methode, nameth the glassie humour in the Catalogue of the Similar part, and in the first chapter of his tenth booke *de vsu partium*, he thinkes that it is nourished by διαπίδησιν or Transumption by the coate which compasseth it about. If then it be nourished it is a part.

We suppose the glasy humour to bee no lesse an animated part of the eye then the Cristalline, for it hath a proper circumscription, it is generated in the wombe of the purest part of the seed, it is augmented as the other parts of the body, it is nourished with blood, it receiueth veyns from the *hairie crowne*, it is couered with a proper coate, and being once effused or spent it will neuer be recouered.

How the glassie humour doth nourish the cristalline.

They which say that the Cristalline is nourished with the glasy humour doe speake improperly: indeede it prepareth the blood for the Cristalline by changing it, least the pure Cristalline should be infected with a red colour and with veynes; for it behooued that the Cristalline should be deuoyde of all colours; yet the substance of the glasy humour doth not transforme it selfe into the cristalline, nor is assimilated into it. And (saith *Galen* in his booke of the eyes) the glasy humour is affected to the cristalline as the stomach is vnto the

the Liuer;but the Stomacke doeth prepare and miniſter meate to the Liuer as a Cooke, and ſo doth the glaſsy humour to the chryſtaline.

Auicen thinks that the vvatery humour is an excrement of the chryſtalline, and therefore denies it to bee a part. Adde moreouer,that it is fluide like bloud and hath no proper circumſcription. But vvee call it a part becauſe it continually keepeth the ſame proprieties of figure,purity and quantity; becauſe it performeth ſome vſe vnto the chryſtalline, and is as it were a defence vnto it, and like a ſpectacle to carry the images vnto the chryſtaline: wherefore *Ariſtotle* cals it the *Porter* or *Cadger of Images*. This humour alſo if it ſhould flow out cannot be recouered,& ſuch effluxion doth wholy extinguſh the ſight. But all theſe properties doe not agree with an excrement. Moreouer it is heereby demonſtrated that it is not an excrement of the chryſtaline, becauſe the coate called *Arachnoides* or the Cobweb doth intercede or come betweene theſe two humours.

Auicens opinion.

Auicen refuted.

If they obiect and ſay that it flowes vp and downe like blood and doth not adhere to the whole. I anſvvere that it flovveth vvhen it is out of the eye,but not at all vvithin the eye,neither doth it change his place but is continually contayned in a certayne and proper ſeate.

QVEST. XXIX. *Of the originall of the Opticks,their meeting and inſertion.*

SOme thinke that this Opticke nerue is not a whit inferiour to the Chryſtalline humour in dignity,vſe and neceſsity. For *Auicen* is of opinion that the *ſpecies* and images of viſible thinges are hereinto receiued. Wee haue already taught (with *Galen*) that the chryſtaline humour is the principall organ of Sight, and that the Opticke nerue is the conuayer of the viſiue faculty and the internall light, to wit, of the viſiue ſpirit.

But that the hiſtory of the Opticks may be made more manifeſt,there are foure things to be inquired into.

First,what is their originall. Secondly,what is their inſertion. Thirdly,how they meete or are conioyned. And fourthly,whether they be hollow.

Concerning their originall and beginning there bee diuers opinions. *Auicen* thinkes they ariſe out of the forwarde ventricles of the braine; others out of the Center of the brayne,and ſome out of the After braine. We haue obſerued,ſayth *Laurentius*,that out of the lower and hinder part of the brayn neare vnto the ſpinall marrow,yea out of a part of the ſpinall marrow it ſelfe within the Scull two of the moſt large and ſoft nerues of all the braine doe ariſe.

Diuers opinions of the originall of the opticks.

They could not ariſe from the forward ventricles of the braine, becauſe there weere the Mammillary proceſſes, nor from the middle Baſis of the brayne, becauſe this place was appoynted for the purging thereof; nor yet from the After-braine becauſe the Sight requireth a very ſoft nerue, but the After-braine is very hard and not white. The Optickes therefore muſt ariſe from the lower and hinder part of the brayne; out of each ſide one,which being obliquely ſtreatched out and ſeparated,do meete in one almoſt in the middeſt of their progreſſe.

The true opinion.

Concerning this their meeting two queſtions are to be reſolued,to witte, howe they meet,and ſecondly why they meet.

Of the meeting of the opticks.

The manner of their meeting hath not beene knowne till of late dayes. For almoſt all the ancient Phyſitians hold,that in their contaction they thwart one another like a croſſe, (which thwarting or interſection is called χιασμὸς) and ſo the right nerue is carried to the left eye,and the left to the right eye. Others doe not thinke that they thus croſſe and interſect one another but onely obliquely touch themſelues.

But we,ſaith *Laurentius*, ſomething more accuratly and diligently contemplating the manner of this coition or meeting of the Opticks,do thinke that the marrow is mingled and confuſed in the middle of either nerue. For if they were only contiguous touching one another and not mixed and confuſed,the *Pupilla* or Apple of the one eye woulde not ſo in a moment be dilated when the other is ſhut. The Opticks therefore doe meet and are ſo mixed in the middle of their paſſage or iourney,that the one cannot by any Art be ſeuered from the other: this is the manner of the coition of the Opticke nerues.

The manner of their coition.

Now it behoueth that we looke vnto the finall cauſe,namely, wherefore the Opticks doe meete. First it was neceſſary that they ſhould meete for ſtrength, to wit,that by this con-

coniunction or embracing one of another they might not ſuffer any violẽce in the whole length or tract of their iourney. For being of all the nerues the moſt ſoft, and creeping ſo long a iourney they would haue been looſe and flaccid, nor carried in a right line into the *Pupilla* or Apple, vnleſſe they had beene vnited in the middle of their paſſage.

So Nature is wont to ſtrengthen thoſe things which are more ſoft and weake as it were vvith knottes in the middeſt, as may appeare in the right muſcles of the *Abdomen* or Paunch.

2. Reaſon. Secondly, it behoued that they ſhould meete that they might keepe the ſame plaine and *ſuperficies* in the Apple: for vnleſſe they had thus met they vvould haue departed from one and the ſame plaine. So the eyes being deceiued would haue iudged a ſimple obiect to be double: for it behooued (as we haue declared euen now out of *Galen* in the 13 chapter of his tenth booke *de vſu partium*) that the Axes of the Viſiue Cones ſhould be placed in one and the ſame plaine, leaſt the obiect which is ſimple and ſingle ſhoulde appeare double.

The third. *Galen* in the 14. chapter of his tenth book *de vſu part.* acknowledgeth a third cauſe of this their meeting, (to wit) that the formes & Images of viſible things may be vnited. For though the ſpecies be carried through two organs, yet they appeare ſingle and not double. And this was *Ariſtotles* minde in the firſt booke of his Problemes and the third Section, where he demandeth why the eyes are together and at once mooued? becauſe (ſaith he) they haue one beginning of motion (to wit) the meeting of the Opticke Nerues. And *Auicen* is of the ſame opinion.

But I (ſayth *Laurentius*) doe not altogether approoue of this cauſe of theyr coition. For *Veſalius* writeth, that he obſerued in a young man that theſe Opticke Nerues did no where meete, and yet he neuer in the whole courſe of his life complained of any depraua-tion or infirmity of Sight. *Ariſtotle* writeth in his ſecond Booke *De anima* and in the 4. of his Metaphyſicks, that the Senſe is neuer deceyued about his proper obiects. What need is there then of this coniunction? Againe, if wee obtained this by the coition of theſe Nerues, that the ſpecies and formes of either eie be vnited into one, then why ſhould not thoſe many things which are ſeene together appeare but one?

In like manner, though there be two eares and two noſethrils, yet the obiect doth not appeare manifold to the ſenſe. It is not therefore from this coition of the Opticks that the obiect appeareth ſimple, but becauſe the Apples of the eyes are in the ſame plain, and are turned toward the viſible obiect at the ſame moment. Fourthly, ſome would haue the

The 4. reaſon Opticks to meete, to the end they might more fitly proceed out of the perforation in the Scull, and ſo might be carried directly to the eies.

The 5. reaſon Laſtly, *Galen* in the 14. chapter of his tenth booke *de vſu partium* conceiueth that they meete, that ſo the viſiue ſpirit might paſſe from the one eye into the other in a moment for the perfection of the Sight, ſo the one eye being ſhut wee doe ſee more accuratelie with the other. And theſe are all the cauſes of this coition or meeting of the Optick Nerues.

The inſertion of the optick Nerues. Let vs now follow on and declare the manner of their inſertion. The Opticke Nerue dooth conſiſt of a double ſubſtance, an internall which is Marrowye, and an externall which is membranous. The inner Marrow when it attaineth to the Criſtalline humour is dilated and ſo diffuſeth Viſiue ſpirits through the whole eye. Out of this dilatation ariſeth a coate which they cal ἀμφιβληστροειδῆ or the Net-like coate, which (as *Galen* teacheth in the ſecond chapter of his tenth Booke *de vſu partium*) doth neither in colour nor ſubſtaunce deſerue the name of a Coate, but if you caſt it into water you ſhal ſee it reſemble the ſoft, white and marrowy ſubſtance of the Braine.

But the outward part of the Opticke Nerue doth conſiſt of two coates, the one whereof is propagated from the thin *Meninx* the other from the hard, the one is ſpent into the grapie coate the other into the horny membrane; whence it is, that by the continuitie of this Opticke nerue the Animall ſpirit is carried euen in a moment vnto the Apple of the eye.

Of the cauitie of the optick Nerue. Concerning the laſt queſtion which is of the inner cauity of the Opticke nerue, *Galen* writeth in the tenth Booke *de vſu partium* that they are manifeſtly hollow, and therefore *Herophilus* called theſe nerues πόρους, becauſe they are perforated or holed through. But we do not admit this ſenſible cauity in Nerues, yet we would haue them to be the moſt ſoſte of all the Nerues, and more ſpongie that they might receiue and tranſport a more copi-ous and abundant ſourſe of Animall ſpirits.

QVEST.

QVEST. XXX. *Whether the light be the obiect of the Sight.*

THere be ſome which do determine that light is the obiect of Sight, grounding their opinion vpon this foundation, becauſe euerie thing which is ſeen either is light, or it is ſeene by the light, or as *Simplicius* ſaith, that vvhich is ſeene *is either light or nere a kin vnto it*, concluding hence, that light is viſible by it ſelfe, but colours and other things onely by the meanes of light, inſomuch as light is the cauſe wherefore they are ſeene. But none of theſe are true, & firſt of all that propoſition may not be granted, to wit, that whatſoeuer is ſeene is either light or is ſeene by the light, or is very like to it. For if they take Seeing in ſo large a ſenſe *as to perceiue a thing with the Eye* (as it is neceſſary that they muſt grant, for elſe we will denie that the light it ſelfe may be ſeene) then would alſo darkneſſe it ſelfe be ſeene, which neyther is nor may be ſeene by the light, neyther is it of a nature like vnto it. Their reaſons which ſay light is the Obiect of Sight.

Again, all things are not ſeene by light, for there are ſomethings which are made conſpicuous onely by darkneſſe, but in too cleere and ſplendide a light they flye from the Senſe, as the Scales and eyes of Fiſhes, olde rotten wood, yea I ſay the Stars themſelues, which therefore the vulgar imagine do fall becauſe they be obſcured by the light of the Sunne and ſo taken from our ſight, but at the returne of the Euening twylight, (to wit) vvhen the light goeth avvay and the night approcheth they are by degrees reſtored to our ſight again, as in the morning tvvylight they after the ſame manner doe vvithdravv themſelues by little and little from vs. Therfore euery thing vvhich is ſeen is not light or ſeen by the light. Some things are ſeene in the darke. How the Starres are ſeene.

Reaſon and *Ariſtotles* doctrine doe contradict this opinion: for vvee are taught by both theſe that the Eye ſhould be free from his owne obiect, that ſo it may receiue it more ſincerely, but the Eye both in regard of his whole frame and compoſition and eſpecially in reſpect of the criſtalline humour, where the reception of the obiect is properly made is eſpecially light and cleare, light therefore cannot be the obiect of the Sight. Light is not the obiect of the Sight, becauſe it is in the eie.

Moreouer, *to ſee*, is not onely to know a thing with the Eyes (for this is too large a ſignification, and agreeth to many things beſide the proper obiect) but wee doe properly ſee that in which (when it is perceiued with the Eye) the ſight is determined and ſtayeth it ſelfe. But the ſight is not terminated in the light, though the Eyes doe *perceiue* it but reacheth alwayes beyond it. Seeing therefore the light cannot be truely ſeene, it canot bee the true obiect of Sight.

Furthermore, an incorporeall obiect cannot alter a corporeall Organ, except it proceede from a body, that is, be a quality thereof, and then that alteration is attributed to the body by the meanes of the quality; but that viſion be made it is neceſſary that the Organ be altered by the obiect; the light therfore becauſe it is a bare quality (though they deny this) is not to be thought the obiect of Sight, but ſome other corporeall body wherein there is a viſible quality. The alteration of the Organ is requiſite to viſion.

Laſtly, the Organ ought to bee potentially that which the Obiect is actually, but the light is actually incorporeall, and no corporeall body is potentially incoporeall, vnleſſe by the means of ſome actiue qualities, but no ſuch actiue powes proceedeth from the light but illuminatiue and enlightning, whichthey think hath the Nature of an Obiect. But they ſtil obiect that al viſible things muſt be reduced vnto ſom primary *genus*, which may be called an obiect. Seeing therefore light is the firſt of all, becauſe by the helpe thereof others things are ſeen, but light needeth no other helpe, therefore worthily all other viſible things ought to bee referred vnto light as vnto their primary and chiefe *genus*, and ſo it remaineth that light is the firſt and proper obiect of Sight. The Organ ought to be potentially the Obiect.

But beſides that it is denyed that all viſible things are ſeene by the helpe of Sight, as we ſayd before, yet though we ſhould grant ſo much it would not follow that all obiects are to be referred vnto the light as to their firſt and chiefe *Genus*. For viſible things are not therefore ſeene, becauſe they are illuſtrated and made bright by the light, but becauſe they haue another affection which can alter the Viſiue faculty. Wee grant therefore that light doth neceſſarily concurre vnto viſion, but we deny that it is the immediate cauſe therof. Moreouer, it is true that thoſe things which mooue the viſiue Faculty ought to be reduced to ſome one principall *genus* which is called an Obiect. Yet all viſible things both proper and inproper with all which do any wayes fall vnder the Sight cannot be referred vnto any one *genus* and therefore not vnto light. Whether all Obiect be reſtrained to the light as to the generall. After what manner viſible things be ſeene.

QVEST

QVEST. XXXI. *Of the Nature of Light, and what it is.*

Their reasons which proue light to be a body.

BVt there are some make opposition; when wee say that the Light cannot moue the Sight because an incorporeall thing cannot change a corporeall Organ vnlesse it be disposed and fitted by certain *media* or meanes vnto that alteration, but light hath no actiue power beside illumination. I say against this some oppose and would proue that Light is a body: first therefore they

That light doth alter the eie.

retort our owne argument vpon vs. For as wee conclude that the Light cannot alter the visiue faculty; so they inferre on the contrary that it is therefore a body because it doth alter the eye; and that it doth alter the eye they conuince by experience, to wit, because the light doth trouble the eyes by mouing and tossing their spirites and so causeth some payne and griefe in them, which things cannot bee done without alteration which is proper vnto bodies; they therefore by good right conclude that the Light is a body.

Answere.

I answere (sayth *Placentinus*) that though a body be continually requisite vnto alteration, yet that alteration is not of the body as it is a body, but as it is such or such a body and so qualified; as for example; the fire doth heate not as it is fire but as it is hot: and as the heat it selfe doeth proceede from the fire and doeth alter cold things which are a good way distant from it, that is, make them hotte: so also the Light yssuing out of a lucide and cleare body doth trouble the eyes and produceth other effects aboue named. But as the heate of that fire is not a body but a quality of the body; so also it is not necessary that this Light be a body. VVe confesse therefore that alteration indeede cannot be made without bodies, yet this alteration is not to bee ascribed to the bodies but to the qualities of the bodies. In that therefore the Light doth alter the eye, it is not because it is a body, but because it is a quality of a body.

How light doth alter the organ of sight

This therefore maketh nothing for them which would haue the Light to bee the object of Sight: for the Light alters the Sight as it is a Light, that is, by illuminating, but this is not sufficient vnto Sight; for then heate, colde, humidity, siccity and other qualities should bee the obiects of Sight, because that all these doe alter the eye.

First reason of the contrary.

But beside these reasons there be almost innumerable others which doe conuince sufficiently that Light is not a body, and they are especially drawn from the conditions of bodies which doe continually and necessarily agree vnto them. For first of al, euery body is moued in a certaine time and successiuely, because of the resistance of another body; for one body cannot be mooued vnlesse it driue and force another which did before exist in

But the light is not so moued.

the place to which it is moued: for because Nature doth aboue all things abhorre vacuity or emptinesse, it must needs be that in euery place there must be a body. But the light not in any distaunce of time nor successiuely, but in a very moment doeth repleniſh the whole Hemisphere and Horrizon by a sodaine diffusion, and doth go through the whole space from the East vnto the VVest with out any progression of time; whence it doth necessarily follow that it is no body.

Secondly, euery body hath his proper circumscription and treble dimension, but this circumscription and these dimensions are not at all competent to Light, vnlesse you will attribute them to the light in regard of the body wherein it is, but then it doth agree thereto onely by accident.

To this we will adde that there is no body in Nature which is not diuisible into infinit parts; but who could euer deuide the Light.

Moreouer if it were a body some motion which bodies haue would agree vnto it; for all bodies are either mooued vpward or downward or circularly: but no such motion can be ascribed to the Light. It followes therefore that it is no body.

Againe, if it were a body it should bee either coruptible or incorruptible. But corruptible it cannot be, for then some thing should bee generated of his corruption, because the corruption of one thing is the generation of another, but nothing is generated of the corruption of the light, for if there were it would appeare seeing the light is so vast & immese. Neither yet is it incorruptible, for we see that when a Candle is put forth, the light is extinguished. But if we should graunt it to be a body, how would our aduersaries auoyde

Penetration of bodies impossible.

those absurdities which would follow there-from? Should not there bee a penetration of bodies? For the light doth penetrate all the parts of the perspicuous body, and yet the nature both of the light and of the body is preserued whole and entire. Seeing therefore that nothing is more impossible then this penetration of Diameters, as the Mathematicians

maticians auouch, it is alſo altogether impoſſible that light ſhould be a body.

Now that we know what this light is not it followeth that wee make inquiry what it is, which that wee may obtaine wee will make a reduction into the higheſt *genera* or kindes which are two. For whatſoeuer doth exiſt in the whole Vniuerſe is either a ſubſtance or an accident.

A ſubſtance this light cannot be, for it doth not ſubſiſt by it ſelfe, but if the lucide or bright body be remooued the light is alſo taken away: neither can it be ſeparated from the lucide body. Moreouer, no ſubſtance of it ſelfe is vnder the perception of ſenſe, but light is by it ſelfe perceiued by the ſight: and this no man can deny, becauſe it is neither knowne by Touching nor Taſting nor Smelling, nor yet by Hearing, notwithſtanding it is knowne; it remayneth therefore that the ſight doth iudge of it, and yet it is not therefore the obiect of Sight as we haue before ſhewed. What light is. Euery thing is either a ſubſtance or accident.

Seeing therefore the conditions of a ſubſtance doe in no ſort agree to light, it is neceſſarily inferred that it is an accident; which notwithſtanding many vncertain wits and ignorant do deny, grounding themſelus vpon this argument. That if it were an accident, then light would mingle it ſelfe with light in the ſame ſubiect, but it is not mingled, for there doth ſome diſtinction appeare betwixt the light of the Sunne and of a candle when they are both together. Obiection.

Secondly, they produce an example of two candles which make two ſhadowes out of one darke body; but if the light of the one ſhould be mingled with the other and ſo bee made as it were one, they would alſo make onely one ſhadow of one body. Second argument.

But it is not ſo as they ſay. For, that the light of the Sun is not mingled with the light of a candle, doth not happen becauſe it is no accident, but becauſe theſe two lights are not of the ſame kinde, for the one proceedeth from a body more pure and ſimple, the other from a more impure and materiall ſubſtance ſo that it ſeemeth after a ſort mingled with ſmoke; and as a pure thing vpon an impure rideth aboue and remaineth diſtinct, leaſt that which is immaterial ſhould be mingled with that which is materiall; ſo it is impoſſible that that the accidents of an immateriall thing ſhould bee mixed and confounded with thoſe which belong to a materiall body, and this is the reaſon why the light of the Sunne is not mixed with the light of a candle. Anſwer to the firſt. The light of the Sun is not ioyned with the light of a candle.

That which they add of two candles doth require another Solution; for the light of two candles is of the ſame kinde, but I vtterly deny that they are not at all mingled if this word *mingled* be rightly vnderſtood for any mixture or confuſion; for the light of one candle cannot be diſcerned from the light of another but onely by their ſhadowes; and for this I referre you to your ſenſes for the triall, becauſe we treate of a ſenſible matter; for take two candles and ſhew me the light of the one and of the other, thou ſheweſt the ſhadowes, and why? becauſe thou canſt not diſcerne the lights one from another. Anſwer to the ſecond.

But the reaſon why two ſhadowes do appeare, is, becauſe that the lucide bodyes doe ſend foorth their lights by right lines, and though their light bee mingled, yet they keepe the rectitude and ſtreightneſſe of their ownelines. When therefore a darke place is oppoſite to two lucide bodyes, it is of neceſſity that it ſend foorth two ſhadowes, not that the ſhadow is formed of the light, but becauſe the darke place is illuſtrated onely in that part where againſt the lucid body doth directly ſhine, otherwiſe hindring the light that it cannot reach vnto the backe thereof, which therefore caſts an obſcure ſhadow. So in the time of the Eclipſe when the Moone for want of light ſeemeth to faint away, this hapneth becauſe the light of the Sunne cannot attayne vnto her according to his wonted manner, be reaſon of the interpoſition of the earth betwixt them. For that obſcurity which is perceiued in the Moone is the ſhadow of the earth; for if the ſhadow it ſelf ſhould proceed frō the light; then at noone day when the horrizon is perfectly illuminated there could bee no ſhadow at all, becauſe there is no reaſon why it ſhould be made, rather on the one part of the obſcure body then on the other; nor why the light ſhould obſcure or caſt a ſhadow from one part of the darke body rather then from the other. Why there be two ſhadowes of two candles together. The ſhadow is not from the light from the darke body.

But to the matter; I ſay that the cauſe why there remayne two ſhadowes, although the lights do mixe together, is the ſtreightneſſe of the lines whereby the light is ſent from a lucide or bright body into a darke, ſo that it alwayes leaueth the hindpart thereof darke whence the ſhadow commeth. And that this is true it is hereby manifeſt, becauſe the ſhadow is mooued according to the motion of the lucide body, as alſo after the motion of the darke body which caſteth the ſhadow. So that alwayes there is a ſhadow at the backe part The ſtreightneſſe of the lines is the cauſe why there be two ſhadowes.

and

and that which lieth oppoſite by a right line againſt the lucid body is alwaies enlightened. Yet theſe two ſhadowes will not be ſo obſcure as if there were but one, becauſe either of them is much illuſtrated by the light of the other lucid body by which it is not produced. And ſo much of the nature of Light.

QVEST. XXXI. *Of the difference betwixt Lux or Light it ſelfe, and Lumen or Illumination.*

That they differ in kinde.

THoſe which do peremptorily perſiſt in the defence of the intentionall or imaginary eſſence of light, hold that *Lumen* or the Illumination and enlightning is a ſpecies or kinde of that we call *Lux* or the *Light*. For, as the *colour* and the *ſpecies* do differ in kinde, ſo in like manner dooth the light it ſelfe differ from the *Lumen* or enlightning, becauſe as colours by their ſpecies becomme ſenſible, ſo the light is ſeene by the illumination of it as by his ſpecies or forme. But we conſent not with them: for if light were ſeene by illumination, then this illumination would not fall vnder the Senſe; for the ſpecies of ſenſible thinges are not themſelues perceiued but they are that whereby the obiects do moue the Senſe; ſeeing then the *Lumen* is ſeen by it ſelfe it cannot be that the Light ſhould through it attaine vnto the Senſe.

This opinion improoued.

Obiection.

But they further obiect, that the *Lumen* or enlightning is in a tralucent bodie, and the light or *Lux* in a darke bodie, and that therefore they differ *in ſpecie* or in kinde one from another. But I anſwere that it is not ſo; indeede we grant that the *Lumen* is in a tralucent or bright bodie, but we confidently denie that the light is in a darke bodie, for it is alſo in a tralucent body, yet in a ſubiect more denſe and darke then that of the *Lumen*, for the light it ſelfe is more darke then the illumination: therefore ſaith *Ariſt.* it doth determine or limit the ſight, whence it hath the name of a colour. For hee calleth light white in the booke *De ſenſu & ſenſili*, and alſo in the fourth chapter of his firſt booke of Meteors hee calleth the Sun white. But the matter is cleere of it ſelf, for we perceiue that our ſight is terminated in a flame, in the Sun, or in the Moon, neither are any other colours brought vnto vs through them.

Solution

Obiection. Anſwer.

But it may be obiected that light ſeemeth to be permanent and abiding in the ſubiect, but the *Lumen* is not except in ſome cleare, bright body. I aunſwere it is true, but yet this doth not argue a ſpecificall difference: for as the heate being proper vnto the fire doth abide therein, and the other heate which is produced from this dooth vaniſh when the fire is remooued from it, yet they differ not in kinde, ſo neither doth *Lumen* or enlightening differ from *Lux* or the fountaine of this Illumination.

That *Lux* and *Lumen* do not differ in kind

But there be many reaſons why they do not differ in kind one from another. For ſometime the *Lumen* or illumination dooth aſſume to it ſelfe the nature of *Lux* or Light. So the Moone hath light which is manifeſtlye nothing elſe but the very enlightning of the Sun. But do they not at all then differ? I ſay they differ, yet in the Planets not truely but onely in reſpect. For example, the Moone as it doth enlighten the earth hath Light, but as it receyueth this light from the Sun it is onely an illumination; and hence it is that ſome illumination hauing a conuenient dark body oppoſed to it will becom light & ſend an illumination out of it ſelfe: But if you let it bee without a darke body it will be onely an illumination. Euen as the Elementary fire in his proper place is commonlye called *Lumen* and yet is not ſeene becauſe it hath no darke body, that ſo it may tranſmit her illumination to vs, ſo that light is no other thing but a condenſed illumination, yet not ſo that it doth degenerate into a colour.

Why the elementarie fire is not ſeene.

Moreouer, they differ in the ſubiect. For this *Lumen* or illumination in his proper ſubiect is *Lux*, that is, a Light; but being without it, it is a meere illumination, that is, Light is properly called that which is in a lucide or bright bodie, as in the Sunne and in other Starres; but illumination is that which is produced from the light, ſo that in the ſun there is not illumination but light, and in the aire there is no light but *Lumen* or illumination onely.

QVEST.

QVEST. XXXII. *That colour is the Obiect of Sight.*

ALL the Authors which euer writ of the Sight, haue determined with one consent, that colour is the proper Obiect thereof, herein following the steps of *Aristotle* who hath beene their leader and guide. For in the beginning of the seuenth Chapter of the second book *de Anima*, he writeth on this manner. *That which is visible is colour, and this colour is that which is in it that is visible. And it is visible* per se, *or by it selfe: that is to say, it hath the cause within it selfe which makes it visible.* Where he not onely describeth the common Obiect of Sight: but doth presently after restraine it vnto a proper Obiect; to wit, that which hath the cause of visibility (if I may so say) in it selfe: but the cause of visibility is to bee able to mooue the *perspicuum* or tralucent body, that is to imprint his Species in the *perspicuum*, by the meanes whereof the Sight is moued, and therfore he addeth immediatly these words. *All colour is motiue, or able to mooue that which is actually tralucent, and this is the Nature thereof.* If therefore the colour doe by it selfe moue the transluced body, which is the proper cause of visibility, it must also bee accounted necessarily for the proper Obiect of Sight. For neither illumination, nor light, nor any other thing by it selfe can moue this Sence, vnlesse in some part it be answerable vnto colours, and then the effect is neuertheless due vnto the colour.

Colour is the proper obiect of Sight.

Arist. authority.

Adde hereto, that the proper Obiect of Sight must be of that nature, that in it the Sight may be determined; and may rest to forme the visiue faculty; and wherein if neede require more accurate inspection, it may stay and rest it selfe. But no such thing can bee found in the whole frame of Nature besides colours.

Another reason to proue it.

Againe, by the Obiect of Sight all mixt bodies doe become visible, but this is accomplished neither by illumination nor light, nor by any other thing, but onely by colours, and therefore they are the proper Obiect of Sight. It is true indeede that things are made visible in the light, yet not by the light, that is, light is no sufficient cause of vision, because it is not able, nor apt to moue the tralucent body, but onely the forme of the *perspicuum*, for when we say that colour is able to moue the *perspicuum*, we doe not vnderstand that it is the Act of it, but that it affects and moues it by a visiue *species*, and this is peculiar to colours alone.

3. Reason.

Lastly, all things which be visible do fall vnder the sight of the Eyes, by the accidents which are in them; after the same manner whereby wee attaine to the knowledge of any thing by another quality; but neither illumination, nor light, nor any thing before mentioned is in visible things but onely colour, therefore wee knowe not thinges by them but by the colour.

Seeing then that the obiect of Sight ought to be such, that thereby we may come vnto the knowledge of visible things, none of these but onely colour is to be accounted the obiect of Sight, for this is in all things and doth immediately follow the mixton of Elements.

The variety of kinds is required in euery thing.

I might adde that in euery obiect there are diuers *species* to be required, as contrary, intermediate and some alike, because there is no election, choyce or dignotion of one simple thing. But there are no differences of Illumination nor Light nor of other thinges which wee haue rehearsed, much lesse are there contrarieties. For illumination doeth not truely differ from illumination, nor Light from Light; neyther is illumination contrary to illumination, nor Light to Light; but there are diuers differences of colours and one colour is contrary to another; not those therfore but this, to wit, colour is the obiect of sight.

QVEST. XXXIII. *Whether Colour be Light.*

Of one faculty must there be one obiect

BEcause Light as wel as Colour doth determine the Sight, and hath in it selfe a cause of visibility, hence some thinking that there ought to be but one obiect of one knowing and discerning faculty, haue esteemed Colour & Light to be of the same Nature. But this cannot bee, for all Colour is not Light, neither is all Light Colour; whereas if they had beene of the same Nature, they might haue beene conuerted reciprocally.

But they vrge thus. *Euery thing which is seene is colour, but Light is seene therefore Light is colour.* I answere, to bee seene may bee vnderstoode two wayes: first commonly and improperly, so as euery thing both colour and that which is proportionable thereunto is sayde to be seene. And so *Aristotle* taketh it in the 2. Booke *de anima*, and his Chapter *de*

visu, where in the beginning he sayeth *That which is visible is colour, and that which is without name*: as if he should say, *That which is proportionable vnto colour*: and after this manner Light is seene and yet is not therefore a colour, becausse that on this manner many things may be seene which are not colour, but onely proportionable vnto colour.

Secondly, this word *Seeing* is taken properly, and according to this acception nothing can be seene besides colours.

Obiection. But they add yet further that the same effect belongeth to the same cause; but whitenesse and light do performe the same effect, for a white colour doeth dissipate the sight and weary the Eyes, and the same effect doth the light worke, wherefore light and a white colour doe not differ.

But we deny this argument. For though there be great affinitie and likenesse between whitnesse and the light, as also betwixt blacknesse and darkenesse, yet no Identity nor vnity of the species or kind doth hence ensue; for if the case were so, two lucid bodyes would produce colours of two kinds in one and the same darke body; becausse they can neuer shine equally and alike: but to shine were to send forth a colour. Againe, when the light faileth, that is, when darknesse begins to come; first a greene colour, then a purple and so other intermixed colours must bee induced vppon the darke body till at length it attaine vnto the quite contrary colour, to wit, blackenesse; euen as the light doth mediatly and by degrees degenerate into darkenesse. But nothing can be more absurd then this; for wee see that a white colour remaineth white, vntill the least part of it may bee seene, yea it abideth white til it be so dark that we can see nothing, & all colours are taken away from our eyes.

That colour is an illumination. Others with more shew of truth haue vndertaken to perswade that colour is *Lumen* or an illumination, which opinion they strengthen with no small arguments. First, becausse when this illumination is absent colours cannot be present, and againe, at his arriuall or returne they are generated in the bodyes.

But this argument is of small force, for *Lumen* or illumination doeth not generate colours in bodies; neither when it departeth doeth it take them away, but is onely the cause wherefore they are rather sensible when it is present, and being absent they are not seene. The reason is becausse without this splendour colours cannot moone the tralucent bodie, and so the night doth not take away the colour but the images of it which are as it were the deputies or instead of the colours: but the reall colours which are by themselues visible doe remaine, if not actually yet potentially.

Yet they vrge further: that we see by experience that the cloudes by the diuers irradiation or glittering of the Sunne sometime are of a white and sometime of a red colour: as also is the Rainebow: for which cause also we see the Sea sometime to waxe purple coloured, sometime to become gray, and a farre off to shew white, and at hand blacke. Finally, the necks of Doues and the tayles of Peacocks doe wonderfully varry their colours by the diuers aspect of the Light. But none of these are thus indeede and in trueth, but doe so appeare by reason of the vehement splendor of the Sunne or of the leuity of the coloured bodie; whereuppon the Sight is somewhat hindered that it cannot discerne off and know the reall colours as they are.

Againe, this hapneth not only from the direct or indirect irradiation of the Sunne, but also from our beholding of the coloured thing from on the right hand or from on the left, forward or backward. For it is greatly to be respected whether the shadow of the coloured thing bee on our side or on the opposite: and therfore according to the motion of the Peacocke so the colour of her trayne seemeth to be varried: which thing Painters when they goe about to Limne any picture doe diligently obserue, marking the place wherein the life is placed: to wit, in what part it doeth receiue the light. Moreouer, they consider the entraunce into the place where it is, that they may resolue on what part they may best behould it: well knowing that both our eye and the light should bee well disposed vnto the right perception and discerning of the reall colour. For if a well painted picture be placed in an inconuenient place his forme will not appeare artificial but deformed and disordred, not that it is so indeed, but that it onely appeareth so by reason of the inconuenience of the place. And thus also it is with the colours of Peacocks, so that hence wee are taught that the illumination doeth not alter the colours, but the disordered scituation of the coloured body and of him which beholdeth it, are a great cause of the variation thereof.

A good obseruation of Painters.

QVEST.

QVEST. XXXIIII. *That the pure Elements are not coloured of themselues.*

Perspicuum or Tralucent bodie being without all darkneſſe can neuer be ſo condenſed that a colour ſhould ariſe therefrom, and therefore the ſimple Elements, yea and the heauen it ſelfe haue abſolutely no true colour: for though the aire may be ſo condenſed that it may degenerate into Water, yet it will neuer attaine vnto a colour, no nor the earth it ſelfe, nor yet that which is more condenſed then the earth. They therefore bee in an error which aſcribe whiteneſſe vnto three Elements and blackneſſe vnto the Earth: Indeed perſpicuitie and tranſparencie may be allowed to theſe three and a kinde of darkneſſe to the earth, but no colour at all. Notwithſtanding they prooue that colours do agree vnto the Elements, & eſpecially ſimple colours as white and blacke; becauſe they be ſimple, and as a mixt bodie is made of the mixture of the Elements, ſo say they from the mixtion of white and black mixt colours are generated. And this is their argument: *That which agreeth to any thing by participation, doth alſo agree to it by eſſence; but both extreme colours and thoſe which be intermixed do agree vnto mixt bodies by the participation of the Elements: whence they conclude that it is neceſſary that ſimple colours, that is, white and blacke do eſſentially agree vnto the Elements.* To which we will anſwere by denying the maior propoſition, for many things do belong to a bodie by the participation of another, which may not bee attributed to that body as it is abſolutely conſidered. So to the Elements which are here with vs very turbulent and confuſed many thinges doe agree, which no man of vnderſtanding dare aſſigne vnto the ſimple and ſincere Elements.

The pure Elements are not truly coloured

Obiection.

Reſolution.

As for example, Our fire which is nothing elſe but a certain kindled and flaming ſmoke, is coloured perſpicuous and bright, yet the elementary fire we imagine to be pnre & moſt ſubtle, from which as from a Fountaine ours dooth flowe, yet hath none of theſe groſſe qualities which our fire hath. For being exceeding ſubtle & fine it hath no ſolid ſubſtance admixed with it, and therfore is not affected with any colour, neither is it lucid and tranſparant. For colour conſiſteth in ſuch a bodie as doth determine the ſight, but light doth not ſhine in a ſubtile and thin body, but in a denſe or thicke body: we grant therefore for the preſent, that in mixt bodies colours do reſult or ariſe out of the concurſion of the Elements, yet it doth not thence follow, that elements being pure and not defiled with the ſtaine of other compounded matters ſhould be tainted with ſuch colours as are ſaide to be in the extremities of bodies, as accidents are in the ſubiects; becauſe the ſecond qualities ariſe from the firſt which to aſcribe to theſe ſimple bodies wer very eroneous: Wherfore the Elements do not primarily generate colours in mixt bodies but ſecondarily, that is, not as they retaine their proper Nature but as they lay it aſide, and ſo do conſpire into the nature of the mixt bodie. For the Elements cannot concurre in one and ſo make a mixt body vnleſſe they ſuffer an alteration both according to their ſubſtance and according to their quality, & ſo they do as it were put off their proper being or eſſence, that by this mutuall embracing and coniunction they may produce a compound body. If therefore they neither retaine their ſubſtance nor their firſt qualities (which the ancients eſteemed as their eſſential forms) how ſhould they reſerue entire to themſelues thoſe colours which are their ſecond qualities that the colour of the mixt bodie ſhould proceede from a confluence of the colours of the ſimple Elements: wherefore colours do belong to mixt bodies primarily and by themſelues, that is, eſſentially and not by participation, and ſo we will paſſe by this argument, not medling with the ſophiſtry of their Sylogiſme, which euery one that runneth may perceiue.

How the Elements generate colours.

QVEST. XXXVI. *Of the generation of Colours and of their forme.*

We haue determined already that true colours are produced from the Elements mixt among themſelues and not from their firſt qualities, to wit, the heate, cold, humidity and ſiccity as ſome haue thought, though indeed almoſt all ſecond qualities do conſiſt of theſe; but colours doe ariſe from the eſſentiall forme of the Elements, from which forme (as it were a proper accident) they are deriued, that is, colour dooth ariſe out of the perſpicuity and opacitie of the elemenrs proportioned together. For three of the Elements be perſpicuous, the Fire, the Aire and the Water, yet ſo that the Fire is more tranſparant then the Aire, and the

The originall of Colours.

Aire then Water, onely the Earth is darke: when therfore the Earth is mingled with the three other, it doth determine their perſpicuity and ſo induceth a colour into the mixt body, for their tranſparency and perſpicuity is condenſed and made more craſſe and thicke, ſo that they ceaſe to be tralucent and do determine the ſight, and then colour neceſſarily followeth. For to terminate the ſight in his ſuperficies is to be coloured, becauſe nothing can determine the ſight but by ſome colour: A colour therefore ariſeth from the condenſation of a tranſparant bodie by that which is darke in the miſtion of the Elements; for when the tranſparant body by reaſon of the darke body ceaſeth to be tranſparant, it becommeth coloured and in his ſuperficies doth mooue the ſight.

That which determines the ſight is coloured.

Colour is generated of the miſtion of the darke bodie.

Hence appeareth their errour who ſuppoſe a double nature of colour is ſignified in that definition which we haue giuen, ſeeing *Ariſtotle* cals it *The extremity or outſide of the tranſparant body*; for the extremity of the tralucent body is not a color, but that which like attacident doth inhere in the extremity or ſuperficies; or if you will, the extreame outſide of the *perſpicuum* or ſplendent bodie is not the cauſe of the colour, but the colour produced from elſwhere doth by his adumbration or circumſcription determine the tranſparant body. For the *perſpicuum* or tranſparant body is that, which by reaſon of the tenuitie of his parts doth tranſmit the light and ſo appear, yet doth not determine the ſight; where therefore the Sight is determined, there the *perſpicuum* muſt end: for except it were ſo the ſight would yet proceede further beyond it; but the Sight is terminated onely by colour and therefore colour is rightly called the tearme or bond and extreamitie of the *Perſpicuum*.

VVhat *perſpicuum* is.

Of the Forme of Colours.

Many are of opinion, that there be no colours in the darke but onely a kinde of faculty and beginning whereof colours do ariſe as it were out of a matter illuſtrated by illumination which ſerueth in ſteade of the forme: Of which Sect *Epicurus* was as *Lucretius* ſayth.

Praterea quoniam nequeunt ſine luce colores
Eſſe, niſi in luce exiſtunt primordia rerum.
Scire licet, quo ſunt quenis velata colores,
Qualis enim cæcis poterit color eſſe tenebris?
Lumine qui mutatur in ipſo: propterea quod
Recta aut obliqua percuſſus Luce refulget.

Againe, becauſe no Colour can without the Light appeare,
VVho ſhall diſcerne what coloured maskes the Elements do weare
Vnleſſe the Light do vnto him their ſeuerall hewes bewray?
And what man can the colours blaze which in blinde darkeneſſe ſtay?
Becauſe in Light all colours change, and ſhine as they are ſmit
With the Oblique or direct Rayes which from the Light do flit.

And hee maintaineth his opinion by this, that as the coloured bodie is illuminated either rightly or obliquely, euen ſo are the colours thereof changed. But hauing diſputed this before I now paſſe it ouer, ſo that it remaineth that we demonſtrate and ſhew that the *Lumen* or ſplendencie cannot be the forme of a colour. But firſt let vs heare the Argument which the *Epicures* bring in defence of their opinion. They ſay therefore that *Seeing the Faculty of Seeing is one and ſimple, therefore all thinges which are iudged thereby properlie and by themſelues ought to bee referred vnto* One primarie genus, *and becauſe Light cannot bee reduced vnto colour, it is neceſſary that colour be reduced vnto light.*

The Epicures reaſons that Light is the forme of Colours.

But this reaſon is ſo abſurd, that it ſeemeth not worthy the time and labour of confutation, eſpecially becauſe it no whit aduanceth the certainty of that which is in controuerſie. For they were to conclude, that *lumen* was the forme of colours, yet neuertheleſſe their argument will not ſtand; for we graunt indeede that that which is ſeene, ought properly and by it ſelfe to be reduced vnto one *genus* or head, becauſe the faculty iudging of them is one, as we haue proued before; but wee denie that illumination can properly be ſeene, or that colour may be referred there-vnto. Haue we not conuinced by that which goeth before, that whatſoeuer is ſeene by it ſelfe is a colour? Are not light and tranſlucencie perceiued improperly, to wit, onely as they are proportioned vnto a colour, as wee haue proued ſufficiently? And haue we not demonſtrated that neither light nor ſplendencie can be a colour? How then ſhall colour bee brought vnto the nature of light? Yea, I

All the Obiects of Sight ought to bee reduced to one head.

maintaine

maintaine the contrary, to wit, that illumination may and ought to bee reduced vnto colour, becauſe it becommeth viſible no other way then as it obtayneth ſome proportion with colour. The light is referred to the colour.

But in the meane time ſome doe obiect, *that Colour is ſaid to be actually the extremitie of the tranſparant body, that is, not of the tranſparant body as it is tranſparant, but as it is an illuminated tranſparant body; becauſe without light both the colour and tranſparant body are only in* potentia *and poſſibility. Seeing therefore that the light doth enduce an actuall being vpon the colour, it will follow that light is the forme of colour, becauſe the act of a thing is the forme of it.*

How that of *Ariſtotle*, namely that colour is the extremity of the tranſparant body, is to be vnderſtoode, wee haue ſhewed before, but where it is ſaid that light doth actuate colour, I anſwere, that light doth not actuate the colour as it is conſidered in it owne Nature as a colour, for a colour remaineth a colour euen in the darke: it is true indeede that it maketh the colour actually viſible, neither doe we denie it; but if it were the forme of the colour it ſhoulde not onely make it viſible, but what Eſſence ſo euer colour hath it ſhould of neceſsity haue receiued it from the light: but we haue taught already that the whole Eſſence of colour proceedeth from the foure Elements. Light is not the forme.

Moreouer, it cannot be that this Light ſhould be the forme of colours. Firſt, becauſe the forme ioyned with the matter doe conſtitute one compounded body: but light and colours are in diuers ſubiects. The reaſon thereof.

Againe, who euer ſaid that one accident was the forme of another? but light though it be ſomething more then a meere accident, yet it ſauours moſt of an Accident, and therefore cannot be the forme of a colour.

Laſtly, if Illumination were the forme of colour, then colours ſhould not differ in *Specie*, for whether the light be ſtrong or remiſſe, whether it be direct or refract and broken it is alwayes of the ſame *Species*, but we ſee that colours be not onely diuers but alſo contrary, therefore light cannot be the forme of colours.

But the Epicures would make vs beleeue, that this variety of colours proceedeth from their different originals and beginnings which they eſteeme to be their matter. Surely, an opinion vnbeſeeming one which carieth but the name of a Philoſopher, for can you take the differences of things from their matter? Know you not that the ſpecificall difference of things doth flow from the forme? Is it any matter which diſtinguiſheth a man from a beaſt? No: but the vnderſtanding or reaſon. Now reaſon is the forme of a man, not his matter. And this wee may learne by mechanicall Arts, for the ſame workman out of the ſame matter doth forme both an Altar and an Image, and theſe differ one from the other, not becauſe they conſiſt of a diuers matter, but becauſe a diuers forme is giuen to either of them. All difference is taken from the forme.

To theſe we will add, that Colours are another thing then the light. For colours work vpon the light touching the illuminated aire; as may appeare in a Looking-glaſſe receyuing colour brought vnto it through enlightned aire; ſo alſo the greenneſſe of Trees and Medowes doth appeare in ſuch bodies as are oppoſite vnto them, which could not be except the colour ſhould worke vpon the Light; but who euer ſaide that the things formed did worke vpon the Forme? How a glaſſe receiueth Images.

QVEST. XXXVI. *Of the Medium or Meane of the Sight.*

NO man euer doubted whether the Sight ſtoode neede of a Meane, but all reſt vpon experience, which no man well in his wits will contradict: For if you lay any colour vpon the Eye it will not bee perceiued; and if that ſaying of *Ariſtotle* be true in any Senſe, it is eſpecially true in this Senſe of Sight, to wit, that *the ſenſible thing being laide vpon the Senſe doth make no Senſation.* Therefore wee ought not to doubt that the Sight hath neede of a *Medium*, eſpecially being here-vnto perſwaded by reaſons beſides experience. For Sight is a ſpirituall Senſe, and therefore cannot perceiue materiall things as they are materiall, but it diſcerneth their *ſpecies* receiued in the Meane, and how could materiall things ſend forth theſe *ſpecies* if there were no *meane* betweene the Obiect and the Organ: I ſay if there were not a *Medium* which might draw out and receiue the *ſpecies* or formes. A viſible Obiect impoſed to the Eyes is not ſeene. The reaſons why it needeth a *Medium*.

No bodie is the Meane of Sight. Neither compound

It remaineth therefore that we make inquiry what that is which is a competent *medium* in the Senſe of Seeing. Firſt, it cannot be a body; for euery bodye is either Simple or Compound. A compound body it cannot be, becauſe all compound bodies bee coloured and by conſequent are an *Obiect* and not a *Meane*; neither can any of the ſimple bodies be accounted for a *Meane*, for they bee the foure Elements, Fire, Aire, Water and Earth.

Fire is no *Medium* for we can ſee without it, nor yet the Aire becauſe we can ſee Obiects which are in the water, and this is the reaſon why the other Elements are not fit for this function, for a true *meane* muſt be in the middeſt betweene all viſible thinges, but the Elements are not ſo, no nor the heauen it ſelfe. It followes therefore that none of theſe may be accounted for the *meane* of ſight.

Nor Simple. Perſpicuity is the true *mean* of Viſion.

It is therefore ſome accident which we muſt reſolue vpon to be this *Medium*, as appeareth by that which we haue ſaide; and all men do with one conſent acknowledge this accident to be Perſpicuity or Tranſparancy, ſo that we need not to doubt thereof. But becauſe this Tranſparancie as it is an abſtracte and an accident is not ſufficient for the performance of this function, for that the obiects doe require a certaine definite affection in the *medium*, that ſo they may be carried to the Inſtrument, whereby the conſent and agreement may bee preſerued, and that there may bee a Connexion and knitting of the extreames, to wit, of the Obiect and Organ by the Meane. We muſt therefore finde out what it is that doth aſsiſt and helpe this perſpicuity. And this is nothing but the ſubiect of it, ſo that we do not admit ſimply the perſpicuity but the perſpicuous bodie as it is tranſparant for the true Meane of the Sight, that is, not the abſtract onely but the whole concrete as it hath perſpicuity in it, ſo that wee are to conſider in it both his Matter and his Forme.

Not perſpicuity but the perſpicuous body is the Obiect of Sight.

The *Etimon* of *perſpicuum*.

The matter of the tranſparant body is not one and the ſame but diuers and manifolde, I ſay, euery thing which is peruious and may be perceiued without obſtacle or reſiſtance, for the *perſpicuum* ſeemeth to be derived *a perſpiciendo* or perceiuing, as a tranſparant bodie *a tranſparendo* becauſe all things do tranſpare and appeare through it. It is therefore nothing elſe but a kinde of ſubſtance, not craſſe nor denſe, but thinne, rare and ſubtle, and eſpecially apt and fit to receiue the Illumination and the colours of other things, as are the Aire and Water and alſo many other ſolide bodies, as Glaſſe, Ice and ſuch like, as the Philoſopher witneſſeth in the 68. Text of his 2. booke *De Anima*.

QVEST. XXXVII. *Whether Light be the Forme of that which is perſpicuous.*

Whether the *perſpicuum* periſh with the light.

WE haue taught before that Illumination is the Forme of the perſpicuous bodie, but becauſe the light doth very eaſily recede and goe away ſo that darkneſſe doth ſucceed and eaſily returne, it may worthily be called in queſtion, whether at the departure of the light the perſpicuous body doth alſo periſh and ceaſe to be, and is againe generated with the returne of the Light or Illumination.

The *perſpicuum* is potential in the darke.

For my owne part that I may ſpeake ingeniouſly, I am perſwaded that it is not corrupted wholy, but onely after a ſort ſeemeth to periſh, for whatſoeuer is depriued of his eſſentiall forme is ſaide to periſh. It ſeemeth therefore that the perſpicuous body may bee ſaide to periſh when at the receding of the light darkneſſe doth enſue: which darkneſſe is a priuation of that light which was the eſſentiall forme of the *perſpicuum*, I ſpeake of a bodie actually perſpicuous, becauſe the action, or if I may ſo ſay, the actuality of it ceaſeth when the light fadeth, yet notwithſtanding it remaineth in *potentia* or in poſsibility: for the enlightning dooth not induce any ſubtilty or tenuity of the ſubſtance: and whatſoeuer is thus perſpicuous is alſo potentially perſpicuous in the very darke, for ſometimes darkneſſe ſometimes light are in perſpicuous bodies, as *Ariſtotle* ſaith in the 69. Text of the 2. Booke *De Anima*, where he defineth a potentiall perſpicuous body.

A Doubt reſolued.

But there is yet another doubt of greater waight. For becauſe the Light is an accident, to witte, a quality proceeding from the lucide body, how can it bee the forme of the perſpicuous body, in regard that to bee a Forme of any thing is peculiar to a Subſtance? How then can that giue any eſſence or being to another which hath no eſſence at all of it owne, for the Light hath no beeing of it ſelfe but doth perpetually depend vpon the Lucid bodie, and therefore how ſhould it giue an eſſence to the *perſpicuum*? I grant indeede

Anſwere.

that

that the light may bee called a quality of a lucide body, yet I denie that it is nothing but a meere accident. For all accidents haue their being in some subiect, and out of the same are nothing: but *Illumination*, though it doe depend perpetually vpon some lucide body, yet it doth exist out of it, and doth onely in respect differ from that *Lux*, which is as it were the fountaine of it as before we haue shewed, and wee see that this Illumination is diffused through the whole Hemisphere, which could not be if it were a mere accident, & had no proper Essence of it owne; for no accident doth spread so farre from his Originall or Subiect.

The essence of an accident is in another.

Light is not a meere accident.

VVe say therefore that *Lumen* out of the lucide body hath a certaine proper being of his owne, and in that regard is sayd to be the forme of the *perspicuum* or transparant body, for which cause some call it *The imitation or resemblance of a lucide body in a perspicuous medium.* But as it is in the lucide body and doth depend vpon it as vppon his originall, it is not without some reason called a quality of the same lucide body.

How the light is a quality.

But some argue against this on this manner: That the light cannot be the forme of the *perspicuum*, because it also receiueth the darknesse into it: if therefore illumination be the forme of it, then that which is contrary to it, to wit darknes, would in like manner supply the place of a forme, and so one thing would haue two formes.

Obiection.

But the consequence is false; for though the perspicuous body doeth receiue as well darknes as light, yet not after the same manner, for it receiues the one as his forme, the other as the priuation of that forme; Light as his Act, and darknes as the priuation of that Act.

Solution.

For darknesse is not contrary to light but a priuation of it, and indeede no other thing but an absence of Light from a subiect which is fit for illumination.

What darknes is.

But *Auicen* sayth that the Light is not receiued in a perspicuous but in a darke body and coloured, which body when it is outwardly illustrated, then hee thinks that the perspicuous body is illuminated, and hee would haue this perspicuity to note nothing else but a priuation of that which hinders the Light, & then that *perspicuū* is present when there is nothing to hinder the colour that it might not be illuminated. If then the Light bee not receiued in the perspicuous body, it cannot by any meanes be the forme thereof.

Auicens opinion.

But though there bee many learned men of this opinion, yet I cannot stay my iudgement vpon it for some perswasible reasons which mooue mee to thinke contrary. For nothing can passe from one extreame vnto another, vnlesse it passe by the mean which is betwixt them; and it cannot passe through the *Medium* vnlesse it be first receiued into it. Moreouer in a perspicuous *Meane* there appeare diuers effects of Light; for it is attenuated and heated, which could not be if the Light were not first receiued into it. And by this we may easily gather the insufficiency of *Auicens* conceite. Thus much concerning the difficulties about the Eyes. Now let vs come to the Sense of Hearing.

Refuted.

QVEST. XXXVIII. *Of the Production of a Sound.*

Aristot'le in the first Chapter of the fourth booke, and in the sixt Chapter of the sixt booke of his *Topicks* saith, that the knowledge we haue of any *species* dependeth vpon the knowledge of the *Genus*. Seeing therefore that the voice is a certaine *species* of Sound, and as it were an ofspring propagated there from, it must needes bee that it sauour much of his originall and beginning. Wherefore before we come vnto the knowledge of a voyce, which is the most particular Obiect of the Sense of Hearing, it is very necessary that we præmise somewhat concerning the production of a Sound in generall, for by that meanes our knowledge of this Action of the Soule, I meane the Sense of Hearing will bee better guided and perfected.

Why the production of a Sound must goe before the definition.

Wherefore we will first shew you the manner of the production of a Sound. Secondly, the definition of a Sound. Thirdly, the differences of Sounds. And lastly, we will vnfolde some difficulties which may otherwise breede scruple in vs. I know well that in other things the playnest way of teaching is to beginne with a definition, but because a Sound, is as wee say *ens fluxum*, that is, such a *being* as is then onely existent while it is a doing and in the time of his generation; it must needes follow, that when the generation or manner of production is sufficiently knowne, the nature and definition will bee better vnderstoode.

Hence it was that *Aristotle*, when hee would deliuer the Nature of a Sound, began his Treatise

treatise at the maner of production, & so will we, insisting in his footsteps, which although we cannot attaine vnto yet we will a farre off adore.

3. Things required to the production of a sound. Two bodyes. A *medium.*

As therefore no sound is made without two bodyes mutually impeaching or offending one against another, as euen our Sight and Hearing doe sufficiently teach vs, so our minds also may conceiue that without the mediation of a third thing which should be not onely the *medium* wherein a concussion is made, but also the materiall cause hauing in it a *power* of sounding materially, there can no sound at all by the concussion of those bodyes be produced.

The necessitie of this *medium* or third body which must come betweene in the collision of 2. hard bodies which make a sound may be thus demonstrated. If two bodies meet one of them must moove and apply vnto the other. Now we know that motion cannot be made without a *medium.* Againe, that this *medium* or third body must haue the faculty of sounding materially therein, is prooued, because though two bodyes offend one against another, yet if they be sharpe or soft they make little or no sound at all, so a Needle against a Needle, wooll against wooll doe not sound. The reason of the first is, because there is no quantity of this intermediate matter to make an impression off; the second, because though there be a collision yet there is no resistance.

Many instances to proue that there must be a *medium.*

Moreouer, things that are vnequall or rugged doe not sound well, neither doth a plaine thing make a full sound, for the more cauity there is in the body that is beaten (so it be proportionable to the violence that is offered) the more resonant is the sound. Add hereto, that sometimes though the collision be with greater violence, yet the sound is not so loude, for two blockes beaten together will not make so loude a sound as a little bell; and when a new peece of cloth is torne a sunder, the rash is louder then if two harder bodyes should enterfaire one against another. All these instances doe manifestly proue that there is a third thing requisite vnto the production of a sound, which is also the matter thereof.

This third intermediate body is that wherein the concussion is made, be it Ayre or Water, or Fire, for those three bee not onely fit for the transuection of sound, but haue also in them the matter whereof it is formed, although not in an equall degree.

In concussions therefore the faculty of the *medium* or power of the matter is actuated when it is intercepted and broken betweene two bodyes offending one against another.

The maner of the fraction

The manner of this interception or fraction is thus; when two bodyes strike one against another, that which is betwixt them is so vehemently driuen, that one part of it cannot orderly moove by succession after another, but rather one part preuents another, and before the first part hath parted from the place another is driuen vpon the necke of it, and so the motion which when it is successiuely made, is gentle and easie, becommeth now by reason of this inordinate violence tumultuary and troublesome. Hence it is that soft & acute bodyes make no sound in their collision, because the stroke that is betwixt them doth not so disparkle or diuide the intermediate body that there should follow vpō it any interception or fraction, whereby the successiue dissipation may be preuented. Vnequall bodyes because in their hollow and depressed parts they diuide the Ayre as it were into parcels doe yeeld a lesser sound. Those that are hollow because they gather and close more Ayre which is confusedly shuffled and beaten part vpon part, do yeeld a greater and stronger resonance? Two blocks beaten one against another do not sound so loud, the reason is because the fraction is not so smart; a bell and a clapper because of their hardnesse and polished superficies doe breake the Ayre more suddainly and throughly, and so beget a louder and brisker sound. A new cloth when it is torne a sunder rasheth louder then the percussion of a harder body, because the Ayre which is about it is diuersly distracted into many parts where the manie threds are torne a sunder.

According to the differences of the former instances

It remaineth therefore that a sound is made when as two bodyes offending or iustling one against another, the *medium* wherein they are mooued endureth betwixt them a compression, that compression endeth in attrition, that attrition in fraction, and that fraction kindleth as it were at resonance.

That the fraction is not the sound.

VVherefore, *Aristotle* sayde well in the 78. text of his second booke *de Anima* that a sound is alwayes actuated *when one thing moues against another in a third.*

But although the ayre thus beaten and broken makes a sound, yet the very fraction of the ayre is not the sound neither the next and immediate generation thereof, and herein all

all Philosophers doe agree, particularly *Auicen.* But what shall wee stand vpon authorities, we prooue it thus.

The fraction of the ayre is a motion but the sound is not a motion; First, because a Sound is the proper obiect of the Sense of Hearing, but Motion is a common obiect not discerned by the sense of Hearing, and therefore a Sound is not a Motion.

Secondly Motion is no quality but reduced vnto other *Predicaments* as wee say in Schooles, that is, to *Action*, *Passion* or *Place*. But Sound is a quality, to witte, one of the third kind to which the obiects of the Senses are referred. Nor the motion.

Thirdly, Sound is made by Motion; so we see by experience, so wee are taught by all Philosophy; the same Philosophy teacheth vs *That nothing produceth it selfe*. Seeing then that motion produceth Sound, certainly Sound can be no Motion.

It may be obiected that *Aristotle* in the 58. Text of his Booke *de sensu & sensili* and the first Chapter, sayth that Sound is a Motion; but we answere that he speaketh not in a formall sense but in a casuall, that is, not indeuouring to giue the definition of a Sound but a casuall production, as if he should say; when some motion is made with such and such circumstances, a Sound will result therefrom. Obiection. Solution.

VVe will also add another Reason and that very strong which is on this maner. Those things which haue a particular existence or being one without the other, are in themselues seuerally distinct and diuers. Now the sound and the breaking motion of the ayre haue seuerall and particular beings, because the sound is diffused and attaineth to those parts of the Aire or water, to which parts the motion cannot reach. And this *Aristotle* in his fourth Booke *De Historia Animalium* prooueth by the example of Anglers, who in the time of their disport are as silent as may be, and yet the Fishes heare them. Now saith *Aristotle* it is not like that their whisperings can produce so vehement a motion that the partes of the Aire broken thereby should by succession mooue thorough the whole masse of water vnto the Sense of the Fish. Aristotles instance.

Againe, that this fraction of the Aire is not the next and immediat generation of the sound may thus be euicted. Locall motion of it selfe contendeth or striueth onelie vnto *Place*, neither of it selfe doth it make impression of any other reall *Being* vpon that which is mooued, as *Aristotle* teacheth in the eight Booke of his Phyficks the 7 chapter and the 39 Text. It followeth therefore that the generation of Sound is another action besides the motion, which action I know not how to name; yet we may wel conceiue a difference betweene the locall impulsion and the Sound, as we may also perceiue that besides locall motion sometimes heate is engendred, yet no man will say that motion is the immediate cause of heate. That sound is not immediately generated by motion.

After this manner also we may well conceiue how the influences of the Stars may be dispensed in this inferiour world. To conclude therefore it is manifest that there must concurre three actions to the production of any Sound, and these three do each accompany and succeede other. The first action is the affront which is betwixt the two bodies which offend one against another. The second is the fraction or breaking of the *Medium*. The third and last is the *sounding* of the *Medium*, for so you shall giue vs leaue to call it, because wee can deuise no other name. Immediately after this followeth the Sound.

QVEST. XXXIX. *The definition of a Sound.*

HAuing as plainly as wee could deliuered the manner of the generation and production of a Sound we will now briefely set downe the definition of it. *Aristotle* in the 65 Text of his second Booke *de Anima*, defines a sound to bee A motion of that which may bee mooued with that motion wherewith those things are mooued which do rebound from the mutual percussion of two bodies. Others do define it to be A sensatiue quality striking the hearing and the proper obiect of that Sense. But we will thus define it, *A Sound is a passiue and successiue quality produced from the interception and breaking of the Aire or Water which followeth vpon the collision or striking of two sounding bodyes, & so fit to moue the Sense of Hearing.* If any should obiect, that there is but one onely Nature of one thing, as *Arist.* saieth in the 4 chapter of his first Booke of Topickes, and that a definition is an oration expressing the nature of a thing, as the same *Aristotle* in the 5 chapter of his first Booke and the sixt chapter of his 5. Booke of Topicks saith, *There can be but one definition giuen of one and the same thing*, and therefore a Sound should not consist of one simple but of a threefolde Nature, because The definition of a Sound. Obiection.

we

A threefolde definition of Accidents.

we haue set downe three definitions one differing from another, whereas wee promised but one definition in the Title of this Chapter. It is therefore to be considered that three things may be obserued in all Accidents, and from the knowledge of these their Nature may be better manifested: these are the *subiect*, the *genus* and the *Cause*: By which three according to the diuers intention and end of the definer such accidentes are defined either with the mention of them all, or of the subiect and *genus* onely the cause being leste out, or of the cause alone omitting the other two. The first manner of defining satisfies the vnderstanding best, the other affoords but a lame & defectiue vnderstanding of that which is defined.

By the eclips

So in this definition of the Eclipse, that *It is a priuation of the Light in the Moone by reason of the interposition of the Earth betwixt the Moone and the Sunne; all three are contained.* Likewise the Thunder defined to be a *Sound in a Cloud made by the extinction of Fire*, is a definition consisting of all three. But this Thunder is onely defined by the subiect and the *Genus*, if we say, that *Thunder is a Sound in a Cloud*, and by the cause alone when we say It is *an extinction of the fire*. Now if the Nature of Accidents be such, and so great variety be in their definitions, there is no reason but that a sound may be described sometimes one way and sometimes another, to wit, either perfectly or imperfectly.

And thunder.

One absolute definition of one accident.

Againe, what hindreth that one and the same thing may not sometimes bee defined absolutely, sometime relatiuely, the nature of it being as it were changed vnder the same name or appellation, as it happeneth to a sound heere. It remaineth therefore that there is but one definition of one thing, but if there be more, there is but one perfect and absolute, or else they be all imperfect and defectiue.

Againe, one definition is conceiued or written absolutely, another relatiuely. Let it not then seeme strange to any man that one and the same thing according to a diuers acception thereof, is by *Aristotle* diuersly defined; as also in the first Booke *de anima* hee defines *anger* to be an appetite of reuenge, and presently after, that it is a Feruour or boyling of the blood about the heart.

Againe, hee describes a house to bee a couer and shelter to defend vs from the violence of windes and showres, and also hee defines it to be a worke or building made of Clay, stone and wood: euen so heere when he describes a sound to be a percussion of one body against another, it is not *formally* defined but by the efficient cause: so wee say the Eclipse is an interposition of the earth, that is, caused by the interposition of the Earth.

Others defining a Sound say it is a passiue quality striking the Sense of Hearing. But we haue added a third (saith *Placentinus*) which notwithstanding I will not Discourse of so fully as he hath done, because many things will fall into the following Controuersies.

QVEST. XL. *Of the differences of Sounds.*

The diffrence of a Sounde from the Essence.

WEe are to know when we treate of any subiect, first what it is, and then how manifold it is, wherefore hauing set downe the true definition of a Sounde, we will now speake of the differences thereof, which differences beecause they be drawne from diuers Fountaines and Originals, they are therefore as diuers and manifold.

Graue.

First in respect of their essence they are thus distinguished: Some Soundes continue long, others endure but a while. Both of these may be thus subdiuided: the first dooth either by his long continuance much moue the Sense, or else but a little; and this is called a graue, base or an obtuse sound.

Acute.

But that which is of a smal continuance is diuided into that which either in this short continuance doth greatly moue the Sense, or in the same time doth moue it verie little, and this is called an acute or trebble sound, & it is opposite to a graue or base Sound.

Obtuse.

And both these haue borrowed their Names from tactile qualities which do properly challenge these names to themselues. An acute sound hath his name from a sharpe or acute heate or cold; for as these qualities do easily penetrate any body, so this the Sense, which in a short time causeth much Sensation. An obtuse sound hath his name from obtuse or dull heate and cold, because it dooth much resemble them.

And by these may be gathered a manifest difference betwixt a Sound and the obiects of other Senses, for they all doe remaine in the sensible things when the Sensation is past, in which things they actually exist both before and after Sensation, but the Sound dooth va-

vaniſh and goe to nothing, together with the perception thereof. And hence it was that *Ariſtotle* ſayd *ſome ſounding things were onely in* potentia *or in power, and others in Act, &c.*

Againe in reſpect of the Eſſence ſome Sounds are Direct, others Reflected which is called an Eccho. The Eccho.

According to their exiſtence ſome Sounds be in power and poſſibility, others in act. The formall and inheſiue ſubiect of potential Sounds is the Aire and Water, but the ſubiect of an actuall Sound is Iron, Braſſe, Siluer, Gold, Stones, VVood and other hard and ſmooth bodies. And hence doth ariſe another eſpeciall difference betwixt a Sound and the obiects of other Senſes, for theſe doe inhere in the ſenſible thinges actually and ſubiectiuely, both before, in, and after Senſation: but a Sound doth not exiſt in any ſenſible thing actually and ſubiectiuely, neither before nor after, nor yet in the very perception of the ſame. Different ſounds from the eſſence.

Againe, in reſpect of the manner of their production. Some Soundes are made by the fraction of the ayre cauſed by two ſolide bodies, and theſe bodies becauſe they concurre vnto the making of a Sound, being diſtinct either indeed or in ſome reſpect; according to their diuers and manifoulde concurſion this kinde of Sound is againe diſtinguiſhed. Manner of production.

Some are made by alliſion, as when the ayre moued by a vehement winde doth beate againſt a ſolide body, and of this kinde is the ſound when the Lungs doe deliuer ouer the ayre or breath vnto the hard parts of the rough artery which maketh a kinde of wheezing or whiſtling. There ariſeth alſo another kinde of Sound when the ayre beateth againſt other ayre, as it is when the winde is high, for at ſuch time in the open fieldes a man ſhall heare a whiſtling noyſe. The ſound of winde.

There is another kinde of Sound riſing from coition, coition I meane or coniunction of the ayre as when cloath or paper is torne, for then to auoyde vacuity the partes of the ayre do ſodainly conioyne at the ſides of the cloth or paper, where the firſt parts that are driuen are broken by thoſe which follow and ſo make a ſound. Of cloath.

There is another kinde of Sound made by extention of the ayre, as when in hiſsing it is driuen thorough the teeth. Finally, another by conſtriction as in a pipe or a payre of bellowes, or in holes or caues of the earth whereinto the winde driueth the ayre, and when it is in, ſhouldreth it as it were into a corner. Hiſsing.

The differences of Sound in reſpect of the reſonant bodies are double according to the difference of thoſe bodies, to wit, one Naturall the other Violent. I call that Naturall which is made by ſuch bodies as are able from a principle within themſelues to make an impreſsion, or to giue a ſtroke. And this Sound is againe double, the firſt belongeth to animated bodies, the ſecond to thoſe that haue no life. That of animated bodies is a ſound produced willingly by the moouing faculty of the Soule. And it is againe double, that is, made by ſuch organs as are by Narure principally deputed for the production of ſounds, or by ſuch organs as are not to that end appointed. The firſt kinde is yet again double, One formed by the *Glottis* of exſpirated aire and is called a *voyce*, the other is made of aire which is not receyued by Reſpiration, nor formed by the *Glottis*, but by the action of ſom other body. And of this kinde is the ſound of thoſe creatures which we call *Inſecta* and of moſt Fiſhes. The Sound that proceedeth from ſuch organs as are not thereto by Nature deputed is alſo double. Firſt, as when two creatures or two hands do ſtrike one againſt another, the ſecond when one body hath life the other hath none, as when a man ſtrikes his hand vpon a Table. Naturall ſounds. The voice.

Furthermore, the naturall Sound of bodies without life, is that which is made by the action of the firſt qualities, as that of the Fire, of the Aire, of the Water, of the Earth or of theſe mixed: for example, the thundering of Aire when it is concluded or ſhut vp in water and violently breaketh foorth through a narrow outlet. And thus much of Naturall Sounds. I call that Violent which is made by bodies beaten one againſt another by an extrinſecall or outward principle, all which might be nicely parted into ſeuerall Sections if we did not thinke that any man might out of the order we haue before inſiſted vppon frame vnto himſelfe a multitude of diſtinctions or differences of Sounds. Violent ſounds.

QVEST.

QVEST. XLI. *Of the manner of Hearing.*

CONcerning the manner of Hearing the Phyloſophers doe diuerſly diſſent in their opinions.

Diuers opinions of hearing *Alcmæon.*

Alcmæon thought that we doe therefore Heare becauſe our Eares are empty and hollow within, for all empty things doe make a reſonance.

Diogenes.

Diogenes thought that there was a kind of Ayre within the Braine, and that this Ayre was ſtrucken with the voyce, & this conceit was controuerted in *Hippocrates* times, & therefore in his booke περὶ ἀέρων, he inueigheth againſt it; *There are* (ſaith he) *ſome which writing of the Nature of things haue affirmed that the braine doth make a ſound, which cannot be, for the Braine is humide and moyſt, but no moyſt body can cauſe a ſound.* *Plato* writeth that Hearing is made by the pulſation and beating of an internall Ayre.

Hippocrates.

Plato.

But we paſsing by theſe ſlippery wayes of opinions will inſiſt vpon the true manner of Hearing, and in a ſhort and familiar diſcourſe diſplay the whole Nature thereof. For becauſe the Organ of Hearing was vnknowne to the antient Phyloſophers and Phyſitions, particularly to *Ariſtotle* and *Galen* in whoſe dayes Anatomy was but in the infancie and therefore the many ſmall and curious parts of that Organ not found out; we cannot therefore collect the perfect nature of Hearing out of their writings, and therefore in this diſquiſition we muſt truſt more vnto our owne experience.

How hearing is made.

Ariſtotle in his ſecond booke *de anima* and in his booke *de ſenſu & ſenſi.t*, ſaith, that three things are required vnto ſenſe.

The obiect of it.

The obiect, *medium* and inſtrument or Organ, the obiect of the Hearing is Sound, as colour is the obiect of the light, but of the Nature of a ſound, wee haue intreated already as much as is neceſſary for this place. Onely I will call to your remembrance by the way, that a Sound is a quality ariſing from the fraction and breaking of the Ayre which is made by the percuſsion of two hard and ſolide bodyes, for ſoft things doe eaſily yeeld, neither doe they reſiſt the force of that which beates againſt them.

What ſound is

The *medium* of it.

The *medium* or meane of Hearing is the externall Ayre, for *Ariſtotle* doubted whether a voyce could be heard in the water or no, and yet he knows very well that Fiſhes do heare who was euer preſent at the fiſhing for Mullets in the night.

The Organ of it.

The inſtrumtnt of the Hearing is not the externa l Eare, but the internall, which conſiſteth of foure cauities and many other particles vnknowne to the Antients.

The manner of hearing.

The manner therefore of Hearing is thus. The externall Ayre beeing ſtrucken by two hard and ſolid bodyes, and affected with the qualitie of a ſound doth alter that Ayre which adioyneth next vnto it, and this Ayre mooueth the next to that, vntill by this continuation and ſucceſsiue motion it ariue at the Eare. For euen as if you caſt a ſtone into a pond there will circles bubble vp one ouertaking and mooving another: ſo it is in the percuſsion of the Ayre; there are as it were certaine circles generated, vntil by ſucceſsion they attaine vnto the Organ of Hearing. *Auicen* very wittily calleth this continuation of the ſtrucken Ayre *vndam vocalem, a vocall waue.*

But this kind of motion is not made in a moment but in ſucceſsion of Time, whereupon it is that the ſound is not preſently after the ſtroke, heard from afarre. The Ayre endowed with the quality of a ſound is through the auditory paſſage, which outwardly is alwayes open, firſt ſtriken againſt the moſt drie and ſounding membrane, which is therefore called *Tympanum* or the *Drumme*. The membrane being ſtrucken doth mooue the three little bones, and in a moment maketh impreſsion of the character of the ſound. This ſound is preſently receiued of the inbred Ayre, which it carryeth through the windowes of the ſtony ſtone before deſcribed, into the winding burroughs, and ſo into the Labyrinth, after into the Snaile-ſhell, and laſtly into the Auditory Nerue which conueyeth it thence vnto the common Senſe as vnto his Cenſor and Iudge. And this is the true manner of hearing.

QVEST

QVEST. XLII. *Whether the proper and inbred Ayre contayned within the Eare be the primary and principall Instrument of Hearing.*

THE proper and ingenit ayre which the Barbarians call *Implanted*, and *Aristotle inædificated* and *immoueable*, is contayned in the second cauity of the Eares, which the same *Aristotle* calleth the *Snayle-shell*. Some dot call it *Immoueable*, because it is not mooued by any other, but alwayes remaines the same in the Eares. Others call it *immoueable*, because it hath no naturall sound, but can receiue all the differences of Sounds. The auntients thought that this ayre was the chiefe and principall organ of Hearing, and in respect of this ayre *Aristotle* in his second booke *de Anima*, and in his booke *de Sensu et Sensil.* saith, the nature of the Hearing is ayrie. The names of it.

Indeede I esteeme this Ayre to be very necessary vnto Hearing, yea so necessary that Hearing can scarsly bee performed without it: but I can neuer perswade my selfe that it is the principall organ of Hearing. It is an vniuersall Theoreme and generally true, that in euery perfect organ there is some certaine particle to which as to the chiefe cause the Action is to be attributed; so in the Liuer the παρέγχυμα maketh Sanguification. In the Eye the Cristalline humor causeth Sight, in the Muscles, flesh effecteth motion and the Mammillary processes doe make the Smell. But it will be obiected, that this inbred ayre is not a Similar part, therefore no such Action is due to it. The inbred ayre is not the principall organ of Hearing.

Now that it is no part may be thus demonstrated. Euery Similar part is either Spermaticall or fleshie, but this ayre neither deriued his Originall from the seede nor from the blood; therefore it is no part. If it be answered, that it is not indeede a simple ayre but a kinde of spirit. I againe reply, that it cannot be a spirit; for if you conceiue it to be a vitall spirit, it should not forsake the Arteries. If you say it is Animall, then should it follow that an animall spirit should be accounted the chiefe Instrument in the organs of the other Senses. The inbred is no part.

Againe, a spirit is the most commmon organ of the Soule, which that noble forme vseth vnto the performance of all her functions. But as there is a peculiar part in the eye which doth primarily cause vision, to wit, the Cristaline humor; a Similar and Spermaticall part generated of the purest portion of the seede: so there must be such a Similar part found in the Eare. But such is not that ingenit or inbred ayre, because it differeth nothing from the outward ayre, but onely in purity and rest. It is generated of the outward ayre, not indeed by coction and elaboration, as are the spirits; nor yet by any action of the Soule, but by the continuall arriuall of new ayre, which partly is brought thorough the hole of the Eares, being alwayes open and winding, vnto this Cochlea or Snaile-shell; partly deriued thither, by inspiration thorough a certaine little hole or pipe like a *water-course* opening into the palate. How it is generated.

Moreouer, wee may out of *Aristotle* in the second booke *de Anima*, proue that nothing without life can be the instrument of any Sense: but the inbred ayre is without life or soule, because the Soule is not an act of a simple body. Neither hath this inbred ayre any organs of a soule, for why should this ayre which is onely generated by the outward ayre, not concocted by any faculty of the Soule, be rather animated then that ayre which is in the other cauities of the body. But this ayre doth *rest* in the Eare, and not in other cauities; because it is concluded in a straite hole, and by reason of the windings of these darke laborinths cannot easily passe forth. It is not animated.

It is not therefore the organ of Hearing, but rather an internall *Medium*. For as the outward ayre is strucken by the beating of two bodies together, so is this internall strucken by the externall, & that by the interiection of the Tympane, or Drume, of the Chord or String, and of the three little bones. The same ayre being altered, doth carie the bare Character and *species* of the Sound seperated from the matter, to a nerue of the fift conjugation, led a long and dilated in each Eare. And this Nerue is the chiefe organ of Hearing, as the mammillary processes are of the Smell. It is an internall *Medium*.

Now that this internall *Medium* is required in euery Sense, may bee demonstrated by example, for the watery humor is the internall *Medium* of the Sight, the spittle of the Tast, the cuticle or scarfe-skin of the Touch, and the spongie bones of the Smell. In all which the formes are seperated from their matter, and being so seperated are conuayed to The internall meanes of all the Senses.

the principall αἰσθητήριον or Organ: that is the Christalline, for the Sight, the Pulpe of the Tongue for the Tast, the Mamillarie processes for the Smell, the true skin for the Touch, and so the Auditorie nerue for the Hearing.

QVEST. XLIII. *An explication of certaine hard Problemes about the Eares.*

Why Hearing is more delightfull then reading

IT remaineth that wee proceede vnto the dilucidation of some difficult questions concerning the Eares, which knots we will vntye and explane for a conclusion of these controuersies. The first thing propounded is, How it comes to passe that *wee are more recreated with Hearing then with Reading*: For we are wonderfully delighted in the hearing of fables and playes acted vpon a Stage, much more then if wee learned them out of written bookes. *Cardan* as *Scaliger* saith in his 308 *Exercitation*, contents himselfe with this onely reason, because, saith he, those things which are published in bookes are made vulgar and common, and therefore are not so curiously nor with so much delight read ouer; but good Actors are more rare.

Cardanus.

Disproued by *Scaliger.*

Scaliger refuteth this argument, both because good bookes are as rare as good Actors, as also because it is not the part of a humane ingenuous disposition but of a liuid and malicious minde, to esteeme those things most precious or more pleasant which are vnknowne to others.

His Reasons.

Scaliger therefore presenteth many other reasons of this Probleme. First, because we learne those things which we heare with lesse labour then those things which we reade.

Secondly, because a voyce doth more affect vs by reason of his inflexion and insinuation into our Sense, whereas reading is onely a dumbe Actor.

Thirdly, because those things which be heard, take a deeper impression in our minds, which is made by the appulsion or aduall of a reall voyce. But those things which are seene are alwayes intentionally imprinted, & therfore the Act of Seeing is sooner ended and passeth more lightly by the Sense then the Act of Hearing. Wherefore it followes necessarily that things seene do not sticke so fast vnto vs. And this the Apostle insinuateth when he saith, *He beholdeth his face in a glasse and goeth away, and presently forgetteth what manner of one hee was.* Neither is that of the Lyrick Poet any sufficient contradiction of this where he saith:

Segnius irritant animos demissa per aures,
Quam quæ sunt oculis subiecta fidelibus.
The voyce that sinkes in by the eare doth not so soone offend
Or gall the minde; as when the eyes more faithfull message send.

For that is true of those things which we doe onely beleeue by heare-say, which indeed doe not so neerely affect vs as those things we see done before our eyes.

The fourth reason is, because there is a kinde of society in narration and acting, which is very agreeable to the nature of man, but reading is more solitary.

Fiftly, because a certaine shamefastnesse and obseruancie doth cause vs to apply our eares to him that vttereth any thing by voyce, but in reading there is a kinde of remission in the minde and security from any blame of not profiting. Now wee conceiue more pleasure in a diligent and curious acting, then in a negligent and careless.

Sixtly, wee haue opportunity to demaund a reason of some doubts from him which speaketh to vs; and thence we receiue more profit then by bare reading, from which profit a certaine delight doth arise. Againe, because Bookes cannot digresse from their discourse for the better explication of a thing, as those may which teach by their voyce. For in changing of words or mutuall conference, many pleasant passages are brought in by accident, as the Interlocuters list to aduance themselues; as we see in Comedies it is very ordinary. And by these sauces, as it were, of discourse, is the Hearing more sumptuously feasted, but the vniformity of the stile in things written and the continuity of the sentences causeth the Reader to loathe it.

The second question is, why a mans voyce which is sweeter then the sound of a Pipe is yet not iudged sweeter by the Eare if a man imitate the sound of a Pipe with his voyce for when a man sings his voyce is sweeter then a Pipe, but a Pipe is more pleasant then mans voyce when he whistleth.

Some

Some resolue this probleme thus, that it so hapneth because that which is naturall is more pleasant then that which is counterfeited and fained. And therefore when a man singes he addeth an articulation to his voyce aboue the sound of the Pipe; wherefore it is not strange that it is iudged to be sweeter; but when he imitateth a pipe or whistleth, hee doth not so sound pleasantly as a pipe, because he doth counterfeit it.

The third question is why we do conceiue a song to be more pleasant in consort with a pipe then with a harpe. I answer, because both the sounds are heard distinctly by themselues and better mingled together, for both a mans voyce and the sound of a pipe are accomplished by a breath within, but the sound of a harpe is not so. Againe, it may be thus answered, because a pipe, whose sound is somewhat akin to the voyce, doth drowne many faults in the song, which the sound of a harpe doth not being fine & final & vnfit to consort with the voyce but is heard distinctly by it selfe carrying his owne tune simple & pure & so discouers all the slips and errours of the song by his owne inst and proportionable harmony. Now seeing that in singing many things happen out of order that sound which doth most of all bewray the confusion that is betwixt harmony and discord must needs be more harsh in the Eare. 3. Question.

The fourth question shall be, why children when they heare musicke doe first ceasse their crying and after fall asleepe. *Alexander* in the 121. Probleme of the first booke, rendreth this reason of it: because there is a kinde of harmony in the soule by instinct, as other sciences be; neither doe we obtaine any thing by *doctrine* as *Plato* affirmeth, but onely by *recalling to mind*. As often therefore as the soule perceiueth any pleasant melody, she as it were, repeating and calling to mind her owne Nature, causeth the infant to ceasse crying, and luls it asleepe by drawing it selfe from the trouble of outward obiects. 4. Question.

These are the Platonists arguments.

But *Aristotle* more truely resolueth this probleme in the 39. probleme and 19. section where he demandeth *why all men are wont to be delighted with numbers, tunes and all kindes of musique. Is it because euery thing according to Nature is done by number and measure, that so it might tickle and delight our Senses or our minds?* Surely a great argument of the exact and curious disposition of Nature we may finde in our selues, for when we labour, drinke & eate ordinately, that is, according to our proportion (the scantling whereof is most commonly taken by experience) wee doe not onely conserue the naturall disposition and frame of our bodyes, but also increase our strength and perpetuate the vigour both of body and minde: on the contrary, when when we liue dissolutely, that is, inordinately all things succeed and runne headlong into detriment. In like manner the resonance or consonance which we speake of, is, nothing else but an ordinate or propottionable mixtion or temper of contraryes amongst themselues; which contraryes if they keepe quarter and make, as it were, faire warre, there is a kinde of military order or consent in disagreeing. *Aristotle* therefore conceiueth that the consent of words doth therfore refresh, please and delight the Eares, because it is compounded according to certaine lawes deriued or taken from the nature of the thing. Neither is this onely true in the Sense of Hearing, but also in the obiects of the other Senses, for in a picture onely those colours doe delight the Eyes, and in a feast those sapours the Tast, which are tempered after a certaine maner and proportion. *Aristotle* addeth further, that not onely Musicall sounds, such I meane as are made according to art, but those which they call *modi quadratij*, that is, extrauagants, such as wee call the *blacke Sant as* doe oft times delight vs, especially if we be accustomed vnto them. The reason is because custome is another Nature. Wherefore that which is by custome made proportionable is as well musicall as that which is naturally melodious. *Aristotle*. Example in our selues.

A fifth question may be, why he that singeth the *Base* is sooner discouered if he make any iarre then he that singeth the *Treble*: the like happeneth in numbers, for in that which is greater, the error is more euident; but let vs giue the reason. We say therefore, it is because the base sound consumeth more time, and by that meanes is better perceiued by the Eares; but the Treble sound is swift and doth easily and suddainly passe away. 5. Probleme.

A sixth question is, why we doe not heare well when wee yawne. I answer, that in the act of yawning, (which the Latines call Oscitation) wee shake out and disquiet a dull and sluggish winde which lurketh in the cranies and chinkes of the throate, which winde attaining vnto the Eares by those perforations which are made from them into the palate stoppeth, and fulfilleth the Organ of Hearing, and withall causeth a kinde of disturbing noyse which darkeneth the brightnesse or dulleth the edge, or adulterates the puritie 6. Probleme. Why yawning hinders our hearing.

which commeth from without: ſo alſo we ſee, that if two men talke together & at once, they cannot heare one another, at leaſt not diſtinctly, becauſe the Sounde of eithers voice is repelled by the other, and that is the reaſon that he that would liſten & heare diſtinctly holdeth his breath.

Add heereto, that the holes of the Eares are compreſſed when the *mandibles* or iawes are diſtracted or drawne aſunder by oſcitation or yawning. If then the hole of hearing be compreſſed, the aire which carrieth the Sound cannot ſo freely arriue vnto it.

7. Probleme. The ſeauenth queſtion is, why if a man be within a houſe he will ſooner heare a noyſe that is made without: and on the contrary he that is without the houſe ſhall not perceiue a Sound made within the houſe? The Reaſon is thus rendred, He that is without dooth not ſo well perceiue the ſound that is made within the houſe, becauſe the aire breaking foorth is diſſipated or diuided in a greater roomth or more capacious place and ſo the ſound becommeth dull and looſeth his vigour being parted with the aire into ſo manie parts, or ſtretched into ſo wide an extent. Againe on the contrary, he that is within the houſe doth eaſily heare a noiſe that is made without, becauſe the ſound entering into the houſe is contracted, gathered or vnited, and therefore it muſt needes mooue the Senſe more fully. The very ſame reaſon ſeemeth to bee in the acte of Sight, for beeing within doores we ſee better that which is done without, then if we were without doores we ſhold diſcerne what is done within, for the ſpecies comming from without into the houſe are gathered and vnited. Againe, the viſiue vertue of the eye within the houſe which vndertaketh to view that which is without is eaſily diſſipated or diſvnited.

8. Probleme A precis queſtion. *Ariſtotle.* The eight and laſt queſtion ſhall bee, whether when manie men talke together they can be heard further then if one man onely ſpake, imagining the voyces to be equall. This queſtion made *Ariſtotle* at a ſtand, yet hee reſolueth it thus in the ſecond probleme of the 19 Section. It is (ſaith hee) becauſe it is more eaſie to worke with vnited powers then with ſingle and ſeparate, for all compound thinges are of greater force then Singulares. VVherefore when many mens voices go together, the Sound muſt needs be conſtant and vnited, and ſo driue the aire much farther then otherwiſe it would bee driuen by a ſingle Voice in the ſame Key.

Experience. To *Ariſtotle* we adde Experience and Example. Experience, becauſe you may heare the tumult of an Armie further then the vociferation or crie of one Souldiour.

Examples. Againe, in Markets and Fayres where many people are aſſembled, the murmur of the multitude is heard further then the voice of one man though he be lowder then his Fellowes. The noiſe of a Frogge is not great Iwis, yet what time they breede they may bee heard many miles out of the Iſle of *Elie*. Neither are we to wonder at this, for wee haue examples of the like in the obiects of other Senſes, as many Candles of an equall bignes wil enlighten the aire further then one Candle though it be bigger then any of the other. A heap of ſand may be ſeen a great way off on the Seaſhore, but a moat of ſand can ſcarſly be diſcerned vnder the eye. If therefore it be ſo in the viſible obiect, why ſhould we not acknowledge it in the audible? For although the ſpecies of particular voices are not vnited, yet where there is a totall aggregation or heaping vp of many ſpecies together, they may produce one that a may attaine to a further limit then any of them could doe in particular.

Ariſtotle contradicteth himſelfe. I knowe well that *Ariſtotle* in another place, that is to ſay the 52 Probleme of the 11 Section ſeemeth to contradict that we haue before alledged out of him, which was the reaſon that I ſaide before *Ariſtotle* was doubtfull in the reſolution of this queſtion, but becauſe that which we haue quoted is the laſt, and after-thoughts (they ſay) are the Wiſeſt, we will reſt our ſelues therein: for if we ſhould take occaſion to diſpute with *Ariſtotle* too and fro alwayes when we haue occaſion offered, we ſhould wearie our ſelues, and forget that our Philoſophie is not of the maine, but by the Bye. VVherefore wee returne againe to our Anatomie.

QVEST. XLIIII. *Of the wonderfull ſimpathy and Conſent of the Eares, the Palate, the Tongue, and the Throttle.*

The ſimpathy of the Eares & inſtruments of the voice. THere be many things which do manifeſt this wonderfull *συμπνοια* or communion of the eares with the inſtruments of the Voice, which that *Genius* of Nature *Ariſtotle* in the 32. Section of his Problemes hath declared. For when wee would heare any thing attentiuely we hold our breath, when wee yawne we do not

not heare so exquisitely. And if you goade the Tympane of the eare with a Pen-knife it will presently cause a drie Cough. Those which be halfe deafe do speak but stutteringly and their voyce is made through their Nose. Againe, those who from their Birth are deafe, are in like manner ἄφωνοι, that is, are dumbe.

Lastly, if you holde an Instrument in your mouth or betwixt your teeth and stop your eares, you shall heare more perfectly; whence it is that deafe men do heare best by theyr mouths. All these are certaine and plaine arguments of that communion and sympathy which is betwixt the eares and the vocall instruments, to witte, the Mouth, the Tongue, and the Throttle. Whence this cõmunion is.

But the reason of this communion is not knowne to all. Some thinke, that the Auditory nerue, or the Nerue of the fifte Coniugation and that of the seauenth which mooueth the Tongue are couered with the same coate from their beginning, and therfore the affects of those parts are easily communicated. But ocular inspection doth perswade the contrary, for the passages and wayes of either coniugation are diuers, and there is a great distance betweene them. VVe (saith *Laurentius*) will acknowledge a double cause of this communion, the one is referred vnto the auditory Nerue, the other vnto a little Canale or pipe which was vnknowne to the Ancients.

The Nerue of the first Coniugation brancheth out into many surcles, the larger is dilated into the Eare and the Membrane of most exquisite Sense, and carrieth the species or formes of all Sounds vnto the Braine; the lesser runnes vnto the Tongue and the Throttle. The affects therefore of the Eares and the Tongue are easily communicated by reason of the communion of the vessels, which according to *Hippocrates* and *Galen* is the onely cause of this sympathy. Hence it is that the Membrane of the eare being prouoked or goaded doth cause a drie cough, whereof *Auicen* maketh mention. Hence also it is, that almost all deafe men be dumbe, or at least haue but an imperfect speech, the auditorie Nerue being affected, which is complicated or folded with the seuenth coniugation. For I do not approoue of that common position, that deafe men be therefore dumbe because they can learne no Language, and because Hearing is the Sense of knowledge. For if they were onely dumbe for this cause, wherefore should they then sigh & mourne with so great difficultie which are Naturall passions? VVhy should they not; as well as those which were the first inuenters of things, faigne Language and words whereby they might expresse the thoughts and Discourse of their mindes if they could vtter them? For Nature hath armed a Man although hee bee deafe with Reason and Vnderstanding for Inuention. A double cause of this communion. *Hippocrates* his community of vessels.

It remaineth that wee proceede vnto the second cause of this consent which is by a gristly Canale like a water-pipe which is conueighed from the second hole of the Eare vnto the Mouth & Pallate. This course or pipe was appointed for the purging of the in-bred aire, for the auoyding of the excrements of the eares, as also that the in-bred ayre might bee recreated by the arriuall of new aire inspired by the mouth; and lastly, that by this way a passage may bee open for the externall aire rushing forcibly through the hole of the Eares, as it is in the noyse made by Ordinance when wee are neere it. The Ayre therefore doth passe freelie out of the mouth into the Eare, and againe retireth from the Eare into the mouth. VVhence it is, that when wee would heare more attentiuelie wee holde our Breath, least the *Cochlea* or Snaile-shell should bee filled with aboundance of inspired Aire and so the Tympane bee stretched. But such as yawne doe not heare so well, because in this yawning or gaping the Tympane is so stretched and puffed vp, that it cannot receyue outward Sounds. The second cause of the sympathy. Reasons of the former instances.

Lastly, by scratching the Eare wee prouoke Spittle, because by that compressing there is an expression of Excrements into the Cartilagineous or gristlie passage, and so from thence vnto the Tongue. And thus much of the Sense of Hearing, now we come vnto the Smell.

QVEST. XLV. *What Smelling is,*

The deſſiniti- of ſmelling.

THat the Noſe was by Nature made as well for Reſpiration as for the Senſe of Smelling, we haue before declared. But what is the Senſe of Smelling, that we doe vndertake in this place more preciſely to vnfould. *Smelling therfore is the middle Senſe of fiue, which perceiueth the odours of thinges drawne in by the Noſthrils for the vſe and behoofe of the Creature.*

It is a great queſtion (which alſo we haue a little touched before) whether to the action of this Senſe the Inſpiration of aire together with the odour be of abſolute neceſsity; and yet the ſtreame and current of mens opinions as well Philoſophers as Phyſitians run vpon the affirmatiue part. For if we deſire or bee willing to endeuour our ſelues to Smell any thing more curiouſly, we draw the ayre in at our Noſtrilles, and that is the reaſon why we cannot ſmell in the water, becauſe the water that is drawne filleth the paſſages of the Organ. *Placentinus* is of the contrary opinion and alledgeth *Ariſtotle* for his authour in the fift Chapter of his Book *de Senſu & ſenſili* where he ſayth that Nature doth but collaterally vſe Reſpiration in the Attraction of odours, which Reſpiration, ſayth he, ſhe deſtinated primarily to another end.

Whether inſpiration be neceſſary to ſmelling.

If therefore Reſpiration be neceſſary to the Smell, then it followeth that Nature ordayned it primarily for that end. For, ſayth he, this is a rule in Nature, that whatſoeuer in our bodies doeth neceſſarily belong to any function that is primarily appoynted for that function, and doth not ſort vnto it by error, chance or accident.

Seeing therefore the primary and chiefe vſe of Reſpiration is to refreſh and cheriſh the heart and his ſpirites, it followeth that it is not altogether neceſſary for Smelling.

Indeede one and the ſame thing may haue diuers vſes, but the principall and primary vſe is but one, for which onely it is neceſſary and to the reſt accommodated onely ſecondarily or by accident Againe, if an odour of it ſelfe be fit to aſcend vnto his own Organ why ſhould we thinke that Reſpiration ſhould be ſo abſolutely neceſſary? Now an odour is nothing elſe but a *hot and dry exhalation* as we ſhall proue afterwards and exhalation; of their owne Nature doe tend or moue vpward. If then they aſcend naturally, why may it not be that a ſweet and pleaſing breath may riſe into the Noſtrilles and paſſe on vnto the Organ of ſmelling without any attraction of the ayre.

Fits of the mother are holpen by ſmels.

Placentinus addeth another argument which hee calleth Inuincible, taken from thoſe women that are Hyſtericall, that is, haue fits of the *Mother*. For ſuch woemen although they haue no Reſpiration at all, doe yet receiue and perceiue odours, and not onely ſo but are almoſt miraculouſly redeemed or recouered by them: what ſhall wee ſay vnto the wombe it ſelfe, doth it not ſmell? yet no man did euer ſay that the wombe did reſpire, but dayly experience teacheth vs that it taketh ſo great pleaſure in ſweete Smels and is ſo offended with that which is noyſome and abhominable, that it mooueth and applyeth it ſelfe manifeſtly vnto the one and auoydeth the other, euen with Locall and Methematicall motion.

The wombe followes ſweet ſauours.

Obiection.

But it may be obiected that if we hold our breath we cannot ſmell, and therefore this Senſe is not accompliſhed without Inſpiration.

Solution.

Placentinus anſwereth, that it is not true, that if an odour be applyed to the Noſe and the breath retayned, no Senſe will bee made; and thoſe who vrge experience are deceiued in their experimenting. For the breath cannot bee ſo retayned that nothing at all ſhould either get in or out. If then any thing enter in it helpeth the attraction of the odour: if any thing get out it hindreth the ſame, yea it repelleth or driueth it from the Organ. And that the breath cannot be ſo immouably retayned, may be conuinced by reaſon and experience.

Reaſon ſayth, that becauſe ſuch retention of the breath is violent and againſt nature, Nature will likewiſe with all his force and vigour reſiſt and oppoſe that violence, and beſide that all the Organs of Reſpiration doe by a proper inſtinct haſten to their Naturall Action.

Hence it followeth that the Muſcles ſtaggering as it were in their worke of ſuſtentation, and the Lungs declining downeward by their waight, doe betwixt them perpetually expell ſome ſmall quantity of ayre, which is a ſubtle and fluide Element, and wil finde way through inſenſible paſſages. Now that there is ſuch an inſtinct in the muſcles ſeruing to Reſpiration & that this inſtinct may doe much, we may eaſily coniecture, becauſe though a muſcle is otherwiſe an inſtrument of voluntary motion; yet euen in ſleepe when all e-

lection

lection is abſent, and the wil, eſpecially vnto motion, is at reſt as well as the body; yet euen then the intercoſtall muſcles, and the midriffe which ſerue for Reſpiration doe follow the neceſſity of Nature, and mooue as freely as when we are awake. Shall wee therefore conceiue that vpon the ſame neceſſity or a greater, when wee our ſelues doe voluntarily ſeeke to oppoſe and fruſtate the end of Nature, ſhee ſhall not bee able without our knowledge and againſt our wills to let out ſo ſmall a quantity of Ayre as may ſuffice for this her purpoſe; of Ayre I ſay, which is ſo ſubtle & fluid a body that it will iſſue at the leaſt crannie and yeeld vnto the leaſt impulſion or violence?

Experience confirmeth the ſame thing, for if you burne any thing that is odoriferous vnder the Noſe and retaine your breath, you ſhall finde, nay you ſhall ſee, that that fume will be mooued on this ſide and on that ſide, which no doubt commeth to paſſe by reaſon of the Ayre which paſſeth and repaſſeth outward and inward: but if it get within the noſthrils then it is preſently ſmelt as any man that liſt to try may perceiue in himſelfe. Indeed ſome men of no ſmal eſtimation haue affirmed that we cannot ſmell if we retain our breath, but the true reaſon is, becauſe the odour doth not attaine vnto the Organ, nay it doth not enter into the noſthrils, for therein they are deceiued. They thinke they canne hold their breath immooueable, whereas indeede the natural inſtinct driuing their breath foorth, doth alſo driue the odorable obiect from the Organ, but let them proue that though a fume doe of it own accord aſcend into the cauities of the noſthrils, yet it is not perceiued by the Senſe of ſmelling vnleſſe they adde reſpiration thereto, and then I will yeeld them the bucklers.

You will demand, if Reſpiration be not neceſſary why doe we purpoſely draw our breath when we would ſmell. Queſtion.

The anſwer is at hand, to wit, that the obiect may ſooner and more plentifully attaine vnto the Organ. VVe grant therefore that Inſpiration helpeth the Smell m ch, but it doth not thence follow that it is neceſſary. Againe, to the maintenance of life Inſpiration is abſolutely neceſſary, but for *better life*, not ſo, but onely by accident or ſecondarily. In like manner we confeſſe that the Senſe of ſmelling is not ordinarily without Reſpiration but yet it may be; and Reſpiration is not neceſſary to the being, but to the better beeing of the Senſe. And if nature had prepared the way of Reſpiration through ſome other member, and not through the Noſe; yet vndoubtedly the Noſe would haue ſmelt, as we may ſee in thoſe creatures, which do not reſpire. And this is *Placentinus* his opinion. Anſwer. Concluſion.

QVEST. XLVI. *Why Man doth not Smell ſo well as many other Creatures.*

PLato in *Timæo*, and *Theophraſtus* in the fixth chapter of his ſixth book *de cauſis plantarum* together with many other who haue written of this ſubiect, all of them, I ſay, with one conſent doe acknowledge that the Senſe of Smelling is more dull in men then in many other Creatures.

The ſame doth *Ariſtotle* auouch in the fourth chapter of his booke *de ſenſu & ſenſili*, where hee alſo addeth that of all the ſenſes this Senſe of Smelling in man is moſt ſluggiſh and dull, which alſo he confirmeth in the 92. text of his 2. book *de Anima*. What creatures ſmell better then men.

The truth of this opinion is very euident by the example of other creatures as Dogges, Hogs, Crowes, Bees and other birds and beaſts which are able a farre off to *wind*, as wee ſay, the ſent of any thing. But man is conſtrayned to moue the obiect euen vnto the Noſe and yet he is not able to diſcerne or perceiue any ſmels but thoſe, that are ſo ſtrong that they alter the Senſe either into pleaſure or paine. Add hereto, that many brute beaſtes doe know more by their ſmels then man can attaine to by all his ſenſes, as the Hound that hunts vpon the cold foote of a Hare or a Deare, yea they can in the night follow a mans ſteps and worke out his way through a thouſand difficulties and intanglements or permixtion of other Smels. So we ſee alſo that in the darke a Dogge will know his owne maſter from a great many other men onely by his ſmell. A Tyger being robbed of her whelps will finde them out againe by her ſm ll. Now none of theſe odours can the Senſe of ſmelling in man apprehend. Beaſts ſmell many things that men can not.

The reaſon hereof, *Ariſtotle* in the place before quoted referreth vnto the fault, not of the faculty, but of the Organ. For this Organ is cold and very moyſt, but the obiect hot and dry: now it is neceſſary that the Organ ſhould potentially b e ſuch as the ſubiect is actually. So that when ſenſation is made the obiect may worke vpon the inſtrument and con- The reaſon of it.

uert

uert it into his Nature. But in this Sense of Smelling such conuersion cannot be made without great difficulty, for that which is moyst doth hardly become dry, and by reason of this difficulty a man smelleth but remisly or dully, that is, not without either pleasure or paine. The reason is, because the Obiect must be very vehement before it can turne the moysture of the Organ into his owne Nature, that is, make it hot and dry.

Other reasons.

Beside, this proper & natiue vnfitnesse of the Organ, there is also another ineptitude added, and that is the vicinity or neighbourhoode of the braine, which is in man much greater in respect of his magnitude then in other creatures. Seeing therefore the braine aboundeth with moisture, which moisture is also imparted vnto the Instrument of Smelling; it commeth to passe that that Instrument by this coniunction of the braine becommeth more vnapt. Whence it is that the same *Aristotle* in the 33. Probleme of the tenth Section, hath obserued that the Instrument of Smelling is much incommodated by the moyst superfluities of the braine. The power therefore of Smelling being as it were steeped in this moisture groweth dull and sleepy, which in that which is hote and dry would bee awaked and shew it selfe; and therefore in bruite beasts whose braines are not either so moist, or at least yield not so much moisture because they are lesse, this Faculty or Sense is more pregnant and apprehensiue.

Obiection.

Some arguments are neuertheless made to the contrary, for thus they say: Where the forme is more excellent, there also the faculty is proportionably excellent. Now wee know that the forme of a man which is his Reasonable soule, is farre more excellent then the Sensatiue forme of a bruite beast, wherefore the faculties also of his forme are more perfect, and among the rest that of Smelling.

Solution.

We answere, that albeit the Soule of a man is much more excellent and diuine then the Soule of a beast, yet so long as it is chained in the prison of this body of Earth, it cannot performe his functions but by the helpe of corporeall Organs, and therefore as the Temperature and conformation of the Organs is more or lesse conuenient, so are the functions more perfect or imperfect. Seeing therefore that the Organ of Smelling by which as by a hand the Soule reacheth odours vnto it selfe, is as we said in men somewhat to moyst, and therefore vnfit for the sodaine and quicke reception of odours: it followeth that by reason of this fault of the Instrument the faculty of the Soule is as it were abated or allayed that it cannot so perfectly and freely manifest it selfe.

Obiection.

It may be obiected againe, that because the Organ of a mans Smell is colde & moyst, hee should Smell the better not more dully, for that which is hote and dry as odours are, doth worke more powerfully vpon that which is the coldest and the moystest.

Solution.

True it is, that the odour will worke better vpon the Organ, but as I said before, cannot so easily conuert it into his owne Nature, for the qualities of the Organ are in a great degree contrary & repugnāt to the nature of the Obiect, but when sensation is made they must grow to be alike. Wherefore if the Organ be so disposed that there is not so great a difference betwixt it & the nature of his obiect, it cōmeth to passe that they consent better together, and the Organ yeeldeth more easily toward the Nature of that which doth importune it: But we proceede vnto the Nature of an Odour.

QVEST. XLVII. *Of the Essence of an Odour.*

Heraclitus opinion of Odours.

Refuted by *Aristotle.*

HEraclitus, as *Aristotle* remembreth in the fift Chapter of his Booke *de Sensu et Sensili*, conceiuing that Odours are a fumide exhalation, sayeth, that if all *Beings* had beene fumide the Nose would haue discerned of all. *Aristotle* replies vpon him on this manner. If that were true which *Heraclitus* collecteth, it would follow that those creatures which liue in the water do not Smell, for in the water there can be no fumide or smoaky exhalation generated. But that Fishes doe smell may bee proued by the choise of their meate, which *Aristotle* perswades himselfe they make by Smelling.

We, saith *Placentinus*, haue other Reasons against this opinion: First, because a fumide exhalation is a substance, for it subsisteth by it selfe and sustaineth accidents, and therefore naturally and by his owne motion we perceiue that it mounteth vpward. Now then if an Odour were a fumide exhalation, it could not be by it selfe sensible, for no substance doth by it selfe fall vnder any Sense. Yet no man will denie but that an Odour doth by it selfe and immediately worke vpon the Organ of Smelling.

Placentinus refutation of *Heraclitus.*

It is true indeede that a fumide exhalation attayning to the nosethrils mooues the Sense of Smelling, but it doth not follow that therefore such an exhalation is an odour: rather wee should say that the Odour hath his subsistence in the exhalation as in her subiect,

ject: for accidents neither are, nor can be without their subiects.

Notwithstanding there is a place in *Galen* neare the end of the second chapter of his booke *de odoratus organo* which seemeth to prooue this opinion of *Heraclitus* to bee true; the words are these; *That falleth into the Sense of smelling which is betwixt the Nature of ayre and water, to wit, such a thing as is neither so thin as ayre nor so thicke as water, for that which exhaleth or vapoureth from the bodies of things is the substance of odours, which wee may perceiue by roses and the like tender plants whose bodyes doe quickely become lesse crumple, and dry vpwhence we may certainely gather that the more humide part of their substance is resolued in to exhalation.* Thus farre *Galen.* A place of *Galen* expounded.

Andanswered We answer that *Galen* saith that the substance of an odour is an exhalation, by substance there meaning the subiect wherein the odour doth consist, for it had beene a grosse thing in *Galen*, and vnworthy the edge of so keene a Phylosopher, if hee had attributed substance to an odour which hath no existence of it selfe.

And if any man shall insist vpon the example of Roses, we will giue him this satisfaction, that *Galen* doth not conclude that Roses therefore doe become lesser and dryer, because their moystest parts are exhaled into odours, but he saith that their moyster part turneth into an exhalation: and he saith true. for an exhalation which is a substance absumeth the humiditie of the body out of which it issueth, and diminisheth the same; for how can it be but diminished when a substantiall part is taken from the whole. But an odour is not a substantial part, neither is it made of a part, but subsisteth in the whole subiect, and is nothing else but *an accident or an incorporeall qualitie.* So that out of these words of *Galen* wee may gather this excellent point of learning. That where he saith, *That which exhaleth from the bodyes of things is the substance of an odour*, hee doth wisely signifie the *matter* out of which the odour doth arise which is the body, and the *subiect* wherein it doth inhere which is the exhalation; whereas therefore he saith that the exhalation is the substance of the odour, he doth not meane that the odour is a substance, but being an accident that it doth subsist in this substane as in his subiect.

But for the confirmation of this opinion of *Heraclitus* there are some obiections made to prooue that the odour it selfe is a fumide substance, because it performeth many things which cannot be done, but onely by a substance. And first, a creature may thereby bee nourished, for which they alledge *Plinie* in the 2. chapter of his seuenth booke where hee saith, that in the Easterne India about the fountaine or head of the River Ganges, there is a nation without mouths, whom he calleth *Astomy* hairie; all ouer ther bodyes and cloathed with the leaues of trees. They liue of nothing but exhalations and odours which they draw in through their Noses; meate they haue none nor drinke: onely they vse to smell vpon certaine roots and flowers and wilde Apples which they carry with them when they trauell farre, that they might not want something to smell to. These men are easily stifled with a strong odour. A story out of *Plinie.* The Astomy.

The like we reade of *Democritus* who they say sustained his life foure dayes with the smell of honey or hot bread. VVe answer with *Aristotle* in the fifth chapter of his book *de sensu & sensili*, where he ascribeth this opinion to the *Pythagorians* that such strange reports are meere fables vnworthy the credite of a hystory, because they abhor so much from reason. For those things which do nourish must be conuerted into the substance of the liuing body. Now that which is incorporeall cannot possible be conuerted into a corporeall substance; wherefore odour being of it selfe an incorporeall accident and therefore not changed into the substance of the creature cānot become a nouriſtment therto. Beside all creatures haue some place in their bellies which receiueth their meate, and from whence the body draweth that which sustaineth it. But the Organ of odours is seated in the head from whence no member of the creature seeketh for nourishment. *Democritus.* Reasons against *Plinie.*

They vrge further the example Cookes, who because they are busie in boyling and roasting viands for other men, doe receiue so many odours from them that they scarse euer are a hungry or desire meate, but rather being satisfied with the smell doe loath the substance, and therefore it is commonly thought that these smels doe satisfie and cloy thē. But we deny that this commeth to passe by reason of the odours of meates, but the reason why they desire not meate as other men, is, either because as it is in the prouerbe, they can licke their owne fingers, that is, tasting a little of euery thing they insensibly fill their stomackes, or being alwayes about the fire their pores are opened and the inward heate dissipated which is wont to mooue and solicite the appetite, which also is the reason why euery Why Cookes haue no good stomackes.

ry man in winter eats more then he doth in Summer; Or we may say, that they are dried by the heate of the Fire and so become thirsty and drinke often, insomuch that the stomacke being relaxed or loosened by the moysture of drinke becomes languide and so the appetite is broken: or we may say further, that being very dry they cannot be hungry, because *Aristotle* sayeth it is impossible that at one and the same time a man shoulde vehemently desire both meat and drinke.

Obiection. It is further obiected that as *Aristotle* sayth in the fift Chaptet of his Booke *de Sens. & Sensi*, which also is prooued true by experience, that when we are full wee loath the Smell of meates, but delight in the smells of Spices and Roses. If therefore the odour of meate did not nourish, a full stomacke would no more abhorre the odours of meate then of Roses or Spices.

Solution. But we answere that this saciety hapneth not because of the odours, but because of the steame or exhalation wherein the odour is; for wee grant that such a steame may in some sort nourish: but the odour of Roses which hath for his subiect a more subtle exhalation is better pleasing vnto vs, especially because their smell is very fragrant and acceptable, whereas the Smell of meates is neuer pleasing but when wee are an hungry. VVee conclude therefore with *Aristotle* in the place before quoted. That odours doe not at all nourish. Others disputing more probably doe make according to *Galen* two kindes of nourishments; one which is taken by the mouth and nourisheth the solide partes of the body; another which is drawne through the Nosthrils which nourisheth the thin & ayry parts, as the spirites, for *Galen* affirmeth that the spirites doe feede vppon ayre and odors.

Some say that odours nourish the spirits

Their reasons. VVherefore the nourishment of the spirits they attribute vnto odours, and the rather are they induced so to think because nasty and abhominable smelles doe make men oftentimes swound, yea and such exhalations arising from dead Carkasses or muddy fens doe infect the ayre and breede a pestilence. Adde hereto that in the Low Countries the odour that ariseth from the flowers of beanes as they grow in the fieldes, doe often driue trauellers into a deliration or light madnesses as *Leuinus Lemnius* hath obserued. And *Plutarch* sayeth that by the smell of oyntments Cats doe grow mad. Moreouer, Physitians doe consent that the smell of spices doeth breede καρηβαρίαν, that is, a payne or dull stupidity and fulnesse in the head.

Answere. Adde hereto that many odours or smels are able to refresh a man when he is ready to swound or faint away; they exhilerate or cheare the heart, and if we may beleeue *Aristotle* in the place before quoted, they correct the distemper of the brayne. All these thinges we confesse are true if they be vnderstoode of that vaporous or aerie exhalation or substance wherein the odour is transported, for by that meanes or in that respect onely the odour is sayde to nourish the spirites, and *Galen* in his 8. Booke *de compositione medicamentorum secundum locos* and the 4. chapter writeth, that if with the odours there are also many vapours associated, then, sayth he, such odours haue some faculty to nourish. But if we vnderstand by odours the simple obiect of the smell, naked and separated from exhalations it is vtterly false that they say; for although that vaporous substance wherein the odor is conuayed doe by the helpe of other qualities concommitating or accompanying the odours cherish and refresh the spirites and performe those other good offices which wee haue remembred, yet it followeth not from hence that an odour is a substance; rather that it is an accident of a substance, because it doth inhere in the forenamed qualified vapour. But we will come vnto the definition of an odour.

QVEST. XLVIII. *The definition of an Odour.*

What an odour is. *AN Odour is a quality moouing the smell arising out of a fit mixtion of the foure Elements wherein heate and moysture haue the predominance.* For wee conceiue with *Aristotle* in the fift Chapter of his Booke *de sensu & sensili*, that in the pure and sincere Elements there is no odour at all. *Aristotle* in the beginning of the chapter rendreth the reason, because they can haue no Tast vnlesse they be mingled: for the Taste and the Smell; that is, the sapour and the sauour or odour doe arise out of the same matter; yet so that in sapours there is more moysture, in odours more siccity: notwithstanding in odors the siccity is not at any time without some humour, for those things that wither and are torrified do loose their odours, as may appeare in the ashes of Iuniper, for as soone as all the humour is consumed, the odour or smell vanisheth also therewithall. Againe, some that are ouer-dryed recouer their smels by the permixtion of moysture.

But

But that in odoriferous things the ſiccity is predominant, may be prooued, becauſe ſuch ſweete ſmelling flowres or what elſe you ſhall name, become without ſmel if they be too much moiſtened: hence it is, that *Roſes* gathered in the raine do ſmell verie litle, nothing at all in compariſon of the fragrancie of thoſe that are gathered in faire and dry weather. That alſo is the reaſon why in Egypt the flowers are not ſweete becauſe the aire is moyſt and cloudy by reaſon of the waters of *Nylus*. On the contrary the hot Climats of the Eaſt as *Arabia*, *Syria* & the *Indies* do bring forth Spices and other plants of excellent and delicate Smels. It may be obiected ther are many waters which are verie odoriferous, now no man will denie but that in water the moiſture exceeds the drought. VVee anſwere that in water the odour is onely potentiall and that the heate eleuateth or raiſeth vp from out of them a vapour or exhalation wherein the ſiccity preuailes ouer the humidity, and in this vapour is there an Actuall odour. The Reaſon is, becauſe this mooueth the Senſe, but the other odour which is in the water cannot mooue the ſenſe vnleſſe it exhale together with the vapour and attaine vnto the organ.

That drought is predominat in odours

Why in Egipt the Flowers do not ſmell.

Obiection.

Solution.

The truth of this we may eaſily admit if we draw into our Noſethrils a little ſweete water, for ſo we ſhall not ſmell the odour thereof, becauſe of neceſsity a vapour is required to actuate the odour.

Moreouer, that all that odour is potentiall which conſiſteth not in a vapor but lurketh as yet in mixt bodies, may be conuinced by inuincible argument. For *Ariſtotle* in the 5 chapter of his Booke *de ſenſu et ſenſili* ſaith, the ſubiect of Sapors and ſauours is one and the ſame. If therefore in odours or ſauours ſiccity be predominant, in Sapors or Taſts humidity, it would follow that two contraries ſhould bee predominant in one and the ſame ſubiect, then which what can be more abſurd?

VVe muſt ſay therefore, that theſe qualities are in mixte bodies not actually but potentially, and that they ariſe out of the mixture as out of their matter: ſo that when wee ſay that ſiccity hath the predominance in odours we ſpeake of that odour which exhaleth into acte out of the mixed bodies, and ſo there ſhall be no contrarietie in that we affirme: neither let any man thinke it abſurd, that we ſay two contraries may be potentially in the ſame ſubiect, for water that is tepide or warme, that is, in a middle temper betwixt colde and hot is potentially both colde and hot at one and the ſame time, for it hath an equall diſpoſition to them both, and the reaſon is, becauſe Potentiall contrarietie breedeth no ſtrife in a Real ſubiect.

Potentiall Odor what it is.

QVEST. XLIX. *Of the Cauſes of Odours.*

ALthough the Nature of an odour doth conſiſt in ſiccity, yet it cannot be at any time without humidity, yea it is generated out of humidity, eleuated or raiſed vp into vapours by heate, ſo that there can bee no odour vnleſſe the force and efficacie of heate do boile, raiſe vp and attenuate the humiditie. And this all Herbaliſts acknowledge for a rule, (to wit) that all thinges that Smell ſtrongly are hot, ſo that from the vehemencie or remiſneſſe of the odour they do in Hearbs diſtinguiſh the degrees of heate. So ſaith *Ariſtotle* in the 12 probleme of the 12 Section, ſtrong and ranke-ſmelling ſeedes are hotte becauſe the odour proceedeth from Heate. The like alſo *Galen* affirmeth in the 22. chapter of his fourth Booke *de Simplicium Medicamẽtorum facultatibus*.

Heate is the efficient cauſe of Odours.

A Rule for Herbaliſtes. *Galen.*

Experience alſo manifeſteth the ſame, for perfumes are more fragrant when they are Hot then when they are Colde, and in hotter ſeaſons yeelde a ſweeter ſmel; which is an Argument that the moiſture is better boiled away, and that there is greater plentie of Odour raiſed vp in the aboundance of exhalations which cannot bee looſened and freed from the bonds of the matter wherein they are vnleſſe it be by heate, for cold doth binde and ſhut them vp, neither ſuffering them to yſſue out of their ſubſtances, nor giuing them way to attaine vnto the organ of ſenſe. And after this manner *Plutarch* in the 25 Chapter of his Booke *de Cauſis Naturalibus* aſſoyleth the queſtion, why in a froſtie morning Hounds cannot hunt ſo truly as in open weather.

Sweet things ſmell moſt when they are hotteſt.

Why Hounds cannot hunt in froſt.

But it will be obiected, if the odour bee not a fumide exhalation what neede hath it of moiſture and heate which are the cauſes thereof? VVe muſt remember that whereof wee were admoniſhed beſo e, That Odours in mixt bodies are onely potentially & cannot be produced into an acte vnleſſe they yſſue out of them: wherefore being an accident it cannot yſſue out of his ſubiect wherein it was potentially, vnleſſe ſome other ſubiect doe accom-

Obiection.

Solution

accompany it: for ſaith the Philoſopher the *Being* of an accident is to *bee in*. For out of their ſubiect they are nothing. This ſubiect therefore which produceth the odours into acte is an exhalation. An exhalation cannot be raiſed but by heate out of moyſture. It followeth therefore that both heate and moiſture are neceſſarie in the production of odors. Neceſſary, I ſay not *per ſe* as they are odours but *per accidens*, becauſe they cannot actually exiſt without an exhalation.

Obiection. They vrge further, if an odour be *of* and *by* it ſelfe nothing, then there can be no knowledge thereof, for there is no knowledge of that which is *Non ens* or without being. Againe, a ſubſtance *per ſe* or by it ſelfe cannot be knowne, and therefore (ſay they) we take away euen out of the vniuerſall Nature all Science, for whatſoeuer is, is either a ſubſtance or an accident, third thing there is none.

Solution Indeede we grant, that of an odour conſidered by it ſelfe and ſeparatedly there is no knowledge, for ſo conſidered it is nothing, neither doth it fall vnder Senſe, but as it is ioyned with the exhalation it mooueth the Senſe and alſo falleth vnder Science or knowledge. In like manner Accidents ſeparated from their ſubſtances, and ſubſtances ſeparated from the Accidents doe not fall vnder Science but each by other is mutually knowne and demonſtrated.

No knowledg of an accident without the ſubſtance

QVEST. L. *Concluding that Fiſhes do not Smell.*

An obiection of the *Peripateticks*. SOme *Peripatetian* (ſaith *Placentinus*) may obiect on this manner. If an Odour haue Actuall exiſtence onely in exhalation, ſo that without it it cannot mooue the ſenſe, then what ſhall wee ſay to Fiſhes which liue in the water where there are no exhalations to be found? For *Ariſtotle* in the beginning of the fift chapter of his Booke *de Senſu & ſenſili* ſaith, that there can be no fumid exhalation made in water. The reaſon is, becauſe as ſoone as ayre is engendred in water it riſeth vp out of it in a bubble.

Water conſiſteth of foure Elements. VVe may anſwere, that the Fiſhes do not liue in the pure and neate element of water, but in a water compounded of foure Elements: being therefore compounded there is ſome fire in it, Fire alwayes woorketh, that worke conſumeth moyſture, and ſuch conſumption is abſolued by exhalation or eleuation into vapors.

Seeing therefore, that in water there may be found ſuch euaporation, it may be haply imagined that by it the Fiſhes do apprehend Odours.

But (ſaith my Author) it may be this thredde is too hard twiſted, or too finely ſpun, becauſe firſt wee muſt acknowledge that the Fiſhes ſmell is wonderfull dull becauſe of the predominance of moyſture and colde in the VVater. Againe, I doubt it is ridiculous to ioyne Fire and water, two contraries in the ſame ſubiect, which is againſt the law of contrariety.

And ſurely this blame we ſhould worthily deſerue if we ſhould make the Fire & water equall in their degrees. But wee giue the preheminence vnto the water, and ſay that the Fire as alſo the other Elements do put their qualities vnder his girdle. I doe not ſay that the qualities of the Fire are extinguiſhed or quenched out by the water, but they are remitted or abated, for fire worketh perpetually whereſoeuer it is, and raiſeth vapours although they be neuer ſo ſmall, for this action neceſſarily followeth the eſſentiall forme of Fire, ſo that if you ſeparate it from the Fire, you take away his whole ſubſtance.

The fire is remitted not loſt in the water.

Obiection. Some Philoſophers are of opinion, that the foure Elements are onely potentiallie in compound bodyes, and therefore haue onely potentiall vertues, ſo that Fire which is onely potentially in water cannot actually worke vpon it. But wee Anſwere, that if the VVater being actually compounded of foure Elements, thoſe Elements muſt neceſſarilie bee in it Actually, for that vvhich is potentially cannot make an Actuall Beeing or Exiſtence.

Solution. But we will ſay, if the water be mixed with fire, why doth not the fire warme it? Surely it doth warme it although it bee not able to remoone all the coldneſſe of the water that it ſhould appeare warme vnto the Touch: for if the water were pure and ſincere, it is certain that it would bee much more cold then our water is.

Why Well-water is warm in Winter. And this may beeproued by well water which is ſomewhat deepe within the Earth, for they are hotter in winter then they are in Summer; the reaſon is, becauſe in winter the ſurface of the earth is condenſed or cloſed vp ſo that the internall and elementary heate is preſerued within the earth, which in Sommer when the face of the earth is looſned and relaxed iſſueth into the Ayre. Hence alſo it is that water after it is once heated ouer the fire,

fire, would sooner freeze then other which is newly taken out of a Riuer, because in boyling ouer the fire the inbred heat of the water vanisheth because the parts are relaxed or disunited, but in fresh spring water the natiue heat remaineth which preserueth it from freezing. Now these things could not be thus, except that fire were actually in the water, and did also actually heate it; notwithstanding the Phylosophers may in some sort be held excused, because the pure elements distinguished seuerally one from another are in compoūd bodies potētially, for actually pure elements are not in them. But you will say, that because of the fire which is naturally mixed with the water, there is in the water some litle odour, and that litle odor Fishes do perceiue. But this canot be, for man cannot smell in the water, if fishes therefore could, it would follow that the Sense of Smelling was more perfect in Fishes then in men which is vtterly false. Neither is it any answer to say that the water hath odors therein: or is odorated in respect of of the Siccity, because this S ccity is only potential and vnlesse the humidity which is actually and predominant there be consumed it shall neuer be able to moone the Sense, for actuall odour requireth an actuall Siccity, and that actually predominant. But some man may obiect that the fire which is in the water, rayseth vp exhalations and so odours. The Phylosophers excused

I grant indeede that in water exhalations may be generated: but none such as *Aristotle* vnderstandeth, that is odoriferous, because those exhalations are meerely vaporous wherein the Siccity is yet actually ouercome by the humiditie. But humide exhalations which are the subiects of actuall odours are neuer found in water, which also *Aristotle* confesseth. Notwithstanding the same *Aristotle* prooueth that fishes doe smell, because they make choyce of their meat, as if he should say, that they choose their meate by their Smels, The difference betwixt moyst and dry exhalations.

But to returne to that wherefrom wee are digressed, and at length to determine this controuersie, wee say, that Fishes may so far foorth Smell as the water wherein they liue doth communicate with the Ayre and Fire: for seeing nothing can either bee generated or nourished by a simple element, it must needes follow that Fishes being ingendered and nourished in the water, that water partaketh of the vigour and substance of the rest of the Elements. And this is also manifested by the reciprocall transmutation or change of one Element into another. for no man will deny but that rarified water turneth into Ayre, and Ayre rarified into Fire, which could not possibly bee if the water were pure and vnmixed, for it cannot be imagined how it should receiue or put on, a diuers, yea a contrary nature therewith it hath no affinity or familiaritie. Fishes cannot smell in pure water.

But if any man shall persist and say that the Sea which is the habitation of Fishes, is the pure and sincere Element of water, free from the commixtion of other Elements, then I say, saith *Placentinus*, that Fishes cannot Smell at all. My reasons are, first, because no Sense is mooued but by obiects, but in water which is not adulterated with mixture of any *heterogeny* body cannot produce an obiect of smelling, for odours are in that which is dry, now what is more moyst and freer from Siccity, then pure and simple water. Againe. if odoriferous things by too plentifull effusion of moysture doe loose their odour, how can pure and siucere water haue any odour therein. If therefore Fishes doe smell as *Aristotle* and other classicke authours doe testifie, it must needes bee in reguard of the Siccity which commeth from the permixtion of Ayre and Fre.

If any man shall obiect that water hath no smell in it, because a man cannot perceiue the odour thereof, though hee snuffe it into his Nose, hauing notwithstanding a greater perfection of this Sense the Fishes haue. I answer, that Fishes and those creatures that liue in the water doe smell without respiration or breathing, and without those many helpes of the Organ which are in men. Fishes smell without respiration.

Moreouer, the water being to Fishes a familiar Element, a little odour mixed therewith may moone and stirre vp their senses, whereas in men there must bee a hot steame raysed from that which is odoriferous, there must be also Respiration through the Nose to conuay the same steame through the spongie bone vnto the mammillary processes before this Sense in them can be mooued.

But whereas *Aristotle* absolutely concludeth that Fishes doe smell, because they make choyce of their meate, that consequence we cannot so well approue, for the choyce or election of their meat may proceede from another cause. When wee are to buy any victuals which we may not Taste, wee make choyce by our eyes, beleeuing that that which is best coloured is also best tasted; why should we not therefore think that Fishes may make choyce of their meat by their sight.

Againe, all creatures by an instinct of Nature doe desire and seeke after that Aliment

How Fishes choose their meat by their sight.

By instinct as the infant.

which is proportionable vnto them, for what teacheth the Infant in the wombe to drawe vnto it the mothers blood rather then the rest of her humors. Is it the smell of blood? Nothing lesse, for the Infant doeth not smell at all; yea it draweth the nourishment into the Liuer through the vmbilicall veine by a naturall instinct. After the child is borne what maketh it to choose the mothers milke before all other nourishment. Is it the odour or smell of the milke? No, for we see that when an Infant is layde to the breast, hee suddenly with a kinde of Naturall force laps his tongue about the head of the breast and suckes very strongly. Shall we attribute this work of the Infant to the Smell rather then to an instinct of Nature? By no meanes, for if you deceiue a childe with a suckling bottle or any such thing like the nipple of the mothers breast, as soone as euer hee tastes that which is therein to differ from the Aliment which he naturally desireth he will presently cry and not be appeased till he haue his mothers breast againe. And thus much shall be sufficient to haue spoken of the causes of odours and some difficulties coincident with them. Now wee proceed to the differences.

QVEST. LI. *Of the differences of Odours.*

Differences of odours very nice.

TO distinguish the particular kinds and differences of Odours, & to giue their proper names is altogether impossible, partly because the Sense is but dull, and partly because of our owne ignorance, which the best Philosophers haue not beene ashamed to confesse.

Wherefore those that haue written of this part of Philosophy considering how imperfect our Sense is, to make fitte distinctions of this obiect; seeing wee can smell nothing but that which doeth vehemently goade and affect the Sense: they haue thought good to distinguish the kindes of odours improperly and by way of translation by the differences of Sapours and Tastes: neither haue they done this without good ground; for between Sapours and Sauors, as in the name, so in the nature there is a great affinity, analogy and proportion, insomuch that the odour or sauour dependeth vpon the sapour or Taste. So sayth *Aristotle* in the fift chapter of his Booke *de sensu & sensili*, there is no bode odoriferous which hath not also a strong taste, defining that to be odoriferous or able to moue the sense of smelling, which hath in it power to diffuse a sapide siccity, & a while after he sayth, *If therefore any man shall esteeme both (to wit, ayre and water) moyst, it woulde followe that odour will bee nothing else but the Nature of sapide siccity residing in moysture.*

Therefore referred to taste.

The kinds of odours.

The kinds therefore of Odours which fall vnder our Sense are these. Biting, Sweete, Sowre, Tart and Fat. As for rotten smelles, these sayth *Aristotle* in the place before quoted, are proportionable with bitter Tasts, because as bitter things are hardly swallowed, so rotten or stinking smels are not receiued into the Sense without a kind of regret and loathing. There are two other differences of odours: the first is common to bruite beasts and by accident doeth mooue pleasure or paine, as those odours which together with the steame do arise from meat, which are pleasant to those that are hungry, and vnpleasant and offensiue to such as are satisfied.

The other kinde is of it selfe pleasant or vnpleasant, as the smell that breatheth from flowers, and this is proper to men alone, for they doe not prouoke the appetite more or lesse, but rather by another kinde of satisfaction doe dull and appease it. Yet wee must not beleeue that all the differences of Tastes may be applyed to odours, for who euer said that he felt a salt smell.

Finally, Odours are either Naturall or Artificiall; Naturall odours are those which are naturally in the bodies; Artificiall are such as Apothecaries vse to make for pleasure or for Physicke of the commixtion of many spices, and these we call compound odours, the other simple.

QVEST. LII. *Of the Medium or Meane of Smelling.*

The Philosophers opinions.

IT hath not yet been called into question whether the smell standeth in need of a *Medium* or no. All men taking it for granted, that a *Medium* is required, partly subscribing to that Axiome so often before itterated by vs. That *the obiect immediatly touching the Instrument maketh no Sensation*; partly because in the 97. Text of his second booke *de anima*, *Aristotle* speaking particularly of the Smell, hath assigned thereto a determinate *Medium* or Meane, for in that place hee doth

doth not onely take away the doubt whether this Senſe be made by a *Medium*, but withall he declareth by what *Medium* it is abſolued and perfected. With him therefore as there is great reaſon we alſo conſent. For Odour hauing his reſidence in a fumide exhalation, with which exhalation the Odour exhaleth out of the bodies: that vapour cannot accompany the Odour vnto the Organ, eſpecially where the diſtance is any thing great betwixt the body, out of which the odour iſſueth, and the organ of Senſe, but it muſt be diſsipated vnleſſe it were preſerued by ſome *Medium*, yet euen that *Medium* doth not ſo preſerue it, but by degrees it is diſsipated and vaniſheth away. Wee conclude therefore that the Senſe of Smelling ſtandeth in neede of a *Medium*. But what this *Medium* ſhould be, that ſaith *Placentinus*, I am not reſolued of although I am not ignorant, that all Philoſophers with one conſent doe agree herein with *Ariſtotle*, who ſaith, this *Medium* is double, to wit, Ayre and Water.

Confirmed. What is the *Medium* of Smelling.

Concerning the ayre, it is without controuerſie the *Medium* of Smelling becauſe when we draw our breath, we do at the ſame time alſo Smell, & beſide the Odour that exhaleth out of the mixt body, is not diffuſed into all dimentions, but only that way which the ayre is diffuſed. A certaine ſigne that the ayre is both the *Medium* and the vehickle of Smels.

The ayre approued.

Concerning the water *Placentinus* maketh ſome doubte, although *Ariſt.* in his 2 Booke *de Anima*, & eſpecially in the 8 chap. of his 4. Booke *de Hiſtoria animalium*, doth ſtriue earneſtly to proue that to fiſhes, the water is the true *Medium* of Smelling. His foundation is, that thoſe creatures which liue in the water do Smell, which if it be ſo, it is neceſſary that there muſt be alſo a *Medium*, wherein the Obiect ſhould be tranſported. That *Medium* cannot be Ayre, for ayre as ſoone as it is generated in water, doth exhale or bubble vp, as the ſame *Ariſt.* teacheth in the 5 chap. of his Booke *de Senſ. et Senſil.* from whence he concludeth, that for Fiſhes the water muſt needs be the *Medium*. And truly the conſequence were certainely and vndoubtedly good, if the foundation and ground where-vpon he raiſeth it be true. But we haue called that into queſtion before. Now I will adde only one argument, and that taken from the Nature of a *Medium* on this manner. All Odour hath his exiſtence in ſiccity, & therefore requireth alſo a *Medium* that is dry, leaſt the Obiect ſhould looſe his odour, for it is the office of the *Medium* to conſerue the Obiect, but water being moyſt is no way fit to conſerue the dry Odour, in reſpect of the contrariety betwixt them, vnleſſe a man will be ſo debaſed as to ſay that one contrary can be the *Medium* vnto the other, which is as much as if he ſhould affirme that contraries doe not mutually impugne, but cheriſh and foſter one another. Seeing therefore water which is moyſt muſt needes extinguiſh or diſſolue the Odour which is dry, it cannot poſsibly be a competent *Medium* for it. Hence appeareth the inualidity of *Ariſtotles* foundation, to wit, that Fiſhes doe Smell. It remaineth therefore that the ayre onely is the *Medium* of Smelling.

The water queſtioned. *Ariſtotle* for it.

Placentinus againſt it.

QVEST. LIII *After what manner an Odour affecteth or changeth the Medium.*

IT is a great controuerſie amongſt the Maſters of Philoſophy, how the odorable Obiect doth change the *Medium*, that is, whether that alteration be *Reall* or *Intentionall*. *Auerhoes* impugning *Auicen*, ſaith, it is done *Intentionally* as a colour is made of that which is coloured, and hee reaſoneth on this manner. If the Odour ſhould bee tranſported through the ayre together with a body, then would there be a penetration of bodies which is impoſsible to be and abſurd to ſay. But *Auerhoes* is deceiued, becauſe an Intentionall Obiect cannot really moue the Senſe; Now it is manifeſt that we Smell really. That which he obiecteth concerning colour, wee haue diſputed already in the precedent controuerſies. Adde hereto that Intentionall *Beings* are produced from the Soule, and doe depend thereon, and therefore they are called *Entia rationis* Notions of Reaſon. By this conceſsion therefore it would follow, that the Obiect is in the vnderſtanding before it is in the Senſe, if it were true that a Reall obiect did make an impreſsion of an *Intentionall* Odour in the *Medium*.

Did not *Auerhoes* remember that ruled Axiom, *Nihil eſt in intellectu quod non prius fuerit in Senſu? That there is nothing in the mind which is not firſt in the Senſe?* And to what purpoſe ſhould any thing that is in the vnderſtanding be remitted or returned vnto the Senſe, ſeeing things are therefore receiued into the Senſe, that they might attaine vnto the vnderſtanding. And whereas *Auerhoes* ſaith, that there would be penetration of bodies, if the odorable Obiect did really alter the *Medium*. I anſwer the conſequence is not good: for the ayre being a moſt liquid Element, doth eaſily yield to any body. Adde beſide, that a fumid exhalation being mingled with the ayre, may be caried and recaried with it hither and thither. After this manner alſo, the opinion of *Philoponus* and *Iandunus*, may bee refuted, who doe affirme that the Odour may really together with the exhalation be caried a good ſpace through the *Medium*, marry the reſt of the *Medium* which attayneth vnto the organ of Senſe, is altered onely intentionally by the Odour, for a reall Being doth alwayes worke really, and that which is Intentionall dependeth vpon our vnderſtanding. But if ſome part of the *Medium* were really changed, and other parts intentio-

Philoponus & Iandunus refuted.

nally. What is the reason why in remote distances a great tract of the *medium* is really affected; and in little distances (as when we moue the obiect to our Noses) but a little.

As also *Aegidius.*

Aegidius was of opinion that the odour was really produced in the *Medium* as is the Sound, which sayth *Placentinus* is vtterly false, for not so much as colour, which is simply and immediately made out of the mixtion of the first qualities, can possibly after any manner be receiued in the ayre. How then shall odour which is a second quality bee generated in the ayre. Furthermore. *Second qualities cannot mutually worke one vpon another*: for one white cannot produce another white, no more can one odour which expireth or breatheth out of a body beget another odour in the *Medium*.

With *Ammonius & Boetius.*

And for this cause we also most disclaime *Ammonius* and *Boetius*, who say that an odour may passe out of one subiect into another; for although it proceede together with the exhalation out of the bodies into the ayre, yet it doth not change his subiect nor flit into another. But the ayre being made vapoury sustayneth the exhalation together with the odour, conserueth it and is a vehickle vnto it: yet when the vapour is dissipated the odour vanisheth together therewith, which would not happen if it were fit to flit or moue out of one subiect into another.

Auicen redeemed.

Wee therefore with *Auicen* doe resolue that the *Medium* is really changed: for that the odour doth really yssue out of the mixed body we haue proued before: from whence it followeth necessarily that some part of the *Medium*, to wit, that vppon which the odoriferous exhalation doth immediatly worke is really affected. Againe, Odours doe really

The *Medium* is really affected.

attaine euen vnto the braine, and therefore there is no question but that the *Medium* is really affected. Those therefore that say it is affected intentionally, as also those that confesse some part of it be affected really, but other parts intentionally, haue sit downe beside the Cushion.

For they really affect the braine.

But although the odour proceede really out of the subiect and reach really vnto the braine, yet no man must conceiue that the odour is diffused through the whole *Medium* from the obiect euen vnto the organ, but it is wafted vpon the wings of the wind or transported by the motion of the ayre. That an odour attayneth really vnto the braine may be proued; because such odours do sometimes helpe and sometime hurt. The detriment seemeth not to proceed from the odour but from the quality of the subiect which accompanieth the odour, that is, the exhalation. For the odour being a quality cannot haue in it that hurtfull quality vnlesse you will graunt that a quality can bee in a quality. Neither

Confirmed by a strange instance.

doeth the quality onely of exhalation affect the braine, but sometimes some seedes of the very substance of bodies that are of subtle partes are transported in the exhalation, which setling in the braine brings foorth fearefull accidents and strange effects, as it did in him who smelling oft vpon Basill had a Scorpion bred in his braine. It is therefore necessary

Science is from the Senses.

we should beleeue that the odour is really *perceiued* by the organ. For confirmation wherof wee may also adde this argument, because all knowledge or science hath his originall from the Senses. Now science is of a reall not of an intentionall Being. How then shall science which hath a reall subiect take his beginning from the Senses if they receiue nothing but that which is Intentionall.

It is therefore manifest that the Senses doe not *perceiue* their obiects intentionally but really; and by consequent that the *Medium* is also really affected.

Obiection.

But it may be obiected if the odour be really imprinted in the Organ, then there is no neede of an externall *Medium*, and beside, that *axiome* will be false, That the obiect vpon the Senses doth not make Sensation.

Solution.

We grant indeed that there is no neede of a *Medium* which should be betwixt the reall odour and organ, but the vse of the *Medium* is for the conseruation, preparation and transportation of the odour.

QVEST. LIIII, *What is the true and principall Organ of Smelling where Aristotle is confuted.*

Galen hath often testified that in euery perfect Organ, there may be obserued diuers kinds of parts. Of these parts some bee principall, to which the action is primarily to be attributed. Some againe bee such which make the action more excellent, and others doe conserue the action.

Now that the Nose is the Organ of Smelling no man will deny, but be-

cause

cause diuers parts doe coucurre vnto the constitution of the Nose, to wit, bones, gristles, muscles, small nerues, membranes, and the mammillary processes; it is therefore controuerted betwixt the Physitians and Peripateticks to which of these parts, as to the chiefe cause, the action is to be ascribed.

A difference betweene the Peripateticks & Physitions.

Aristotle in his second booke *de Anima*, and in his booke *de sensu & sensili* doth affirme that the externall Nose which is conspicuous in the face, is the chiefe Organ of Smelling; wherein he conceiueth there is a couer like a value which is neuer opened, but by inspiration, whence it is that we haue no Sense or preception of odours but when wee inspire.

Galen in his booke *de odoratus Organo* doth in the three and foure whole chapters vehemently inueighe against *Aristotle*, where hee teacheth that indeede the externall Nose doth something conferre vnto this sense of smelling, but the chiefe Organ thereof is within the scull; And for the confirmation of this conceite, he vseth an elegant and inuincible demonstration from the enumeration of the seuerall pars of the Nose. For, neither saith he, can the bones, nor the gristles, nor the membran, nor the nerue dilated through the membrane be the true organ of the Smell, and therefore no externall part of the Nose can bee. As for the bones and gristles they are so farre from hauing the Sense of smelling that they haue not so much as the faculty of Touching allotted vnto them; they therefore are farre vnfit for the performance of this function. Againe, euery ἀφὴ or Organ ought to communicate in nature and conformation with the sensible thing, that so the Organ might bee more easily altered by it. But nothing is agreeable to the nature of Odours, but that which is vaporous: betwixt the nature whereof and that of bones and gristles, there is very great distence.

Galens demonstration.

As for the membrane which inuesteth the Nose; it is indeed endowed with most exquisite Sense of Touching, yet it is to crasse and thicke, for the reception of such subtle obiects as odours are. And beside this membrane or coate is also common to the Tongue and the Palate and mouth, but in those parts it hath no Sense of odors. Again if this membrane were the true instrument of Smelling, then it should continually perceiue the appulsion or beating of the odours, but there is no preception of odours, except when we do inspire; for though you fill the Nose full with Muscke or Ambergreese or other odoriferous bodyes; yea though you should annoynt the whole membrane with sweet oyles, yet you shal haue no preception of odors except you draw in the Ayre by inspiration; wherfore we conclude that the principall Organ of Smelling is not placed in the bone or gristle or membrane, or any other part of the externall Nose.

The membrane is not the instrumet of smelling.

As concerning that couer or value (whereof this great Phylosopher dreamed) which is open when we draw in our breath, and shuteth when we hold our breath, *Galen* doth in no sort acknowledge it in the aboue named places, neither will any well skilled in Anotomy admit of it. But yet put the case that there be such a value in the interiour part of the nosthrils and that it doth sometimes open it selfe to make a passage for the ayre and vapors which we draw in, and that it shuts againe when we cease our inspiration, then surely the motion of this couer must either be animall or naturall, or violent. That it is voluntary, no man will say, because there is no neede of such a value vnto animall motion. And beside all animall motion is at the command and in the gouernement of the soule, and obedient vnto our will and appetite, but this value is neuer opened but when wee draw in the Ayre. Moreouer, the immediate instrument of voluntary motion is is a muscle, but there are no muscles to be found in the depth of the cauity of the nosthrils.

That there is no value. Reason.

Neither is this motion Naturall as is the motion of the values of the heart. For the heart is perpetually mooued and performed by it owne instinct and not by our will.

If you thinke it be violent because it is forced by the inspired Ayre, then giue care vnto *Galens* obseruation ouerthrowing this conceite. For, saith he, if you shall force either much ayre or any liquour into the nose through a pipe and hold your breath, why is not the value opened if there be any such extant, and why should there not be a perception of those odours in the Nose. If the Perepatetickes shall insist, & retort our owne argument, and fight against vs with our owne weapons, and say, if the Mammi lary processes bee the principall Organ of Smelling, why doth not sweete Ayre being driuen with force and violence through a pipe moue the Sense.

Obiection. Solution.

Galen answereth, that the aire being blowne and forced through a pipe, if we hold our breath doth neuer reach vnto the Braine, because all partes of the Braine are full of Ayre

when the Braine is contracted by expiration, but when the Braine is dilated by his inbred power all the ſpaces are enlarged, and ſo for the auoiding of vacuitie are filled with inſpired aire. The aire therefore cannot attaine vnto the proceſſes and Ventricles of the Braine but onely by inſpiration, becauſe except the Organs be dilated, how ſhall the aire paſſe through thoſe pores which be already full of aire? Now if aire cannot bee brought but by Inſpiration vnto the Mamillary proceſſes, then ſurely cannot the ſpecies or kindes of odours: for as the character and quality of the ſound cannot bee carried vnto the Organ of hearing but by the meanes of the intermediate aire, no more can the qualitie of odours attaine vnto the organ of Smelling. Let *Ariſtotle* therefore patronize his owne opinion himſelfe.

The true Organ of ſmelling.

VVe with *Galen* and the Phyſitians do reſolue that the principall organ of the ſmell is ſeated within the Scull and a portion of the Braine, namely, thoſe proceſſes & two bunching productions which are like to the Nipples of a womans pap, and doe reſide or reſt vpon the higheſt bone of the Noſethrils.

The Mammillary proceſſes Authoritie.

And this hath *Hippocrates* bewrayed in his Booke περὶ ἀρχῶν, where he ſaith. That the Braine doth ſmell the odour of dry things together with the aire, drawing the ſame thorough two cartilagineous or griſtly bodies. And to him doth *Galen* beare witneſſe in his booke *De Odoratus Organo*, in his eight booke *de vſu partium*, and in his firſt booke *De Sympt. Cauſis*. And laſtly ſound reaſons doe alſo euince this our opinion. Firſt, that part is to be accounted the principall which hath a peculiar ſubſtance, figure & compoſition,

Reaſons proouing this firſt

VVitneſſe *Galen* in his ſixt booke *de Placitis Hippocratis & Platonis*. But the proceſſes amongeſt all the partes of the noſe haue a peculiar nature, figure and compoſition, which you cannot finde in any of the other. But the Bones, Griſtles and Membranes are euery where alike. Wherfore the principall cauſe of this action of Smelling is to be aſcribed to the Mammillary proceſſes.

a Reaſon

Againe, there is no part in the noſe which can be altred by odors, but theſe proceſſes being full of ſpirits and vapours doe with facility receiue the ſpecies of odours, and becauſe they are of neere a kin to the Nerues, they haue a kinde of Notion of that qualitie which they perceiue.

Auerrhoes. diſprooving *Galen*. First reaſon

Auerrhoes being a bitter enemy to Phyſitians in the defence of Ariſtotle endeauoureth to ouerthrow this opinion of *Galen* but with verie eaſie Engines. If (ſaith hee) the Mammillary proceſſes were the organs of Smelling, then the odor of thoſe things which are bruiſed in the mouth would be ſmelt when the Noſethrils were obſtructed and ſhut, becauſe there is a manifeſt paſſage for the aire open from the mouth & palate vnto thoſe proceſſes.

Second.

Moreouer, the odour of thoſe meats which are contained in the Stomack would be perceiued, for there do certaine vapours exſpire therefrom vnto the Braine, during the whole time of the concoction. And laſtly, ſuch creatures as wanted theſe proceſſes would alſo want the ſenſe of Smelling. But I thinke we may fully ſatisfie theſe obiections on this

Third. *Galens* anſwer

manner. Firſt, although there bee a way open out of the mouth into theſe proceſſes, yet notwithſtanding there is not any perception when the noſethrils are ſhut, becauſe the odours ſhould firſt be offered vnto the Noſethrils and there be prepared, without the noſethrils therefore there can be no perception of odours, and yet it dooth not follow that the Noſethrils therfore are the principall organ of this Senſe. Euen as without the watery humour no viſion can be made, and yet no man will ſay that it is the principall Organ of Sight.

Why we doe not feele that which is in our mouth & Stomacke

But beſides this, there is another reaſon why when our noſes bee ſhut, thoſe thinges which are chawed in the mouth and are contained in the ſtomacke are not ſmelt, to wit, becauſe the odour being as it were drowned and ſtrangled with the exceſsiue humiditie of the mouth cannot make ſhew of it ſelfe, nor imprint his natiue ſpecies and forme in the Senſe of Smelling. For Odour is (as *Ariſtotle* himſelfe in the ſecond Booke *de anima* affirmeth) of a drie thing, as a Sapor of a moiſt thing. So thoſe which are troubled with the *Coryza* or a diſtillation out of the head into the noſe which we call the *poſe*, doe not perceiue the formes of odours.

Moreouer, that vapour which is brought from the Stomacke vnto the Braine is not perceiued by the Smell, becauſe ſuch vapours are too familiar and too well acquainted with the Braine, ſo that no alteration can be made by them. In like maner thoſe which vſe to eate much garlicke haue no ſenſe of their owne ſtinking breath.

As

As for *Auerrhoes* his laſt obiection, that many creatures wanting theſe proceſſes, yet do perceiue the ſauour of odours, is not any whit repugnant vnto *Galen*. For he ſpeaketh onely of perfect creatures, and not of imperfect, which as they can ſtand without bones and liue without Lungs, ſo there is no reaſon but they may reſpire and breath without noſthrils or theſe Mammillary proceſſes. The concluſion.

We conclude therefore that thoſe two ſwelling mammillary proceſſes are by good right accounted the principall organs of ſmelling, yet notwithſtanding wee affirme that there canne bee no perception of odours without the help of the noſthrils and the ſpongy bone. And thus much of the Senſe of Smelling. Now we proceede vnto the Taſt.

QVEST. LV. *Whether Taſte be the chiefe action of the Tongue.*

ALbe it be commonly knowne that the Taſte is an action of the Tongue, yet it ſhall not bee amiſſe to make this truth ſomewhat more manifeſt, for the Tongue is ordayned for many vſes. Firſt to articulate the voyce. Secondly, for maſtication or chewing, becauſe it contayneth the meate within the mouth, and rowleth it vnder the mill-ſtones of the Teeth. Thirdly, for the Taſte and dignotion or perception of ſapours. The queſtion therefore ſhall bee, which of all theſe is the principall action for which Nature ordayned this inſtrument, becauſe we aſsigne vnto one part but one principall action. That therefore is the principall action, for which the Tongue was primarily inſtituted by Nature. And that Action is primary which is moſt neceſſary, the rule of Nature being firſt of all to prouide for the neceſsity of the creature. The action therefore which is moſt neceſſary is alſo the principall action. The diuers actions of the tongue. Which action is principall.

I know well what great vſe we haue of ſpeech, and how miſerable the life of a dumbe man is, yet becauſe other actions are more neceſſary, therefore wee cannot beleeue that ſpeech was the principall end for which Nature ordayned this Organ. Now that other functions are more neceſſary then ſpeech we need not to doubt, becauſe thoſe are abſolutly neceſſary to life, this onely to better life. That the other functions are abſolutely neceſſary, for the conſeruation of life is hence manifeſt, becauſe brute beaſts cannot liue without them as they doe without ſpeech. Speech is not the principal action of the tongue.

But amongſt thoſe other functions, which is the moſt neceſſary, is harder to diſcerne, yet to ſay truly maſtication is not an action of the Tongue, and therefore wee will not ſtand in this place to diſpute the neceſsity of it. For it is an inſtrument of maſtication but by accident, as it rowleth the meate vnder the Teeth that chew it. But a principall action belongeth not to a part by accident, but by & of it ſelfe. Again, it were abſurd, to ſay that the principall action of ſo noble a member, did but helpe the Teeth to chaw the meate. Adde hereto that maſtication or chewing is not ſo neceſſary to life as Taſting is for Infants doe ſwallow their meate without chewing, and ſo doe moſt Fiſhes, as *Ariſtotle* remembreth in the eleauenth chapter of his booke *de partibus Animalium*, but without Taſte the creature cannot liue. Not that if their Taſte be loſt, they muſt preſently peniſh, (for it was a cuſtome among the Ancients for blaſphemie to cut out mens Tongues and yet they died not) but becauſe all creatures taking delight in ſome one kinde of food or other, when the Senſe of pleaſure is taken away, they abſtaine from thoſe meates, or take but little and ſo pine away to death. And this is the opinion of other men concerning the neceſsity of the Taſte. I, ſaith *Placentinus*, doe rather thinke it therefore neceſſary, becauſe when it is loſt the creature taketh all meates indifferently, & by that meanes is often extinguiſhed by poyſon in ſteede of nouriſhment. Seeing therefore that perpetuall nutrition is abſolutely neceſſary vnto life, therefore Nature ordayned this Senſe, to take the aſſay, which was fit ſhould be very exquiſite, becauſe the Lord it ſerueth, which is Nutrition, was the principall act for which the creature was ordained. Nor Maſtication. Reaſons why The neceſsity of the Taſt. An old kind of puniſhment of Blaſphemy. The reaſon of the neceſsitie of the Taſt.

We conclude therefore that of all the actions of the Tongue the Taſte is the chiefe, and that the reſt are but ſeruants and attendants there-vnto, eſpecially Maſtication.

QVEST. XLVI. *Whether the Taſte differ from the Touch.*

THE Taſte is one of the fiue external Senſes, whereby we diſcerne the differences of ſapours. This Senſe hath great affinity with the Senſe of Touching, in ſo much that ſome haue made no diſtinction betweene them, but haue placed the Taſte vnder the Touch, as the *ſpecies* vnder the *Genus*, for which they haue not onely *Ariſtotles* authority, but very ſtrong reaſon. What Taſt is and how neere a kin to touch

The

The authorities they produce are theſe. *Ariſt.* In the ſecond Chapter of his booke *de Senſu et ſenſili* ſaith, that the Taſte is a kinde of Touching. Againe, in many places he affirmeth that Taſte is a kinde of Touching, as in the 4. chap. of the Booke before named. In the 64 Text of his third Booke *de anima*. In the 17 chap. of his 2 Booke *de partibus animalium* & in infinite other places. But theſe authorities ſeeme not to bee of any great conſequence, becauſe the ſame Ariſtotle doth oftentimes affirme that all ſenſe is a kinde of Touching; from whence it would as well follow that there is but one Senſe, that is, the Touch, then which nothing can be more abſurd. Wee muſt not therefore conclude that the Taſte and the Touch are all one, becauſe *Ariſtotle* ſaith, that the Taſte is a kinde of Touch.

Ariſtotles authorities.

Called into queſtion.

It ſeemeth to me notwithſtanding that there is ſomething in it, why particularly intreating in diuers places concerning the Taſt, he calleth it rather a Touch, then the other Senſes, eſpecially in his propper Tractate of this Senſe, whereas he giueth no ſuch attribute to any other of the Senſes. For in his chapter *de viſu* he doth not ſay that Seeing is a kinde of Touch, nor ſhall you finde in the Chapters of Hearing and of Smelling any ſuch matter. Further, this opinion is confirmed by *Ariſtotles* argument, becauſe he aſcribeth the ſame obiect to both theſe Senſes; for in the very beginning of his Chapter *de Guſtu*, that which is Guſtable or fit to be Taſted, is alſo Tangible and fit to be Touched. And comparing the Taſt with the Touch that there is the very ſame reaſon and nature of them both Yea, that they differ nothing one from another. But in the 28. Text of his 2 booke *de Anima*, hee ſpeaking of ſet purpoſe auoucheth the very ſame, for hee ſayth not onely that that which is Guſtable is alſo Tangible, but alſo that the Touch is the Senſe of Aliment. And about, the end of the ſame text expreſſely naming the obiect of Taſt, hee ſayth, that a *Sapor* is one of thoſe which are *perceiued* by Touching. And in the 63. text of the ſame booke more playnly thus; *Wherefore the Taſt it ſelfe is a kinde of Touching, for it is the Senſe of aliment, now aliment is a body which is perceiued by the Touch.*

And expounded.

If therefore Taſting and Touching haue one and the ſame obiect, ſurely they are one and the ſame Senſe. As from the plurality and diuerſity of obiects, the plurality and diuerſity of the Senſes is gathered, ſo from an vnity and Identity of the obiect it muſt needes be there ſhould follow alſo a vnity and Identity of the Senſe.

They adde alſo an argument gathered out of *Ariſtotle* in the beginning of his Chapter *de Guſtu*, on this manner Taſt and Touching doe equally perceiue that which is moyſt, yea moyſture though it be inſipide ſome ſay may be diſcerned by the Taſt. Seeing therefore the obiect of the Touch may be perceiued by the Taſt. And the obiect of the Taſt reciprocally by the Touch, they muſt not be eſteemed diſtinct Senſes.

Finally, they adde out of *Ariſtotle* that in the 23. text of his ſecond booke *De anima* and in the 68. text of the third booke he ſaith, that the Touch onely is neceſſary for the creature. And againe, in the fourth chapter of his booke *de ſenſu & ſenſili*, as alſo in the laſt chapter ſaue one of the third booke *de anima*, he ſaith, that a creature cannot bee without the Taſt; wherefore ſay they, *Ariſtotle* thought that the Taſt and the Touch were both one, otherwiſe there ſhould be a repugnancie betwixt theſe two places.

All theſe particular inſtances out of *Ariſtotle* doe at the firſt bluſh ſeeme to proue that he was of their mind. But if we looke ſomewhat more narrowly into them we ſhal finde that there can bee no ſuch thing gathered from *Ariſtotle* by good and lawfull conſequence.

Anſwer to *Ariſtotles* authorities.

For firſt whereas he ſaith that the Taſt is a kinde of Touch, it is nothing elſe but to demonſtrate the affinity betwixt theſe two Senſes; for if hee had meant that the Taſt and the Touch did not differ in *Specie*, hee would neuer haue ſayd that *Guſtus* was *Tactus quidam*, but ſimply and plainly *Guſtus* is *Tactus*, hee would not haue ſayde that Taſt is a kinde of Touch, but that Taſt is a Touch. Neither are wee to wonder why *Ariſtotle* ſpeakes in this maner rather of this Senſe then of any other. Is it not becauſe none of the other Senſes haue any ſuch acquaintance or familiarity with the Touch as the Taſt hath?

To the firſt inſtance.

Conſider firſt that the Taſt as alſo the Touch is made without a *medium* ſo are not the reſt of the Senſes. The reaſon is, becauſe as well in the Taſt as in the Touch the obiect muſt touch the Organ, ſo that theire extreme parts are contiguous one vnto another. Hence it is that the Guſtable obiect being aboue that which Taſteth, maketh Guſtation, whereas in other Senſes there is no comprehenſion of the obiect by the Organ ſauing by the interpoſition or mediation of a *medium* or middle body.

The affinity betwixt the Taſt and the Touch.

Finally the obiect of the Taſt is more endowed with Tactile qualities then the

iects of the reſt of the Senſes as being more corporeall, materiall, earthy, and to ſpeake in a word correſpondent or anſwerable to the Tactile obiect, ſo that *Ariſtotle* might well ſay, that that which was Guſtable was a kind of Tangible. Seeing therefore this Senſe of Taſting hath ſo many more conditions concurring with the Touch then the other Senſes, it was not without cauſe that *Ariſtotle* ſo often compared the Taſt and the Touch, and in a manner of ſpeech confounded them. but was more ſparing in the collation of the Touch with the other Senſes. And hence we may ſhape an anſwer to the ſecond authority, for he doth not ſay ſimply *Guſtabile eſt Tangibile* but *Guſtabile eſt quoddam Tangibile*, adding a conditional particle wherby he would intimate that there was a great vicinity or neighborhood betwixt theſe two kinds of obiects, yet notwithſtanding that they did ſo differ that they do not fall vnder one and the ſame Senſe. Anſwer to the ſecond inſtance.

The third argument is weighty and difficult, for without any condition or limitation he ſaith, that a Sapor is perceiued by the Touch, and that the Touch is the ſenſe of Aliment; notwithſtanding we anſwere that *Ariſtotle* doth not take a Sapor as it is a qualitie properly Guſtable, but as it is in a guſtable body. For this body is indeede perceyued by the Touch not as it is Guſtable, but in reſpect that beſide the Sapour it hath alſo many Tangible or Tactile qualities. To the third. First Anſwere

Add moreouer, that the word χυμὸς which *Ariſtotle* vſeth, doth not onely ſignify a Sapor but alſo a iuice and humor indued with a Sapour, whence the Phyſitians call thoſe meates εὐχύμους, not which are well-taſted but which yeelde a profitable and Alimentarie blood vnto the bodie: againe on the contrary they call thoſe meates κακοχύμους which yeeld a bad and vicious iuice, and that diſeaſe is called κακοχυμία, when the body aboundeth with euill and vicious nouriſhment. VVe are therefore to beleeue that *Ariſtotle* is thus to be vnderſtood, becauſe ſo oftentimes hee teſtifies that *Sapor* hath his reſidence or beeing in humidity, or that which is humid and moyſt. The 2. anſwer

I might alſo ſay that *Ariſtotle* ſpeaketh in that place of that Sapour which nouriſheth. Now a Sapour as it is a Guſtable quality doth not nouriſh, becauſe that which is incorporeall cannot be turned into a body, but that which nouriſheth muſt of neceſsity bee conuerted into the body that is nouriſhed. It is therefore no queſtion but that when Ariſtotle ſpake of a *Sapor* he meant it *de corpore Sapido*, that is, of a body which was not without Sapors or Taſtes. And indeede a Sapid body may nouriſh. So ſaieth *Auicen*, that which hath a good Taſte doth alſo nouriſh, not that the Sapor or Taſte dooth nouriſh, but the ſubſtance wherein the Sapor doth conſiſt. Third anſwer. *Auicen.*

On this manner alſo is Ariſtotle to be expounded, where hee ſaith, that the Touch is the Senſe of aliment, for he doth not meane that it falleth vnder the Touch and vnder the Taſte after the ſame manner and in the ſame reſpect but vnder the Touch in regarde of the Tactile qualities, vnder the Taſte in regard of the Sapor. It is as much therefore as if he ſaide, *Becauſe the Aliment as it is a body cannot be found without Tactile qualities; the Touch indeede perceiueth theſe qualities, but it perceyueth not th' Sapor as it is a Sapour*. And therefore in the 63 Text of his third Booke *de anima*, after he hath ſaide that the Touch is the Senſe of Aliment he explaineth himſelfe after this manner, *But the aliment is a Bodie which is perceiued by the Touch*. To the fourth

Seeing therefore the Aliment is a bodie, it muſt haue both Tactile and guſtale qualities, and therefore may be truely called the obiect both of the Taſte and of the Touch, yet is it the obiect of neither Senſe as it is an Aliment, but of the touch as it is moyſt and dry, hard and ſoft: of the Taſte, as it is ſweete, bitter, Salt and the like.

As for the reaſon which they alledge out of *Ariſtotle*, I hold it to be of no weight, becauſe *Ariſtotle* had no ſuch intention; yet we may grant that moyſture is perceiued by the Taſte not as it is moiſture, but as it is ſapid: and that inſapide moiſture or moiſture without Taſte may be diſcerned by the Senſe of Taſting, that I vtterly deny. To the Fifte.

Concerning the neceſsity; that which they vrge is meerely friuolous, for Ariſtotle ſupponeth that the Touch is ſimply neceſſary ſo that the creature without it cannot ſubſiſt: but the Taſte is neceſſary for the Touch, becauſe it is a kind of Touching: yet we do not denie but that the Taſte alſo is neceſſary *Secundum quid*, as we ſay in Schooles, that is not of it ſelfe, but becauſe the creature wanteth nouriſhment. It dooth not therefore follow that either the Taſt and the Touch ſhould be both one, or elſe that an imputation ſhould be caſt vpon *Ariſtotle* for contradicting himſelfe. To the Sixt.

It may be alſo obiected, that becauſe both the Taſte and the Touch are both in one & Obiection.

the

Solution.

the ſame Tongue, that therefore they ſhould be one and the ſame Senſe. But the conſequence is not good, for there is no organe of Senſe, which beſide his proper Facultie of Senſation is not alſo furniſhed with the Senſe of Touching. But becauſe the Sēſe of Taſting is not alwaies found where Touching is, and where it is found there is no other Faculty of Senſation. I conclude that not onely all the other Senſes but the Taſte alſo is a diſtinct and different Senſe from the Touch.

QVEST. LVII. *Of the obiect of Taſting.*

The obiect of Taſt is more euident then other ſenſes and why.

THe obiect of the Taſte ſayth *Ariſtotle* in the fourth Chapter of his Booke *de Senſu & ſenſili*, is not onely more euident and manifeſt vnto vs then the Odours are, but alſo then all other Senſible Obiects. The reaſon we may giue out of the ſame place of *Ariſtotle*, becauſe the Taſte is a kinde of Touching, which Senſe in a man is more perfect then all the reſt.

2. ſignifications of *Guſtabile.*

Now the Obiect of the Taſte is that which is *Guſtabile* or *Guſtile*, which worde ſignifieth two things, to wit, a Sapour or quality and affection ſeated in a ſapide body, and the body it ſelfe wherein the Sapour is. But the Sapour is the proper and adequated or proportionable obiect of the Taſte, and therefore *Ariſtotle* appropriateth the word *Guſtabile* to a Sapour. As ſayth he *viſibile eſt color, ſic Guſtabile eſt ſapor*, as that which is viſible is a Colour, ſo that which is Guſtile is a Sapour: as if he ſhould ſay, that a Guſtable body is no way Guſtile or to be Taſted, but onely in reſpect of his Sapour. Yet hee oftentimes puts *Guſtabile* for *Sapor*; the reaſon is, becauſe a Sapour hath no exiſtence of it ſelfe, neyther can it moue the Senſe but hath all his being and eſſence in the mixt body. That therfore which he calleth *Guſtabile* is a mixt body, which in reſpect of that quality which is called a Sapour is Guſtile or may be Taſted. Not but that a Sapour doeth by it ſelfe moue the Senſe, but becauſe it cannot ſubſiſt without the mixt body, for conſidered euen without the mixt body it may be ſayd to be the obiect of Taſt, becauſe it is it alone in the mixt body which moueth that Senſe.

QVEST. LVIII. *Of the matter of Sapours.*

What a ſapor is.

2. kindes of firſt qualities.

A Sapour is a quality ariſing out of the firſt qualities, which alone by it ſelfe is able to moue the Taſte. Now the firſt qualities are of two ſortes: ſome Actiue, as heate and cold; others Paſsiue, as moyſture and drought. Out of the Actiue qualities the Sapour hath his Efficient cauſe, to wit, heate; out of the Paſsiue his Materiall cauſe, to wit, Moyſture. But leaſt any man ſhould wonder why wee make moyſture which is nothing elſe but an incorporeall quality to bee the matter of Sapours. We anſwere, that wee vnderſtand humidity not in the abſtract but in the concrete. So that haply it were more proper to ſay *humidum* then *humiditas*, for to ſay trueth, a Sapour is not made onely of humidity, but of humidity ioyned with ficcity, yet ſo that the humidity is predominant.

Sapours are not made of ſimple humidity.

Wherefore *Ariſtotle* ſayth that a Sapour dwelleth in that which is moiſt, as an odour doth in that which is dry; yet he doth not name humidity alōe, nor ſimple ficcity but both conioyned, and therefore hee rather expreſſeth himſelfe by *humidum* and *Siccum* then by *humiditas* and *ſiccitas*: ſo that in the one the moyſture preuaileth ouer ficcity, in the other the ficcity ouer moyſture.

For thus much doth *Ariſtotle* intimate in his Booke *de ſenſu & ſenſili*, where he ſayth that the vniuerſall nature of Sapour is, that it is a paſsion of the Senſe of Taſting made by that which is earthy, dry, in that which is moyſt. Wherefore humidity being predominant in an earthy ficcity is properly the matter of Sapors.

1. Obiection

It may bee obiected if in Sapours the humidity muſt preuaile ouer the ficcity, then thoſe bodies wherein the ficcity preuailes ouer the humidity ſhould be inſipide and without Taſt. Now there are many in which the ficcity is predominant, as aſhes, Pepper, Ginger and ſuch like, which yet notwithſtanding haue a very ſharpe and quicke Taſte. Adde moreouer that if that were true, then Sapors ſhould not properly belong vnto Aliments; for *Ariſtotle* ſayeth in the 28. Text of his third Booke *de anima*, that hunger is an appetite of that which is hot and dry. An Aliment therefore is not moyſt but hotte and dry, becauſe it appeaſeth hunger. Seeing therefore all men confeſſe that Sapours doe properly belong to Aliments, it ſhould ſeeme alſo that Sapors haue their reſidence not in moyſture but in ſiccity.

2. Obiection.

VVe answere, that an Actuall Sapour, that is, such a Sapour which is instantly fitte to moove the Taste must necessarily bee in moysture. That which they obiect of Pepper, Ashes and such like, we answere on this manner. VVee grant that of themselues they are insipide and haue no Sapour but that which is potentiall, for they doe not Taste till they be chewed, and that is by accident: when as that humour which perpetually remayneth in the mouth and the tongue, prouoketh or produceth their potentiall vertue into Act, but because siccity is in them predominant, therefore they yeeld a sharpe and quicke Tast.

That which they add concerning Aliment is easily answered, For there are two kinds of Aliments; one which satisfieth hunger, another which satisfieth thirst. That which satisfieth thirst is exceeding moyst, and in respect of it that which satisfieth hunger may bee called dry, although it doe not follow that it should simply be dry, yea it is necessary that it should haue so much moysture as the Sense of Tasting doth require otherwise it could not satisfie hunger. Solution 2. 2. kinds of Aliments.

Finally, wahtsoeuer mooueth the Tast must of necessitie haue an inward moysture wherein it is steeped, although it hath no outward, the reason is that it may melt and diffuse it selfe through the organ of the Sense, for those things that are hard and cannot bee dissolued cannot moone the Sense of Tasting, as wee may conceiue by a rough and torrified tongue such as we see is chopped and blacke in violent Agues, which cannot make any certaine estimation of the difference of Sapors.

QVEST. LIX. *Of the efficient cause of Sapours.*

IF the passiue qualities therefore moysture preuailing ouer Siccity is the matter of Sapors. Of the actiue qualityes they haue heate for their efficient cause. For as the simple and pure Elements are of themselues without sapor or odor, so also in the mixt body no such thing would result out of them if euery Element should reserue his owne quality to himselfe; and therefore there is neede of heate to draw out the Sapors out of the concoction of the humidity and Siccity, by which concoction these two are fitly mixed one with the other, neither is it reason that any man should substitute *cold* to this office, for dayly experience teacheth vs that fruites when they are frozen, as Apples, doe vtterly loose their tast; yea although they be thawed and resume their former heate yet their tasts doe not returne. So that cold is so farre from being the efficient cause of Tast, that rather it doth vtterly destroy them. Adde hereto that no fruite attaineth his natiue Tast till it grow ripe, now this ripening is made by heat. It remaineth therfore that heate in as much as it concocteth humidity, and accomplisheth perfect mixtion is the true and onely efficient cause of Sapors. Heate is the efficient cause of Sapor. How that is. Cold cannot be. Why frozen fruits loose their Tast.

QVEST. LX. *Of the number and order of Sapors.*

Aristotle in the 4. chapter of his book *de sensu & sensili* going about to recite the diuers kinds of Tasts compareth them with colours not because there is any great affinty betwixt them, but because there is iust as many of the one kinde as of the other, and he concludeth them both vnder the number of seuen. Some say there are eight kindes of Sapours, and *Plinie* in the 21. chapter of his 15. booke, reckons vp thirteene. VVe with *Aristotle* will rather reduce them vnto the number of seauen; because, as there may be, and indeede there are infinite varieties of mixtion, so we should draw out of them infinite differences of Sapors, if it were possible accurately to number them; for nothing is so sure as that the differences of Sapors doe arise from the multiplicity of mixtion; for example, out of that wherein heate and moysture are abundant, a sweete Sapor; out of that that is hote and dry, a bitter and salt Sapor, and so in the rest, as this or that qualitie hath greater or lesse rule in the mixt body, yet alwayes moysture must haue the first place. How many kinds of Sapors. As many as of mixtures.

An instance of this we haue in a place of *Galen*, in the sixth, seuenth and eight chapters of his fourth booke *de simplicium medicamentorum facultatibus*. *The fruites of trees* (saith hee) *that appeare to vs to be sweete when they be ripe, are soure when they are young, and* [illegible] *of consistence, but in processe of time they become moyst, and their sowrnes turnes into sharpe-* [illegible] *which sharpenesse they loose by degrees as they grow ripe and at length become sweete.* An elegant place of *Galen* concerning Sapors.

Among these Sapors, Salt and Bitter are contrary to sweete, because being vnder the same kind there is the greatest distance betwixt them. *Aristotle* hauing a respect to white & blacke calleth them *priuatiues*, and that not without good cause, for although beeing vnder Salt and bitter are contrary to sweet

the

the ſame kinde they differ moſt one from another, yet they cannot bee truely ſayde to bee contraryes: for ſweetneſſe is generated in a ſubiect that is fulfilled with heate and moiſture, but ſalt and bitter are in a ſubiect which is hot yet very dry, and therefore the ſweete Sapor nouriſheth more then the reſt, yea we thinke that all other Sapors doe nouriſh onely by reaſon of their ſweetneſſe which lurketh in the ſecret bowels of the ſapide body, although by the Taſt it cannot be ſo manifeſtly perceiued. For all nouriſhment muſt bee conuerted into bloode that ſo it may become a fit nouriſhment vnto parts, but laudable and good blood is hot and moyſt and ſweete to Taſte to. That Sapor therefore vvhich hath the greateſt Analogy and affinity with bloode is fitteſt to nouriſh, and ſuch is the ſweete Taſte.

Sweet nouriſheth but no other.

Other Sapors which haue no ſweetneſſe at al in them are altogether vnfit for nouriſhment.

There are ſome which thinke that ſweete and bitter are not the extreme Sapors; grounding themſelues vpon *Plato in Timæo*, becauſe (ſay they) thoſe Sapors are to bee accounted extreames which come neereſt vnto the firſt qualities. But neyther ſweete nor bitter are ſuch, but *Styptick* or *binding* and *keene*, for the keene taſte or byting, ſuch as is in Pepper reſulteth out of a high degree of heate. The other which bindeth and contracteth the Tongue ariſeth from extreme cold.

That ſweete and bitter are not extreame Sapors. Arguments.

Againe, thoſe obiects that are extreme do hurt and offend the inſtrument; now ſweet doth not hurt but refreſheth it, yea it conſerueth the temper thereof by an acceptable pleaſure and delight. Another Reaſon may bee, why ſweete is not an extreme Taſte, becauſe from ſowre to keene the paſſage is by ſweete. So that whatſoeuer is keene or biting when it is ripe, and ſowre when it is greene, will haue a kinde of ſweeteneſſe in it before it come to his perfection. Now in qualities the tranſition is by the mediate or meane qualities not by the extreame. It is therefore to bee concluded, that not ſweete and bitter but ſowre and keene are the extreame Sapors.

But although we muſt needs confeſſe that theſe Arguments haue ſome life & ſtrength in them, yet we preſume that *Ariſtotles* opinion may well bee maintained. It is true indeede, that if you conſider Sapors according to their originall, that is, as they reſult out of the firſt qualities our aduerſaries haue concluded well. But if you regard Sapor without reſpect vnto their originall and ſimply as they are Sapours, that is, naked qualities which mooue the Taſte, then our Aduerſaries are in the wrong.

Refuted.

It may well be, that *Plato* vnderſtood the matter on this manner, becauſe he doth eſpecially attend to the temper of the body in which the Sapors are, but this is not the proper contemplation of Sapours. *Ariſtotle* who of purpoſe diſputed concerning Sapours vnderſtood them according to their proper Nature, to wit, as they mooue the Taſte for a ſweete and a bitter Sapor do mooue and affect the Senſe after the moſt contrary manner. So colours are not to be conſidered as they are nearer or further off, too or from the firſt qualities, but as they affect the Sight, and in this reſpect white and blacke are called extreame and contrary colours, becauſe they affect the ſight after a moſt contrarie manner, for white diſſipateth the Sight. *Black* congregateth and vniteth it.

Plato expounded. *Ariſtotle* defended.

Why Sapors are called extreame.

VVhereas they ſay that the keene and Stipticke Sapors do hurt the organ they are deceiued if they meane it in reſpect that they are Sapours; for the truth is, that the Offence commeth from the firſt qualities, to which thoſe Taſtes are too neere Neighbours. And this is the reaſon alſo why the paſſage is from ſowre to keen by ſweet, becauſe thoſe qualities are ſo changed in the mixt bodie, that after ſweete, ſowre doth ſucceed, & after ſowre keene or hot. Their conſequence would follow, if the ſowre Taſt ſhould engender ſweet, and ſweete ſhould engender that that is keene and hot, but there is no ſuch matter: for who did euer ſay that the ſecond qualities did ariſe one out of another? For they proceed not ſo much from their firſt qualities as from the condition of the matter. VVe conclude therefore, that becauſe the ſweete and bitter Taſtes as they are Taſtes or Sapors do after a moſt contrary manner affect the Senſe of Taſting, that therefore theſe are the extreame Sapors.

Anſwer to the ſecond reaſon

To the third.

Second quality ariſe not one from another.

Hauing thus reſolued which Sapors are extreame, let vs now a little conſider what are the intermediate, which with *Ariſtotle* we reckon ſix, *Fatt*, *Salt*, *Keene*, *Sowre*, *Sharpe* and *Tart*, which in Latine are called *Pinguis*, *Salſus*, *Acris*, *Acerbus*, *Acutus* & *Acidus*.

How many intermediate Sapors.

I liſt not to oppoſe *Pliny* or any man elſe that hath bene pleaſed to make more differences of Sapors, theſe are thoſe that are moſt manifeſt, and therefore Ariſtotle contented himſelfe

himselfe with them, the rest being very obscure or at least not knowne to such as this our labour shall concerne. Thus much onely we will admonish you of, that all the varietie of Tasts beside those we haue accoūted, do arise from the innumerable variety of mixtions, from the different constitutions of the orgā, as also from some secret & vnknown instincts which do recide in particular bodies, whereof to say truth we can giue no reason at all. Why they are infinite.

VVherefore becauſe the Sapours themselues are infinite, their proportion very diuers, and their causes so transcendent, it is not posible to make any definition or description of them to any purpose, who can deny but that some creatures, yea some men doo vehemently desire bitter things and abhorre that which is sweete? are bitter things therefore sweete to the one and sweet things bitter to the other? You will say no, because the difference ariseth from the diuersity of his Temperament that Tastes it. I confesse it, but seeing there are almost so many diuers Temperaments as there are *individua* or particular creatures in the world. I would aske the question whether it bee posible that so many different kinds of Sapours may be reckoned or deduced from them? By no meanes: no more is it posible to define them. All Sapors cannot be defined.

VVherefore if you looke into the vulgar diſcriptions of Sapours you shall finde them full of errours. *That* (say they) *is sweete that doth affect the Sense best, that is bitter which affects it worst.* A definition of sweet and bitter.

Neither is true, for if that which is bitter did affect the Sense worst, no man would desire it, no man woulde take pleasure in it; for that which peruerteth the harmony of the Sense, can in that respect and least bee pleasaunt vnto him, but that which doeth affect the Sense worste must needes make the instrument to iarre, and yet wee knowe that many men (not to speake of other creatures) do wonderfully delight and vehemently long after those things which are bitter. Refuted.

Againe, if sweete were that which affecteth the Sense best, then should it please all men, yea all creatures, for that which affecteh the Sense best wee should most reioyce in, which notwithstanding we finde to be contrary often times in our selues, when nothing is more irkesome vnto vs then that which is sweete and lushious.

But some men may aske me if I do not like these definitions, how I would haue sweet and bitter defined. I answere as I a sayd before that they cannot bee defined; for accidents doe not fall vnder definition, especially second qualities which are more accidentary then the first: and therefore I thinke they cannot bee so much as described, vnlesse you will take that for a description which is most common, and when there happeneth any exception it shall be sayde (and that more truely then they are aware) that it happens by accident, that is to say, not because the Taste doth not agree with a discription, but because there is some Salt in the Organ which doth not perceiue the Sapour as it is. Obiection.

Well, wee will confesse that these Sapors being the extreames, may fall vnder some such rude discription as is before exhibited; but whose pensill can drawe so fine a line as to describe the intermediate Tastes? Shall wee make one for all, and say that those are intermediate Sapors which affect the Taste after a middle mannner? Answere.

Surely this definition had not neede to bee scanned in the Schooles, being made at random or at large without any causes or signes of causes therein.

Much better it is in my opinion to note them out by examples or instances, as *Galen* hath wisely done in the eight and ninth Chapters of his fourth Booke *de simpto. medicam.* facult. Sapors are best declared by examples.

A sweet Sapour therefore doeth consist in a matter aboundantly moyst and moderately hotte: as are Figges, Hony, ripe Grapes, sweete and mellow Apples and such like. Sweete.

The bitter Sapour recideth in a very crasse and thick matter; hot indeed but easily moyst, or rather dry as VVormwood, Gall, Aloes and such like. Bitter.

A fat Sapor consisteth in a thin matter and ayrie, which also is temperate in the first qualities as in Seame, Marrow, Oyle, Butter & such like. Fat.

A salt Sapor consisteth in a dry matter, as in Salt, Ashes, Gunpowder and the like. Salt.

A keene Sapour is in a substance whose parts are thin and subtle, yet moyst and the temper hot; such a tast in Garlick, Onions, Raddish and the like. Keene.

A sowre or which also they cal stipticke and *Sapor pontieus*, but I knowe not why, is in a crasse and cold matter, as in vnripe Apples & Berries or such like. Sowre.

An acute or byting Sapor is when the parts are thin, dry and hot, as Pepper and Ginger. Acute.

The sharpe is in thin parts but cold, as in Vineger, Lemons, oyle of Vitreall and such like. Sharpe.

Finally, you may with me obserue that no man for ought I know hath hitherto sufficiently described these maister Sapours, or not so much as giuen them apt and fit names.

The confusion whereof do make the discourse of them tedious to the Reader. Onely *Galen* hath chalked out a faire way, wherein if we carefully insist, haply this labyrinth may at length be troden out. VVe conclude therefore, that if it be impossible rightlie to define these heads, hard to describe them, very difficult to giue them proper names; what an infinite taske were it to vndertake an exact discourse concerning all the particular differences of Sapors?

The confusiō of our authors about the Sapor.

QVEST. LXI. *Of the Medium or Meane of Tasting.*

WE are againe falne into a harde and intricate way wherein none of the Ancients or of the new writers haue beaten out a pathe vnto vs, and that is concerning the *medium* of Tasting. *Aristotle* was in a great suspence concerning the *medium* of Touching, neither did he determine any thing thereof. In like manner concerning this of Tasting he hath vtterly forsaken vs. And I wonder much (saith *Placentinus*) that amongst all the Philosophers there is not one that hath insisted in this disquisition to finde out the trueth; but those that haue particularlie made Tractates of this Sense haue notwithstanding balked this argument, not considering that in euery Sense there be three things especially to be stood vpon, the Obiect, the *Medium* and the Organ.

The difficulty of this Quest.

Concerning the obiect and the Organ all men do agree, and the crie is vniforme and current. But for the *Mediū* there all the whole field is at a losse. Haply the difficultie of the Disquisition did affright them, for otherwise the contemplation is not vnpleasant. *Aristotle* toucht vpon it in the 101. Text of his second Booke *de anima* where he saith, That the Taste hath no externall *Medium* becausе it is a kinde of *Touching* which it selfe hath no such *Medium*. Beside this, he hath nothing of this matter, notwithstanding we wil aduenture to put forth our selues vnder the censure of this carping age, which if we shall not satisfie, yet

Philosophers faile therein.

Arist. toucht vpon it.

Si non datur vltraeſt, aliquid prodire tenus.

If further foorth we cannot go,
Yet something 'tis the way to show.

And haply he that comes after, as it is in new discoueries, may not repent him that wee haue sounded the shore.

First therefore we enquire whether this Sense do needs haue a *Medium* or no. To speake ingenuously and as I thinke (saith *Placentinus*) it hath no absolute neede, neither shal it be materiall to distinguish betweene an externall and an internall *medium*, becausе we thinke that neither is necessary seeing the Taste which is a kinde of Touch is immediately absolued or perfected as the Touch is. That which we Taste we immediately touch with our Tongues, neither is there Sensation made till the obiect light vpon the Organe. If any man shall imagine that there must be a *Medium*, I aske the question what he will assigne? One of the foure Elements? Or some body compounded of them? Surely neyther this nor that. For if it be an Element it must be Fire, or Aire, or Water, or Earth. But not Fire, for that is hot and dry, which would not conserue but consume the moisture where in especially the obiect of Taste is seated. Now the office of a *medium* is to conserue the Obiect not to destroy it.

The taste needeth no *medium*

No Element can bee the *Medium*.

Not Fire

Add heereto, that the efficient cause of Sapours is heate, but one and the same cannot be the efficient cause and *Medium* of the same thing. Againe, if Fire were the *Medium* we might like a Salamander liue in the Fire or champe burning coales and not bee hurt.

The Aire is not fit for this function, for the Sapor recideth in the mixt bodie out of which it neuer yssueth, wherefore the *Medium* that must leade the Sapor vnto the Organ must also transport vnto the organ the mixt body wherein the Sapor is, but the Aire being a simple and liquid Element is not fit to carry a solid matter.

Not Ayre

The VVater cannot be the *Medium*, becausе we do not liue in it, and therefore it is not contiguous with the Obiect and the Organ.

Not Water.

Much lesse the Earth, for that is cold and dry, both which qualities are contrarie vnto Sapors, and therefore will rather vtterly destroy them then conserue and maintain them.

Not Earth.

One word might haue serued all, There are no pure or simple Elements, & that which is not cannot be a *Medium*? Is it any compound body? No, for a compound body would disturbe and hinder the Taste. Beside, euery mixt body if it haue neuer so little humi-

There are no pure elements

in it is of it selfe gustable, that is, the obiect not the medium of Tast. We conclude therefore that tast is made without any outward medium. Yet we doe not say that Tast is made without any intermediate Body adioyning or growing to the organ of Taste. For as in touching we haue already said in the second Booke that the scarf skin was made by nature to come betweene the obiect and the skin it selfe which was the organ, not to be a medium for that office it doth not performe, but a little to dull the quality of the obiect; so likewise in Tast which we haue often said is a kind of Touching we holde that the membrance which inuesteth the tongue doth performe the same office to the organ, which therefore we may say is as it were a medium, though indeed and in truth it be not so. What kind of medium is necessary.

QVEST. LXII. *Of the organ of Tasting.*

HAuing thus said what we could for this present concerning the medium of Tasting, we now come vnto the organ. Concerning which there is no doubt made, all men herein beleeuing their sense that the tongue is it which discerneth the differences of Sapors. For not onely reasonable but all vnreasonable creatures, when they would taste any thing, doe lay it to their tongues: or if they cannot doe so they lay their tongues vnto it to distinguish the tast thereof. Some haue thought that the pallet is the instrument of this sense, which wee find false, because those men whose pallets are eaten out with the French disease, doe yet taste their meate well enough. It must therefore be the tongue though I am not ignorant that some haue attributed this faculty to the teeth, whose arguments happily we may answer in another place, if in the meane time we shall not thinke them vnworthy our resolution. That the palate is not the organ of Tasting. Nor the teeth.

But there are some who haue conceiued with better reason that the membrane which inuesteth the tongue is the true organ of Tasting: Among whom is *Valesius* in the foure and twentith Chapter of the second booke of his controuersies. But he affirmes it onely confirmes it not, yet because so worthy a schollar hath affirmed it, we will endeauour to make the contrary appeare. Nor the membrane of the Tongue. *Valesius* refuted.

First therefore the temperament which is common to it which other membrances doth denie it this priuiledge, for it is cold and drie, both which qualities are contrary vnto Sapors. Now the qualities of the organ must not be at daggers drawing with the qualities of the obiect, but rather friends, and liue neighbourly together, so as the organ may be potentially that which the obiect is indeed and act. The first argument.

Againe, the same membrane which incompasseth the tongue, doth also inuest the nostrills, the pallet and gullet. If therefore the membrane were the organ, this sense should be made in all these parts, which we find by experience not to be so. *Valesius* very maduisedly resolueth that this very membrane incompassing the nostrills is the organ of smelling, and saith, that it is the diuersity of the temperament which maketh it in the tongue the organ of the tasting and in the nose the organ of smelling. But he is fowlly deceiued, for suppose it had in these places a different temperature, we must not thinke that onely the temper is sufficient to distinguish the organs of senses; But beside to diuers actions there is required a diuers substance; diuerse I say, and such as is not else where to be found. Now this membrane although the temper doe somewhat differ in seuerall places, yet in qualities and substance it is like it selfe appearing so, both to the sight and to the touch. The second argument.

Finally that is the principall part of the instrument into which a soft nerue doth determine, but into this coate no man will say the nerue doth determine who hath but touched Anotomy with his vpper lip, yet *Galen* in the second Chap. of his 16. booke *de vsu partium* seemeth to affirme the same in these words. *As the hard nerues are inserted into the muskles, so are the soft into their proper Organ, as into the membrane of the tongue.* So that hence it might seem to follow that his membran is the proper instrument of Tasting. But this place of *Galen* is no whit against our opinion. For we thinke and confesse that that into which the nerue determines is the true organ. But *Galen* doth not say the nerue determines in the membrane, or coate of the tongue, he saith it is inserted into it; whence we may rather gather yea therefrom it is conuinced that the substance of the tongue is the organ we treat of, because into it the nerues do determine: for being inserted into the mebarne the extremity therof reacheth vnto the substance of the tongue to defer and confer the faculty thereunto. The third argument. Obiection out of Galen. Galen expounded. Obiection. Answer.

But it will be obiected that if this coate or membrane be ill affected the Tast is therewithall depraued. VVee yeeld it to be true, yet not because the Taste is perfected in that

part, but becauſe this membrane concurreth to the action of Senſation, without which in deed we cannot Taſte; ſo in the eye, if the Horny membrane bee violated the ſight is then depraued: and yet it doeth not follow that the Horny membrane is the chiefe Organ of Sight. And thus we muſt vnderſtand *Galen* in the ſecond Chapter of his 4. Booke *de locis affectis*, where he ſayth that the Taſte is vitiated if the membrane of the Tongue be diſtempered. Or we may ſay that this membrane is as it were the *Taſter* to the *Taſte*, which office it hath partly from his own proper temperament, partly from the ſoft nerues which are inſerted therinto, vnleſſe you will ſay that theſe nerues were allowed to the membrane by Nature to giue it an exquiſite ſenſe of Touching, whereof the Tongue ſtood in neede for the defence of his ſubſtance, which aſſertion will not be againſt reaſon.

Galen expounded.

VVe conclude therefore that the membrane of the Tongue hath an exact Senſe of Touching, nor altogether deuoyde of Taſting, not that it taſteth at all of it ſelfe but being contiguous, yea continuall and growing to the ſubſtance of the Tongue, it concurreth withall to the perfection of the action, ſo as without it the Senſe of Taſting cannot be perfected nor accompliſhed.

The concluſion.

Notwithſtanding, we finde another principall part to which, as this membrane, ſo all the other adiacent parts are ſubſtituted by Nature as helpers and handmaides, and that is the proper and ſpongy fleſh or pulpe of the Tongue. For beſide that, it hath a ſubſtance ſuch as you can no where finde the like in the whole body, the Temperament alſo therof is apt and to entertaine and receiue Sapours; for it is moyſt and hot neare of kinne vnto the Nature of a Sapour, that it might more eaſily bee altered thereby. And indeede for the making of this Senſation, it is neceſſary that the Organ ſhould put on the nature of the obiect which *Ariſtotle* meaneth, when he ſayth that the Organ muſt potentially be the ſame thing which the obiect is actually, that ſo it might be altered & actually receiue the nature of the obiect; for how ſhall it iudge of the obiect vnleſſe it doe put on the qualities thereof.

That the body of the roung is the true organ.

Arguments.

Adde hereto that it hath an ingenite humidity, that thoſe obiects which are potentially moyſte, as Salt is, being by this organ actually made moyſt might become ſapide, that freely and frankly exhibite his Sapours.

Againe, what greater argument can there bee, that this fleſh ſhould bee the organ of Taſting then becauſe it is ſpongy, for Taſte is neuer made vnleſſe the moyſture that carrieth the Sapour bee imbibed by the organ of Taſting, to which purpoſe nothing is ſo fit as the ſpongy pulpe of the Tongue. Moreouer, all the other Senſes are double, and therefore Nature, though ſhe had great reaſon to make the Tongue ſingle for the commodity of the voyce, and ſuch other circumſtances as wee haue particularized in our Hiſtory: yet that it might be after a ſort double, ſhe hath drawne a line through the middeſt whereby it is diuided into a right ſide and a left. On that manner there is no part in the mouth diuided, but in the mouth is the Senſe of Taſte, and therefore it muſt belong onely to the Toung.

QVEST. LXIII. *Whether the Tongue alone do Taſte.*

That it may be communicated.

VVEe hauce prooued that the Fleſh or Pulp of the Tongue is the true inſtrument of Taſting. Notwithſtanding it is doubted whether this Action belong onely to this part or may alſo be communicated vnto others. That it may be communicated to other parts: ſome arguments are vrged. Firſt, the Taſte is a kinde of Touching, but Touching is diffuſed thorough all the body. It may ſeeme therefore that the Taſte is alſo diffuſed thorough more parts then one, eſpecially ſo farre as the meate doeth attayne, that is, into the Mouth, the Gullet and Stomacke.

Againe, there yſſueth out of the Braine a ſoft nerue which is ſimple and ſingle in his originall, but when it hath paced a little forward, from the skull it is diuided into two branches: whereof one is inſerted into the Tongue, the other into the lower parts.

Thirdly, we ſee that the Stomacke doeth reiect and caſt vp ſome meates by vomit, other it embraceth and contayneth.

In like manner the Gullet ſwallowes ſome meates well and freely, others not without loathing and much difficulty, yea ſome meates becauſe of the enmity betwixt the ſtomack and their Taſte, euen after they are downe are caſt vp againe.

It may therefore be demaunded how this choyce can bee made, this loathing or liking ſtirred vp, vnleſſe we ſay that the Stomacke and the Gullet do Taſt and diſtinguiſh the differences of Sapors.

Adde

Add hereto the authority of *Ariſtotle*, who in the 11 chapter of his fourth Booke *De partibus animalium* ſaith, that Fiſhes in their ſwallowing do take pleaſure and haue a ſenſe of the meate that paſſeth into their Mawes. Without doubt theſe arguments are not to be contemned, and yet we will make anſwere vnto them.

To the firſt we ſay, that though the Taſte be a kinde of Touch, yet it is not neceſſary that it ſhould in all conditions anſwere or be proportionable to the Touch. Anſwer to the firſt.

To the ſecond, that although the Nerue which is inſerted into the tongue do tranſmit another branch to the Gullet and the Stomacke, yet it doth not follow that the gullet and the ſtomacke muſt taſte, for the ſoft nerues do tranſport the faculty of ſenſation; yet that the Eye ſees colours, the Eare heares ſounds, the Noſe perceiues odours or ſauours, is not by reaſon of the Nerue, but becauſe of the diſpoſition and temperament of the organs. For the faculty of ſenſation is euery where one and the ſame, neither is there any difference in the faculty whereby wee heare, nor in the faculty whereby wee ſmell, from the faculty whereby wee taſte; but all the difference ariſeth from the diſpoſition of the organ. The Foote would ſee, and the Elbow would heare, and the ſides would ſmel, and the crowne would Taſt, if in theſe parts there wer a diſpoſition to receiue the obiects of theſe Senſes. To the ſecond. The differences of the ſenſes depend on the diuerſitie of the organs.

In like manner, although the Gullet and the Stomack do receiue a ſoft Nerue, yet the Gullet and the Stomacke do not Taſte becauſe they are not diſpoſed thereto. But the Reaſon why Nature hath giuen them this ſoft Nerue wee may finde in *Galens* 2 chapter of his 16. Booke *de vſu partium*, to wit, becauſe they ſtood in neede of an exactneſſe of ſenſation. Now (ſaith *Galen*) thoſe parts which had need of exact Senſe, haue all of them receyued ſoft Nerues.

From this that hath bene ſaide, we may ſhape anſwers vnto the reſt of the arguments. That the Gullet ſwallowes ſome meates, and loaths others: that the Stomacke reteines ſome meates and caſts vp others, wee aſcribe vnto the pleaſure or paine which they feele from the tactile qualities: for of the parts of the body of man none hath the Senſe of touching ſo exquiſite as the Stomacke. For beſide that it is membranous it hath an infinite number of branches of Nerues inſerted thereinto, that it is no wonder if it kicke againſt the leaſt offence. So if we thruſt our fingers into our throats wee can procure a Vomit, not that wee make our Stomacke loath any thing, but becauſe the Tactile qualities doe vrge and prouoke a ſenſible part. VVee alſo may ſay, that becauſe of the contiguity of parts the Stomacke is fore-warned by the Tongue; ſo that the Tongue perceiuing anie horrid or vnpleaſant ſauour communicateth the Senſation to the ſtomacke, forewarning it of an approaching enemy which thereupon ſtirring vp it ſelfe as it were to battell, yerleth againſt it and caſteth it forth. And to ſay true, there is ſuch an inſtinct in Nature bred and ſetled in thoſe parts. For wee may not attribute the ſenſe of Taſting to the Gullet or Stomacke, becauſe if theſe partes had Taſte, the ſicke man that takes a pill or Bole wrapt vp in Sugar wuold neuer retaine it, which if he take without Sugar hee preſently caſts vp again: and the reaſon is, becauſe when they are not rowled in Sugar or otherwiſe made ſweete, their bitter or vnpleaſant Sapor is perceyued by the Tongue, & warning thereof giuen to the Stomacke. They are reteyned being ſweetened becauſe that ill Taſte is obſcured and ſo the Tongue deceyued. Being now arriued into the Gullet or the Stomack, although the Sugar melt from them yet they are not caſt vp againe, becauſe the ſtomack doth not perceiue their Sapor. And this is the reaſon why when we would let down any vnſauoury thing into the ſtomacke we endeuour not to touch the Tongue more then of neceſsity, leaſt it ſhould be prouoked thereby. VVee conclude therefore, that neyther the Gullet nor the Stomacke do perceyue Taſts or Sapors but onely the Tongue. To the third. Why the ſtomack caſts vp ſome meat & reteins other. Another anſwere to the argument. Of the ſwallowing of Pils

QVEST. LXIII. *In what part of the Tongue the Taſte is moſt exacte.*

HAuing found out the Organe of Taſting, it remaineth in the laſt place to ſearch in what part of the Tongue the ſenſe is moſt exacte, for there is no queſtion but there is a great difference. That the back part taſteth beſt.

There are ſome reaſons to perſwade vs that the backpart of the toung doth taſte better then the forepart. Firſt, becauſe at the back-part of the Tongue the Almonds are ſeated on either ſide which doe receiue the ſpittle and a great quantity of moyſture: wherefore becauſe the ſpittle doth helpe this ſenſe very much, it is

to be imagined that where there is moſt ſpittle there is beſt Taſting. Againe, the Nerues which are inſerted into the backſide of the Tongue are greater then thoſe which are inſerted into the foreſide. Yet *Ariſtotle* holdeth the contrary and prooues his part better, for what can be more certaine then experience.

The contrarie opinion. *Ariſtotle.* Reaſons

If therefore we deſire to Taſte any thing more curiouſly we apply it to the tip of our tongues, and if it fall toward the roote we call it backe againe. Againe, when wee are to ſwallow any thing whoſe taſte is diſpleaſing to vs we haſten it to the roots of our tongue as ſoone as we can. The reaſon is, becauſe the ſenſe of Taſting is not there ſo exquiſite. Moreouer, it is very reaſonable that the Taſte ſhould be more perfect in the fore-part, becauſe this ſenſe was allowed to the creature to diſcerne hurtfull Taſts and to auoid them. But if the perfection of the Taſte had beene at the rootes, that which is offenſiue might haue ſlipped downe before we were aware, whereas the tippe of the Tongue diſcerning the difference beſt, is alſo beſt able to free it ſelfe from that wherewith it is offended. Add heereto, that the forepart of the Tongue is ſofter, more ſpongie and better diſpoſed to imbibe the humidity wherein the Sapor is conteined.

VVe conclude therefore, that the perfection of the Taſte is not in the rootes but in the tip of the Tongue.

Anſwer to the former arguments.

The arguments that were brought to prooue the contrary may eaſily bee anſwered. For becauſe there is ſo great a plenty of moiſture at the roots of the Tongue, therfore the beſt Taſte ſhould not be there: for ſuperfluous humidity doth not quicken the Taſte but dulles it.

Neither do we deny but that the Nerue is larger at the roote of the Tongue, but it doth not follow that therefore the Taſte is there more perfect, becauſe in the fore-part though the Nerues be leſſe, yet they be more plentifull and aboundant, and therefore do cauſe the Taſte to be more perfect.

And thus we are come vnto an end of theſe Labyrinths concerning the Senſes, wherein we haue beene ſomewhat the more prolixe, that thoſe which loue the contemplatiue part of Philoſophy might haue ſomething wherewith to pleaſe their appetites. It is true indeede that there are many paſſages in theſe Controuerſies, which for the moſt part we haue taken out of *Iulius Caſſerius Placentinus* which might wel haue befitted the Schooles themſelues, but wee imagine that theſe our Labours may happily fall into ſome mens hands who will be willing to recognize thoſe Studies which for better employments they haue intermitted. A very few of which kinde if I ſhall giue contentment vnto, I will not thinke my labour ill beſtowed. Other men vvho do not vnderſtand them, or elſe are better able then my ſelfe to ſatisfie themſelues, may turne ouer to that vvhich ſhall be more fitting for their Diſpoſitions. And ſo we will leaue the Head and Senſes, and come vnto the Ioynts.

The End of the Eight Booke of the Senſes, and the *Controuerſies thereunto belonging.*

THE NINTH BOOKE,

Wherein the Ioyntes are briefely *Deſcribed.*

The Præface.

IN the whole body of Man there is nothing more wonderfull then the ſtructure and poſition of the Ioynts, nor any thing wherein a man doth ſo much differ from all other creatures. The bowels are moſt what a like in all, both for Nutrition, Generation Life and Senſe, becauſe all creatures haue like vſe of all thoſe parts as well reaſonable as vnreaſonable. The onely thing which makes the difference is the Reaſonable Soule which is inuiſible, a Nature tranſcendent and aboue the Nature of the body. But the faſhion and poſition of the Ioynts whereby the body is liſted vp from the earth, vppon which the other creatures doe grouell, maketh the greateſt difference betweene man and beaſt. It were a world of wonder to enter into diſcourſe of the particular Reaſons of this poſition, and wee haue partly handled them before in the firſt Booke, but eſpecially wee purpoſe to proſecute them in this ninth Booke deſtined to that purpoſe.

Galen hath taken eſpeciall paines in this argument appropriating therunto his three firſt Bookes *de vſu partium*, wherein he hath preuented any man that ſh ould take paines after him. Wee ſhall thinke wee haue quit our ſelues well if we can in ſome ſort abbreuiate thoſe large Volumes in this place, wherein we haue laboured ſo much the more to be as conciſe as the ſubiect matter will giue vs leaue, becauſe all the particulars will fall vnder our diſcourſe in our bookes of the Muſcles the Veſſels and the Bones. The Reader therefore is to be intreated to content himſelfe with this bare ouerture, where in wee will but muſter the parts cloſe together, becauſe we ſhall haue time and ſcope to draw out our troopes and to marſhiall them in better order when we come into the large fields of the Bookes which follow.

CHAP.

CHAP. I. *A breefe deſcription of the Ioynts.*

WEe before deuided the body of Man into three Regions or Venters, and the outward parts or the Ioynts. Through the three Regions, Naturall, Vitall & Animal, we haue carried our Story with as great breuity and perſpicuity as we could, it followeth now that we proſecute our Hiſtory vnto the Limmes. The Ioints therfore which grow vnto the body as boughes vnto the trunke of the tree are called in Greeke κῶλα and γύα, in Latine *artus ab artando*, in Engliſh wee will call them Limmes or Ioynts, becauſe there are moſt ioynts in them.

2 kinds of ioynts.

There are therefore two kinds of Ioynts, the vpper and the lower; the vpper ioyntes are called by the common name of the *Hand*, for the Ancients accoũted the whole member from the ſhoulder to the fingers ends to bee all the *Hand*. The lower Ioynts as likewiſe called *Pedes*, that is, the Feete, of which we ſhall ſpeake afterward. The whole Hand *Hippocrates* and *Galen* doe deuide into three parts in *Brachium*, *Cubitum*, and *ſummã* or *extremã manum*, that is, the Arme, the Cubit and the Hand as we call it.

The diuiſion of the hand

The arme.

The Arme *Celſus* calleth *humerus*, *Feſtus* calleth it *Armus*, whence our word came. The Head which is inſerted into the broade bone or blade of the ſhoulder is called by *Pollux* ἀκρωμία, by *Euripides* ὦμος, the end is called ἀκρωλίνιον.

The cauity vnder the ioynt of the ſhoulder *Ariſtotle* calleth *axilla*, commonly *ala*, becauſe in it do grow hayres as feathers in a wing which is called *ala*, and we call it the armehole.

The Cubite

The ſecond or middle part is called in Greeke πῆχυς or ἀγκών, in Latine *Cubitus* or *Ulna*, we will call it the Cubite to diſtinguiſh it from the vpper part which we call the Arme.

The hand.

The third part is called *Manus*, from *manare* to flow, becauſe it floweth as it were out of the Cubit: this we call properly the Hand, and it hath three parts, the wreſt called *brachiale*, the After-wreſt called *poſt-brachiale*, and the fingers called *digiti*, of which wee ſhall ſpeake in their due place. And this is the common diuiſion of this ioynt. VVee now will follow the particular parts of the diuiſion.

CHAP. II. *Of the parts of this Ioynt in generall.*

THE proper parts of the whole Hand taking it in the large acception of the Ancients, are beſide the common parts which we pretermit, the Veſſels, the Muſcles and the Bones. By the Veſſels I vnderſtand the Veines, the Arteries and the Nerues. The Veines which are deriued through this whole member doe ariſe all from the Axillary branch: and there are two; the firſt paſſeth along on the inſide, the other on the out ſide of the arme. That on the inſide is called *Baſilica*, that on the out ſide is called *Cephalica*. The *Baſilica Hippocrates* calleth *Venam internam* the inward veine, Others call it *Hepatica* & *Iecoraria*, that is, the Liuer-veine. And it is ordinarily deuided into a deeper and a ſhallower. The deeper climing ouer the axillary Artery and the third paire of ſinnewes paſſeth along to the bought of the Arme which we commonly call the Elbow, and ſo beſtoweth his branches vpon both the bones of the Cubite.

The veines of the whole hand.

Baſilica.

The Liuer veine.

Mediana.

The ſhallower runneth vnder the skinne to the ioyning of the Cubite with the Arme where it is clouen into two boughes, one of which paſſeth to the inſide of the Cubite, and there is vnited with a branch of the humerary veine, and from that coniunction ariſeth the *Common veine* which they commonly call *Mediana* or the middle veine; the Arabians cal it the *blacke veine*. The other bough deſcendeth along the lower ſide of the Cubite ſprinkling the skinne and partes by which it paſſeth with diuers ſmall branches.

The blacke veine.

Cephalica or the head vein

The *Cephalica* or Head-veine ſo called, becauſe it is opened in diſeaſes of the Head; *Hippocrates* calleth *externa* or the outward veine, becauſe it creepeth along the outſide of the arme: others call it *Humeraria*, (becauſe it paſſeth thorough the ſhoulder betwixt the Muſcle called *Deltoides* & the Tẽdon or chord of the Pectoral muſcle) which falling down vnder the ſurface of the skin, when it commeth vnto the bought of the Cubite is diuided into two branches: the one borne along obliquely into the inſide of the Cubite coupleth it ſelfe with the braunch of the Liuer-veine, and betwixt them beget the common or middle veine; the other which is larger deſcendeth by the *Radius* almoſt to the middeſt thereof

of and hence running oblikely to the wriſt, it watereth almoſt all the backe of the hand, and endeth in a notable and manifeſt branch, betwixt the little and the ring fingers: where it is called *ſalua tella*, and is opened, as authors ſay, with good ſucceſſe in ſplenitick perſons. *Salua tella.*

The arteries which belong to this hand doe proceede in one bough from the axillary artery, and this bough is called *Baſilica*. It hath two branches one ſetled deepely, the other eminent betweene the skin and the fleſh. Both of them doe affoord many deriuations out of themſelues, but that of the ſhallower is moſt notable which is often times to be ſeene in the inſide of the wriſt a little aboue the roote of the thumbe, at which place and by which artery we vſe to feele the pulſe to find out the differences thereof. The arteries of the hand. The pulſe.

And for ſinewes there areſix paire diſſeminated through the whole hand, the firſt commeth out of the firſt racke bone of the necke and is ſpent in the Deltoides muskle and the skin neere vnto it. The ſecond ariſing from the ſixt racke bone of the necke firſt paſſeth into the double headed muskle; then it caſteth of a ſmall branch to the long muskle of the Cubit, and at length when it attaineth to the elbow it is diuided into branches The third being mingled with the ſecond, reacheth his helpe to the muskle of the arme, which lieth vnder that with a double head. The fourth which is the largeſt of all the reſt falling vnto the ſame muskle together with the deepe liuer-vaine and the inward artery is deuided into diuers branches The fift paſſeth along betwixt the muskles, which bend and extend the cubit and hauing gotten ouer behind the inward proceſſe of the arme, and being mixed with the third coniugatiõ, is conſumed in the fingers, giuing to the little finger two nerues, to the ring finger likewiſe two and to the middle finger one. The ſixt paire ſliding downe betweene the skin & the neruous membrane by the inward proceſſe of the arme determineth into the skin of the Cubit And theſe are the veſſels of the whole hand whoſe deſcription we ſhall more exactly ſet downe in a fitter place hereafter. Six paire of ſinewes of the hand. The firſt. The ſecond. The third. The fourth. The fift. The ſixt.

The muſcles of the hand. The bones of the hand.

The muskles of the whole hand are very many, ſome moue the Arme, ſome the Cubit ſome the Radius, ſome the wriſt and ſome the fingers, of which alſo we ſhall ſpeake in their proper place. The bones of the hand are diuers, the arme hath one bone, the *cubite* two, the *wriſt* eight, the *after-wreſt* fower, the fingers fifteene, to which we may adde if we pleaſe the ſmall ſeede bones called *Seſamoidea* all which we will as curiouſly and accurately as we are able deſcribe in our booke of the bones, whether at this time we refer the reader.

CHAP. III. *Of the excellency of the hands.*

MAn, who is the crowne and pride of Nature, that bold and confident worke-Miſtriſſe, him I ſay, God on his birth day, did caſt out vpon the duſt of the earth, naked, vnarmed, and weltring in his bloud, to enioy or rather to deplore an inheritance of ſorrow and miſery. Yet notwithſtanding becauſe he is ſent into the world to be a combatant and not a ſluggard, he hath armed him with two wondrous weapons, which he hath denied to all other liuing creatures, Reaſon and the Hand. His reaſon is the ſtoreholſe of all arts and ſciences, the firſt grounde-worke and foundation of whatſoeuer the immortall ſoule is naturally capeable or apprehenſiue of; an arte it is, as before all arts, ſo hath it all arts for his ſubiect or matter whereabout it is occupied. The hand is an inſtrument, but as it is the firſt inſtrument ſo it is the framer, yea and imployer of all other inſtruments. For not being framed for any one particular vſe it was capeable of all; ſo as it may iuſtly be compared to the ſoule, which as the Philoſopher ſaith, is, though not in deed yet in power and ability all things. By the helpe of the hand Lawes are written, Temples built for the ſeruice of the maker, Ships, houſes, inſtruments, and all kind of weapons are formed. I liſt not to ſtand vpon the nice skill of painting, drawing, caruing, and ſuch like right noble Artes, whereby many of the Ancients haue made their names honorable vnto vs, yea and eternized them to the worlds end. By our hands we promiſe, we call, we diſmiſſe, we threaten, we intreate, we abhorre, we feare, yea and by our hands we can aske a queſtion. By the helpe of the hand although a man be borne vnarmed, yet is he able to ſafegard himſelfe from all other creatures: and all thoſe creatures which come ſtrong and armed at point into the world, how fierce ſoeuer they be, how able to abide the violence of heauen it ſelfe, yet are they not ſafe from the hands of men. For doth not the induſtry of mens hands preuaile againſt the hornes of the Bull, the teeth of the Lyon, and the paw of the Beare, yea whatſoeuer is comprehended vnder the cope of heauen, by the skill of the hand is brought vnder our ſubiection and made tributary vnto vs. Man is the glory of Natures workemanſhip. The weapons which man hath more then other creatures. What a man can doe with his hand.

And

Anaxagoras. And therefore *Anaxagoras* as *Plutarch* reporteth, marking diligently the curious fabrick of the hands, the postures of the fingers, as they moue either together or apart, the mighty strength, the cleane nimbleneſſe and the ſoft delicacy thereof, aſcribed vnto them the cauſe and originall of mans wiſedome. How much wiſer was *Galen* who in thoſe melodious Hymnes which he wrote to the praiſe of his Creator, I meane his Bookes of the Vſe of Parts diſcourſing very curiouſly concerning this curious inſtrument concludeth, That man is not therefore the wiſeſt of all creatures becauſe he hath Hands, but becauſe hee is the wiſeſt of all creatures, therfore Nature furniſhed him with this excellent inſtrument. *Galen.*

The Handes conſecrated to Faith. It was not the Hand that taught men Arts but Reaſon, yet the ſeruant and miniſter of this reaſon and wiſedome is the Hand: they are the Vicars or Subſtitutes and Suffraganes of the ſpeech, the interpreters of the ſecret Language of our ſilent conceits, ſignifying to all men in a few Letters as it were by Hieroglyphicks what the very thoughts of our Hearts are.

Numa Pompilius conſecrated the Hands to *Faith*, and therefore all Compacts, Couenants, Truces & enter-courſes whatſoeuer are held inuiolably ratified by the very touch of the Hand, and at this day in our neighbor-countries the Principall Nobility do ſweare their allegiance into the Handes of their Prince or his Subſtitute.

That very Touch was alſo among the *Perſians*, the moſt ſacred pledge of fidelity: and therefore the moſt Ancient did vſe to ſalute one another on this manner, giuing and receyuing honor by this part. Likewiſe they which adore Princes or great Potentates are accuſtomed to kiſſe their Hand and incline their head. In the Egyptian Hieroglyphicks the Hand was the Embleme of Fortitude, and therefore they which ſeeke for helpe doe call for the right hand, for ſo it is in our common Prouerbe, *Lend mee your helping Hand.* I liſt not to commend the Hand from that ſuperſtitious Art or Impoſture, rather of ſuch as call themſelues *Chyromantickes*, whoſe idle ſpeculations are not fit to bee mingled with our ſerious diſcourſe, which we will now transferre from the excellency and commendation of ſo curious an Inſtrument to a more Anatomicall conſideration of the Vſe, Figure and Structure of the ſame.

The Hands Emblemes of Fortitude.

The vanity of Chyromātiks.

CHAP. IIII. *Of the Vſe, Figure and Structure of the Hand, properlie ſo called.*

The ſeuerall vſes of the Hand. THE true office of the Hand is to apprehend or to holde, and his proper action is apprehenſion (for *Hand* and *Holde* are Coniugates as we term them in Schooles) from whence it is called *Organum ἀπτικὸν*. The Firſt vſe therefore of the Hand is to take hold. Another vſe of it is to bee the iudge and diſcerner of the Touch. For albeit this touching vertue or tactiue facultie be diffuſed through the whole body both within and without, as being the foundation of the Animall *Being*, which may be called *Animality*, yet we do more curiouſlie and exquiſitely feele and diſcerne both the firſt and ſecond qualities which ſtrike the Senſe in the Hand then in other parts. It is alſo an Inſtrument well fitted to eaſe our paynes, to propulſe or driue backe iniuries and to defend the fore-parts of the body. Wherefore for theſe vſes and for the performance of all his functions it hath that figure which we ſee, and that admirable ſtructure which as well as we can we ſhall vnfold vnto you.

The hand the inſtrument of touching.

The figure of the Hande. The Figure is long and diuided into many parts that it might comprehend in one all kinde of Figures, the round or Spherick, the right and the hollow, for all figures are made of three lines, a crooked, a hollow, and a ſtraight. Beſide, this figure doth equally apprehend both greater bodies and leſſe; for ſmall things it holdeth with the ends of two fingers, the great finger or the thumbe and the forefinger.

Why diuided. If the body bee a little bigger, it comprehendeth it with the ſame fingers but not with the ends. If it be yet bigger, we vſe three fingers, the thumbe, the fore and the middle fingers. If it be larger then we can comprame with three we vſe foure, and ſo fiue, and at length the whole hand. Now if the Hand had bene made of one continuall peece, it would onelie haue apprehended a body of one magnitude. Neyther was it ſufficient that the Hande ſhould be diuided into fingers, vnleſſe the ſame fingers had beene placed in a diuers order and not in the ſame right line, ſo as one was to be ſet or oppoſed to the other four, which The ſtructure of the Hand. being bowed with a ſmall flection might meete and agree with the action of the other foure oppoſite vnto it. And this is the manner and proportion of the figure. For the ſtructure if it be diligently attended, it will imprint in vs an admiration of the wonderfull skill and

and workemanship of Nature and it is on this manner. Because the Hand was the most noble and perfect organ or instrument of the body: God the Creator moulded it vp of diuers particles, all which for our better vnderstanding we will referre vnto foure kindes. The first kinde is of those which originally and by themselues doe performe an action: the second of those without which an action is not performed: the third of such as do more perfectly accomplish an action; and the last of such particles as do preserue an action.

The first and principall part of the hand is a Muscle, because there is no apprehension without motion; now wee know that a Muscle is the immediate organ of voluntary motion. The principall part of the hand is the muscle.

The second part without which there is no apprehension is a Nerue; for the Muscle moueth not, vnlesse it be commaunded, this commandement the nerue bringeth together with a subtle spirit, and therefore it is called *Later* or the poast.

The third which accomplish the Action are the Bones and the Nayles: the Bones doe make the action strong and stable, without which the Fingers might indeede be extended and bent againe, but because of their softnesse they would euer haue beene trembling, and not able to haue holden any thing straight or firmely. The bones & nailes doe make the action perfect.

The Nayles further apprehension. The particles which do preserue the Action are the Veines, the Arteries, the Skinne and the Fat. The Veines water it with bloud; the Arteries quicken it with vitall spirits; the Skinne and the Fat make a *Colligation* or tying together of all the rest.

CHAP. V. *Wherein is declared the reason of the framing of all the similar parts whereof the Hand is compounded.*

THe Muscle therefore is the principall part of the Hand by which immediatly apprehension is made. But because there are two especiall partes of a Muscle, the Flesh and the Tendon or Chord, Nature placed many Tendons and little Flesh vpon the Fingers, because the end of the Hand should be light & thinne, not heauy and thicke. Why the fingers haue little flesh.

These Tendons from their originall euen to their insertion are round, that they might be lesse subiect to outward affects, but in the very insertion they growe broader that the motion may be more nimble. But because there are many motions of the fingers, to wit, right, as Simple; flection or extention; & oblique when they are brought together or parted asunder; it was necessary that there should be Tendons both without and within and on the sides of the fingers. The tendons of the fingers.

But how many Muscles there bee of the hand, whence euery one of them ariseth and where they are inserted together with their structure, we shall declare in the next Booke, wherein wee handle of sette purpose the Historie of all the Muscles.

Nerues they haue dispersed into their Muscles and Flesh, and those very many from the fourth and fift payre of the Arme which yeelde vnto them the faculties of Sense and Motion. Their nerues.

The Bones of the Hand are eight of the Wrest, foure of the After-wrest which are tyed together with a strict and immouable articulation or iuncture. The Bones of the Fingers are ioyned by *Diarthrosis*, for it behooued that they should so moue as they might be able to apprehend or take hold of all figures or fashions of things. These Bones are onely three neither more nor lesse, for more would haue hindered perfect extention, and fewer would not haue admitted so many and diuers particular figures. And all these that the motion might bee more facile and easie, are knit together by *Ginglymos*. Nowe the variety of the motions is furthered both by the gristle which compasseth their extreamities, and by the fatte and oylie humour which like a slime doth line the ioynts. But because when the creature according to his pleasure shall bend and bow these ioynts, they should not be disseuered or fall out of their seates, Nature hath knitte them together with tyes and bands, and wedged them in also with small bones like *Sesamum* seedes. For these small bones which are in the inner ioynts of the Hand doe not suffer the ioynts to *Luxe* or shoore inward when we streatch out our hands strongly; and those that are placed in the outward ioyntes keepe them from leaping outward when wee bend our handes with violence. Their bones. The ties or bands. The seede bones and their vse.

The further discourse of the Bones of the Hand you shall find hereafter in the last Book which is of the Bones: for to transcribe euery particular here, were to abuse my owne time and your patience.

The

The bones therefore doe make the action more perfect. For if the fingers were without them, we should be able to performe those actions only wherein it behoued vs to draw the fingers into a circular forme. The Nayles also were made to further the vse of the Hand; for hard and small bodies would easily slie from the fingers, vnlesse there had beene set to their ends a hard body, both to strengthen and establish the flesh, as also to keepe in and retaine such small and slipery things. Finally the veines, arteries, skin, and fat, doe preserue or conserue the action.

The vse of the nailes.

CHAP. VI. *Of the distincter parts of the hand, of the Wrest and of the After-wrest.*

THe Hand properly so called, hath three dissimilar parts: the Wrest, the After-wrest, and the Fingers. The Wrest called *Carpus*, the Latines more vsually call *Brachiale*, the Arabians *Raseta* or *Roseta*, because it was a custome to adorne that part with roses, and diuers flowers. It consisteth of eight bones set in two rankes, which haue no proper names belonging vnto them. The After-wrest called by the Latines *post-brachiale* and by *Celsus Palma*, is deuided into two parts, the internall and the externall: the internall part which makes the hand hollow when it is stretched foorth, hath his name in *Hippocrates* from a word which signifieth a stroke, because with the palme we vse to strike. The Latines call it properly *Palma*, and so doe we the Palme of the hand: whichwnen it is crooked & hollowed is called *vola manus*. The outward part which is the backe of the hand is called *manus auersa* or *dorsum manus*. In the Palme of the hand there are many particles obserued. For the beginning of it which riseth a little toward the inside of the wrist is called *Radix manus* the roote of the hand. The middle part is called *Interstitium* or the partition. The fleshy swellings which the Chyromanticks call hyllockes or Monticles do make the brawne or pulpe of the hand and are called properly *Thenar* of a word which signifieth to smite. That hillocke which is vnder the thumbe is called *mons martis*, that vnder the fourth finger, *mons Iouis*, that vnder the middle finger, *Saturni*, that vnder the Ring finger *Solis*, that vnder the little finger is dedicated to *Venus*. The *Thenar* that is the space which is betwixt the thumbe and the fore-finger is called the hill of *Mercurie*: and the *Hypothenar* which is the brawne betweene the roote of the thumbe and the little finger is called the *Moone hill*. Beside these, there are also in the *Vola* or cup of the hand many lynes, by the sight and obseruation whereof, the Chiromantickes doe promise and take vpon them, to foretell the length or shortnesse of the life, good or euill fortune, Naturall inclinations, and in a word the euents of all accidents: with how great reason or from what cause or ground either in Nature or in Diuinity, *ipsi viderint*: we will onely for distinction sake, and because it is rather lookt for at our hands then that we approue any such impostures, name them vnto you. They are said to be fourteene, but three are principall: the first which compasseth in the thumbe is called *Ptasera* the lyne of life by others *temporalis*, or the lyne of Tyme. The second which runnes ouerthwart through the middest of the *Vola* or Cup is stretched to the moone hill, and is called *ikteraria* the Lyuer lyne or the Naturall lyne. The third beginneth from the *Hypothinar* or moone hill, and reacheth to the mount of *Iupiter* and is called the table or bed lyne of *Venus*.

The wrist.

The after-wrist.

The palme.

The backe of the hand.

The hillockes of the hand.

The Lines.

The line of life.

The naturall Line.

The table line or line of Venus.

When the hand is shut it is called *Pugnus*, or the fist; when it is halfe bent it is called *condylus*. Further we must obserue that Nature hath made two hands, one to helpe and assist the other, the right and the left. Some there be which can as well vse this as that, and are called *Ambidextri*. A woman saith *Hipocrates* cannot be an ambidexter, that is she cannot vse both hands alike.

Why two hands.

CHAP. VII. *Of the Fingers of the Hand.*

THe last part of the hand containes the Fingers, called *digiti*, whose order and ranke is called *Phallaux*; the internall articulations or ioynts; are called *internodia*, the knots of the fingers. The fingers ends which are round and fleshy are called *Vuia* or the grapes. The outer part of the fingers haue knubbie or knotty ioynts called in Latine *Nodi*, we call them knuckles, and there are three in euery finger. Each hand hath fiue fingers, neither more nor lesse, that the apprehension might be more perfect. For take away the thumbe, and you take away the power and strength of all the rest: if you take away the little finger you canot incompasse anything circular

The parts of the fingers.

Why fiue fingers and no more.

cularly. Now theſe fingers vvere made vnequall in length and magnitude that wee might the better comprehend all figures and all quantities both greater and leſſe. The firſt, because in ſtrength it is equipolent or equiualent to al the reſt is called *pollex* or the Thumb and hath onely two ioynts. And this finger hath peculiar muſcles, bending, extending and leading it too and fro, becauſe it hath ſomething peculiar in his motions. The ſecond is called *Index* from his vſe, becauſe we vſe it when we would ſhew any thing. *Suetonius* calleth it *Salutaris*, it hath a Greeke name alſo from a word which ſignifieth to licke, becauſe with it we vſe to taſte or licke any thing. The third is called *Medius* or *Famoſus* the middle from his ſituation, *Famoſus* becauſe by ſtretching this finger foorth we vſe to deride or diſgrace when we liſt.

The Thumbe

The forfinger

The middle-finger.

The Ring finger.

The fourth is called *Medicus*, becauſe therewith in old time they vſed to mingle or ſtir medicines; tis alſo called *Annularis* or the ring-finger, becauſe the Ringes are there moſt commonly worne. The fift, becauſe it is the leaſt is called *Minimus*, and *Auricularis* becauſe with it we picke our eares. Euery finger hath three bones ioyned by *Ginglymos*, as we ſhall ſay heereafter. Finally, for more ſteddy apprehenſion there are nailes ſet vnto the Fingers ends engendred of the more craſſe and thicke excrements of the third concoction, and therefore they grow continually only in length as do the haires. But their growth is not by nouriſhment but by an imperfect acruing of the matter, for there is no traction or aſsimulation of aliment, but onely an appoſition of excrement.

The little finger,

The nature of the Nailes.

They are moderately hard that they might not be hurt with outward things ruſhing against them and alſo round for their further ſecurity: the Latines call them *Vngues*, their roote which is like a white moon is called *Radix* or *Ortus*: the tops which we pare off *Extremitas*, the white ſpottes in the Naile *Mendacia*, ſo many ſpots ſo many lyes. And this ſhal ſuffice for the deſcription of the vpper Ioynts, now follow the lower.

The partes of the Nailes.

CHAP. VIII. *Of the Foote in Generall, his Excellencie, Figure, Structure and Vſe.*

AS man alone, becauſe he was the wiſeſt creature had Hands giuen vnto him the firſt and originall Inſtruments of the world, ſo he alone of all creatures which dwell vpon the earth and vſe feete onely, hath two feete anſwereable to his two hands; for if he ſtood groueling on foure ſtiltes, how could hee ride, write, build, throw a weapon, or exerciſe any of thoſe Arts wherewith he is furniſhed. The Figure and poſture of bruite beaſts had beene altogether vnprofitable and incommodious for this diuine creature, for neither could he haue looked vppe to heauen, for which cauſe euen *Anaxagoras* could ſay that he was created; nor ſit him down to meditate, for they ſay, that *the ſitting ſoule is the wiſeſt*, neither could he paſſe through ſharpe vnequall or ſloping places, climbe Turrets, builde houſes, or any ſuch thing. It is true, that the more feete the ſwifter is the creature (other things being equall,) but what neede had man of ſuch footemanſhip to ouertake, when by his induſtry hee is able to circumuent all other creatures? He was therefore made *Bipes* that is, with two feet, & therefore he ſtandeth vpright or ſitteth at his pleaſure.

Why a man hath but two feete.

The proper vſe of the foote is to walke and the action is walking, and therefore the ſhoot is called *Inſtrumentum ambulatorium* or a walking Inſtrument. This walking is vvhen one Legge reſteth vpon the ground, and the other is brought about forward. The reſting is the action of the foote properly ſo called: the reach forwarde the action of the legge: and therefore ſeeing ambulation is made by ſtation and motion, that is, ſtanding & proceeding, the foote it ſelfe is the inſtrument of the former, and the whole legge of the latter.

The Office of the Foote.

How ambulation is made.

Now for aſſured and conſtant or firme ſtation, as alſo for the accompliſhment of thoſe many motions whereof we ſtand in neede, the ſtructure and figure of the foot and legge is ſuch as we ſee. For it is diuided into diuers ioynts, and the toes are made long & broad not ſo long as in the Hands, but only as was neceſſary to faſten the feete when we would ſtriue to run. For if the Toes be preſſed vnto the ground, it is ſtraunge with howe much ſtrength and ſecurity the body is driuen forward.

The figure of the Foote.

Moreouer, the feete were made hollow in the midſt that they might better paſſe thorough all places: for the hollow ſoal encompaſſeth that which is round or gibbous whereon we tread, and the Toes do hold vs faſt in right, oblique, ſloping and aſcending progreſsions. There is a great ſimilitude betwixt the feete and the hands, ſo as wee haue ſeene ſome who had no hands, to do all the offices of the hands with the feete.

The likeneſſe betwixte the Feet and the Hands.

CHAP. IX. *The ſimiler parts of the Foote in the large acception.*

ALl that by the ancients is called the Foote which reacheth from the hip ioynt euen to the end of the Toes. It may be diuided into ſimilar and diſſimilar parts. The ſimilar parts as in the hand ſo here are containing or contained; containing, as the ſcarfe-skin, the true skin, the fat, and the fleſhy membrane. The parts contained are the veſſells, the fleſh and the bones. The veſſels are of three ſorts, veines, arteries, and ſinewes. The vaines doe all deriue their pedegree from the Crurall branch. This crurall branch ſhooteth out of himſelfe many ſprayes through the thigh, the leg and the feete, deuided into many twigs. Six of them are among the reſt moſt conſpicuous and are called by theſe names. *Saphena*, *Iſchias minor*, *Muſcula*, *Poplitea*, *Suralis*, and *Iſchia maior*. The *Saphena* or anckle vaine ariſing from the kernells in the groine paſſeth downe on the inſide of the thigh betwixt the skin and the fleſhy membrane, and reacheth ouer to the outward anckle and is after diuerſly conſumed or ſpent into the skin of the top of the foote. The leſſer *Iſchias* oppoſite to the *Saphena* is diſtributed into the fore skinne of the hippe and the muſcles of that part. The *muſcula* is diuided into two branches, the leſſe of which watereth the muſcles which extend or ſtretch foorth the legs. The greater lies deepe in the fleſh, and is diuerſified almoſt into all the muſcles of the thigh.

The ſimilar parts of the foote.
The veines of the foote.
Saphena.
The leſſer Iſchias
Muſcula.

The *Poplitea* is made of two branches of the crurall vaine ioyning together, and after it hath ſent ſome ſmall ſciences into the backe skin of the thigh, it falleth downe through the middeſt of the ham, and is ſometimes ſpent into the skin of the calfe, ſometime it paſſeth to the very heele, and ſometime turneth aſide vnto the outward anckle.

The Poplitea

The Surall vaine is diſſeminated into the muſcles of the *Sura* or calfe, and vnto the skin which is on the inſide of the leg: and being reflected about the inner anckle, it attaineth vnto the inſide of the foote, and the skin of the great toe, very rarely to any of the other toes.

The Surall

The greater *Iſchias* hath two parts, one greater which paſſing through the muſcles of the calfe ſpendeth it ſelfe into ten ſhoots allowing two to each toe. The leſſer which endeth betwixt the Perone and the heele ſometimes preforating the ligament in the middeſt is diſperſed into the muſcle which draweth the toe backward and into the skin.

The greater Iſchias,

The crurall artery brancheth it ſelfe like the vaine, ſo that euery vaine hath an artery accompanying it. The nerues which are diſſeminated through the whole leg are fowre and thoſe very notable, which ariſe from the three lower paires of the loynes, and from the fowre vpper of the holy or great bone. The firſt and the vppermoſt falling vnder the Peretoneum to the little Trochanter is conſumed into the muſcles of the thigh, and into the skin, both on the out and on the inſide, before it touch the knee. The ſecond and the lower, deſcendeth through the lesk together with the crural veine and artery into the thigh, and ſendeth a notable branch to accompany the anckle vaine through the inſide of the thigh, euen vnto the foot, in the meane time beſtowing ſmall tendrills vpon the neighbor skin: but the greater part of it together with the vaine and artery is diſperſed into the inner muſcles of the thigh. The third lower then the former diſperſeth his fauours to the muſcles of the yard, and to ſome of the muſcles alſo of the thigh, not forgetting the skin of the lesk, and afterward it determineth in the neighbour muſcles aboue the middle of the thigh. The fourth which is the thickeſt, drieſt and ſtrongeſt of all the nerues hauing his originall from the fowre vpper ſpondells of the *Os ſacrum* or the holy bone, gliding along betwixt it and the hanche bone, affordeth certaine branches vnto the neighbor parts, as vnto the skin of the buttockes and of the thighe, and to the muſcles contained vnder them. Afterward departing into two branches, the leſſer falleth by the *Perone* and giueth two ſhootes vnto each toe, the greater ſtretching along the leg and the foote, giueth likewiſe two branches to each toe, but both theſe boughs by the way as they paſſe doe touch at the heads of the muſcles and at the skin of the leg and the foote, and doe tye them together. And this ſhall ſerue for a ſhort deſcription of the veſſells.

The arteries of the foote.
The 4 nerues of the whole foote.

The muſcles of the feete.
The bones of the feete.

The muſcles of the feete are diuerſe ſome Bend the thigh, Extend it, bring it to the body lead it from the body and turne it about: others doe moue the leg with the ſelfe ſame kinds of motions, others bend and extend the foote it ſelfe. Finally, there are others, which moue the toes of the feete, the particular hiſtory of all which you may require in the next booke of the muſcles. The bones of the feete are very many: one of the thigh, two of the

leg,

legge called *perone* and *Tibia*, togeather with the whirle-bone of the Knee: the wreſt of the feete called *pedium* hath ſeauen bones: the after-wreſt called *Metapedium* hath fiue, and there be 14 of the Toes to which may be added ſeed-bones like to thoſe which we found in the hand. Of all which we will giue you ſatisfaction in our Booke of the Bones.

CHAP. X. *An explication of the diſsimilar parts of the whole foote.*

THE great foote is diuided as the hand into three diſsimilar parts, the *Femur* or Thigh, the *Tibia* or Legge, and the *pes* or Foot. The Thigh is called *Femur aferendo*, becauſe the creature is therewith ſuſtained or held vppe. The fleſhy parts are called by *Hippocrates* πλησίδες, the fore-partes παραμήρια. The Pulpie or fleſhy part about the ioynt belowe is (on the backeſide into which the Knee is bent) called *Poples* the Ham, becauſe it is folded *Post*, that is, backward: the fore-parte is called *Genu*, that is, the Knee. The ſecond part of the foote from the Knee to the Heele is called κνήμη or σκέλος, in Latine *Tibia*, we call it the Leg: the forepart whereof *Antetibiale* the Shinne, the hinder and fleſhy part *Sura* the Calfe: the two proceſſes without fleſh neere the bottome *Maleoli* or the Ancles. The laſt part of the foote is called *pes parnus* & properly the Foote, becauſe it is the baſis or pediſtall wherupon the whole body reſteth and it is the true organ or Inſtrument of progreſsion: & as the hand is diuided into three parts, the Wreſt, the After-wreſt and the Toes. The Wreſt is called *pedium*, and conſisteth of ſeuen bones, foure of which haue proper names, the other three none. The forepart of this *pedium* is called the inſtep. The backe part is round and is called *Calx* or the Heele, the lower part of it is called *Calcaneum*, becauſe with it wee do *calcare Terram* tread vpon the Earth, and we call it the pitch of the heele.

The partes of the foote in the large acceptation.

The ſecond part of the foote conſisteth of fiue bones and anſwereth to the After-wreſt of the hand, in Latine it is called *Tarſus*, the lower part of it is called the plant or the ſoale of the foote, the vpper part betwixt the Inſtep and the Toes is called *pectus* or *dorſum pedis* the breſt or backe of the foote. Finally, the Toes are fiue anſwering to the fingers of the Hand, and haue their owne orders, making three ranks called σκυλαλίδες, excepting the great toe. Theſe bones are ioyned by *Ginglymos*, and haue ſeede-bones for theyr firmer articulation: for theſe ſmall bones make the foote ſtronger when we ſtand ſtil or walk on; eſpecially if our way be through ſharpe places, where otherwiſe the toes might eaſilie be hurted if they could be turned backe with ſtones or any other higher or vnequall ſubſtance whereupon we ſhould tread.

The Vſe of the ſeed-bons in the foote.

And this is the true and ſuccinct deſcription of the Ioynts, wherewith wee deſire the Reader to reſt contented at this time, becauſe he ſhall finde a more accurate delineation of all the parts of them in their ſeuerall places in the Tractes following; beginning with the moſt compounded parts, and ſo proceeding till wee come vnto the moſt Simple and Similar.

The End of the Ninth Booke of the Ioynts.

THE TENTH BOOKE,

Of Flesh, that is, of the Muſcles, the Bovvels *and the Glandules.*

The Præface.

AS our ability, time & auocatiõs haue giuen vs leaue, we haue gone through our firſt diuiſion of the body of Man into the three Regions, Naturall, Vitall and Animall and the Ioynts. It remayneth now that we diſſolue euery one of theſe into thoſe parts whereof they are compounded, laying each apart by themſelues that their Natures and differences may better appeare. In this *Analyſis* or Reſolution wee will firſt begin with the *Fleſh*, which beſide that it maketh the greateſt part of the bulk of the Body, is alſo ſomewhat more compounded then the reſt of the Similar parts. Next wee will entreat of the Veſſels, that is to ſay, of the Veines, Arteries and Sinewes; for theſe are the Riuers or Brookes which conuay the Bloud, the Spirits, the Heate, the Life, the Motion and the Senſe, into all the parts and corners of this Little world. Afterward we will deſcend vnto the Griſtles, Ligaments, Membranes and Fibres: Parts, not onely Spermaticall and Similar, but alſo Simple, that is not Organicall. Laſt of all wee will come vnto the Bones, that is, to the foundation of this goodly Structure; the Pedeſtall or Columns vpon which the frame of the body of Man is reared and whereby it is ſtrengthened and ſupported. I know well that ſome Anatomiſtes of the beſt note, haue in their deliuery of this Art quite inuerted this order which we haue propoſed vnto our ſelues, beginning firſt with the Bones, and ſo aſcending by the Griſtles, Ligaments, Membranes, Veſſels and Fleſh, vnto the three Regions and the Ioynts: which Methode being *Geneticall*, we conceiue to be rather the way of Nature then of Art; for Nature firſt lineth out of the maſſe of Seede, the warp of the body, and after with the wooſe filleth vp the empty diſtances: firſt ſhe layeth the foundation, rayſeth the ſtories, bindeth the ioyntes and plaſtereth the walles, till it come vnto a perfect building. Art on the contrary takes it aſunder peece and peece, proceeding from that which is more to that which is leſſe compounded, till at length it come vnto the very ground-worke or foundation. This Method we haue followed till we are come vnto the Fleſh: Of which there are three kindes; one of the Muſcles, another of the Bowels, and the third of the Glandules. To the declaration of theſe three we haue deſtined this Booke, but begin with the Muſcles, becauſe they are more compounded then the reſt.

CHAP.

CHAP. I.

What Fleſh is, and how manie ſorts of Fleſh there bee.

FLeſh in Latine *Caro*, in Greeke σὰρξ, hath diuers acceptions amongſt the Ancients. Sometime in a ſtrict and proper acceptation it is taken for the fleſh of a Muſcle, as if a Muſcle and Fleſh wer both one thing: ſo *Hippocrates* vnderſtandeth it in the 16 Aphoriſme of the fift Section where he ſaith, *That bathes of hot Water will looſen the Fleſh*, that is, diſſolue the ſtrength of a Muſcle: & in the ſecond Section of his Book *de Fracturis* he calleth the Muſcles abſolutely fleſh, becauſe their cheefe part is fleſh. But moſt plainly of all in his Booke *de Arte*, where he ſaith, *All thoſe members which are compaſſed about with fleſh, which fleſh they call a Muſcle, all thoſe parts I ſay haue bellies.*

The diuers acceptations of Fleſh.

Fleſh and a Muſcle al one.

Sometime by fleſh we vnderſtand that ſimple part which is peculiar and proper to ech part of a mans body, and compaſſeth, gathereth together, and couereth the *Stamina* or fibres defending them againſt the rage of the naturall heate which would conſume & depopulate their very ſubſtance, as alſo againſt the heate and colde, and other outward occurrents.

The particular Fleſh of euery part.

Concerning this fleſh *Hippocrates* in his Booke *de Oſsium Natura* hath this ſaying, *The Fleſh is that which tyeth together and buildeth or reareth vp all the parts of this frame*. VVee out of *Galen* and the late VVriters doe take knowledge of foure diſtinct differences of Fleſh; one is fleſh properly ſo called, another is the fleſh of the bowelles, the thirde is the peculiar fleſh of euery part, and the fourth the fleſh of the Glandules or Kernelles.

4. Kinds of Fleſh.

The fleſh properly ſo called is a ſoft and ruddy part made of blood moderately dried, & is therefore called a bloody part and a hot part: ſuch is the fleſh of the Muſcles which is truly and abſolutely called Fleſh, ſuch is alſo the fleſh of the Gums and that in the nut of the yard.

What is fleſh properly ſo called.

The fleſh of the bowels *Eraſiſtratus* calleth *parenchyma*, as it were an affuſion or gathering together of blood. For he thought that the ſubſtance of the bowels did accrue or gather of blood yſſuing out of the Veines. But wee thinke that the bowelles haue a proper ſubſtance of their owne which is the principall and chiefe part of the bowell to which his action doth properly belong. There is alſo another fleſh peculiar vnto euery ſolide part, which fleſh hath no proper name, but *Galen* calleth it *Carnoſam ſubſtantiam*, the Fleſhye ſubſtance: for in the tenth Booke of his Method he acknowledgeth a double ſubſtance in the ſolid parts, the one exquiſitely ſolide and fibrous altogether without blood, another which ſtuffeth the fibres and filleth vp their diſtances, and is called the proper fleſh of euery part; this he thinketh is neuer reſtored if it be loſt but only moiſtned and cheriſhed when it is preſent. Such is the fleſh which is to be ſeene in the ſtomacke, the Guttes, the Gullet, the Bladders and the wombe. And ſuch a kinde of fleſh *Theophraſtus* attributeth vnto plants growing about their woody, and as it were ſinnowy fibres.

The fleſh of the ſolid parts

A twofolde ſubſtance of the ſolid parts

The common vſes of this three-fold fleſh *Galen* hath deſcribed in his twelfth Booke *De vſu partium*, to wit, that it ſhould defend the partes from heate and colde and other outward occurrences. For all fleſh is a ſoft pillowe for the creature when it either lyeth or falleth downe; when it is wounded it yeeldeth to the hardneſſe of the weapon; when it is bruiſed or beaten it filleth vp the breach as it were a boulſter of Lint: in the ſweltering heate of the Sunne it ſerueth for a ſhadow, and in the violence of cold it keepeth warme. And theſe vſes I haue called *Common*, becauſe there are other peculiar to each kinde of fleſh: for the fleſh of the Muſcles both mooueth voluntarily and alſo by his ſtuffing it hindreth the Chord or Tendon of the Muſcle, leaſt when it is contracted or drawne together it ſhould depart from the bodye, as alſo it eaſeth and moiſteneth the drowth of the Nerues and Ligaments, which they continuallie acquire by theyr perpetuall motion.

The common vſes of Fleſh.

The particular vſes of the fleſh.

The fleſh of the bowelles as it were a certaine ſtuffing or concretion, firſt confirmeth the veſſels of the bowels, next it filleth vp the empty places betwixt the veſſels; and laſtly it performeth a ſimiler and officiall action as we ſhall ſay anon. Finally there is a glandulus fleſh ſuch is the Pancreas a kernally body placed in the belly neere to the gate of the liuer: for ſome haue defined a Glandule to be a maſſe of fleſh rowled vp in it ſelfe. And theſe in my iudgement are all the differences and diſtinctions of fleſh. The particular hi-

The Fleſh of the Glandules

The order of this booke.

ſtory whereof, we wil as accurately and briefly as we may deſcribe vnto you in this following diſcourſe, beginning with the fleſh of the muſcles, as being a more compound and organicall part, and ſo proceeding to that of the bowells and glandules, which are more ſimple and ſimilar, originally detiued from the firſt conformation of the body.

CHAP. II. *Of the fleſh of the Muſcles, and what a Muſcle is.*

THe firſt and chiefe kind of fleſh, is that of the Muſcle, in the deſcription whereof becauſe of the variety and difficulty of the ſubiect, we muſt craue a little leaue ſomewhat to inlarge our ſelues. For it is far and wide ſpred ouer the whole body, and maketh indeed the greater part thereof. This is that which giueth ſtrength, proportion, and beauty to all the other parts, whereof if the body be diſpoiled, as it happeneth in the melting and diſſoluing heate of a hecticke ague, there remaineth nothing elſe but the image of a dead creature, nay of a dried and parched carkaſſe: which may ſeeme to be the reaſon that moued *Hipocrates* to call his booke wherein he treateth of the principles of the body and the nature of the particular parts (a worke which he compoſed in his olde age, as appeareth by the experienced certainty, maieſty and weight of the ſentences therein contained) *de carnibus* a booke of fleſh. The fleſh therefore when it is gathered together on a heape *Hipocrates* calleth a Muſcle in his booke *de arte* as we haue ſaide before, and againe the muſcles he calleth abſolutely Fleſh, becauſe the principall part of them is the fleſh. And in his prognoſtickes from the laudable and commendable habit or proportion of this muſculous fleſh he gathereth the perfect health of the whole body. And in the fourth Section of his Aphoriſmes and the ſixteenth, when he would deſcribe a haile bodie, he maketh mention onely of this fleſh, where hee ſayeth, *Elleborus dangerous to ſuch as haue ſound fleſh*, that is, ſuch as are in perfect health. For the muſcles are a kinde of of part both gouerning and being gouerned: they gouerne thoſe members for whoſe motion they were ordayned, and are gouerned by the Brain through the Nerues, by the Heart through the Arteries, and by the Liuer through the Veines: wherefore if theſe be in good plight (which is eaſie to bee knowne by the naturall figure, freſh and flowry colour, and their iuſt and due extent) they ſhow that the principall parts are in a good and commendable conſtitution. The Nature therefore, differences and actions of theſe Muſcles we haue taken for our preſent taske; wherein how fairely ſoeuer we ſhal acquite our ſelues, yet wee make account as in all other parts of this labour, ſo eſpecially herein, by reaſon of the difficulty to finde the trueth and diuerſity of mens opinions; we ſhall expoſe our ſelues to manifould cenſure and exception, vnleſſe wee light vppon the more equall Auditors. But to the matter.

Hippocrates conuerteth the names of fleſh & muſcles.

Wherein the laudable habit of a muſcle conſiſteth

The names of a muſcle.

A Muſcle is called in Greeke μῦς, that is, a *Mouſe*, either becauſe it is like vnto a fleyne Mouſe, or vnto the Fiſh which they call *Muſculus*. It hath alſo diuers Latine names, one from the Greeke, which is, *Muſculus*, and that we will incorporate or infranchiſe into our Engliſh, although the next Latine name, which is, *Lacertus*, in Engliſh a Brawne, might reaſonably wel be retained, had not vſe made this other more common. For we call an Arme full of ſound fleſh, a *brawny Arme*: but to hold the name of Muſcle.

A double conſideration of a muſcle.

There is a double conſideration to be had of a Muſcle; the firſt is, of the ſtructure or compoſition of it, the other of the office and vſe: and therefore there may be a double definition giuen of it.

If you regard the ſtructure, it is defined by *Galen* in *arte parua*. *A fleſh wouen of ſimple fleſh and ſimilar fibres*. And in the Booke of Phiſicall definitions it is called *A ſinowey body mingled with fleſh*. It may more fully be defined thus: *It is an organicall and diſſimilar part wrought together of Nerues, Fleſh, Fibres, Veines and Arteries, all couered or inueſted with a proper coate of his own.*

That a muſcle is an organ.

That it is Organicall, *Galen* teacheth in his Booke *de differentijs morborum*, in which place he reckoneth it amongſt thoſe Organs which are moſt ſimple and of the *firſt kinde*, becauſe it is not made of diſſimilar particles but of ſimple.

That it is Diſſimilar, the ſtructure of the parts being of diuers kindes doe euidently proue. The Nerues are the conuayers of the ſpirites and the faculties; the fleſh ſtuffeth the diſtances betweene the fibres that they ſhould not be mingled, tempereth the drynes of the Nerues and Tendons, preſerueth the threds or fibres that they bee not bruiſed or broken, and maketh the Animall ſpirites more apt to moue by his heate. The Fibres which are wouen of ſmall particles of the ligaments diuerſly diſheueled doe ſtrengthen

The partes of a muſcle and their vſe.

the

the flesh, establish and preserue it that it bee not dissolued: the veines like small riuerets are prouided onely for nutrition; the Arteries doe conserue the heate; the Coate inuesteth the Muscle, contayneth his substance, separateth and distinguisheth it from the adioyning parts and giueth it the sence of feeling. This is the structure of a muscle *according to them all*, to *them alone* and *at all times*.

There is another definition of a Muscle taken from his office which *Galen* deliuereth in his first Booke *de motu musculorum*. *A muscle*, sayeth hee, *is the instrument of that motion which is performed with violence*, or a *Muscle is the immediate organ of voluntary motion*. By violence *Galen* vnderstandeth that which *Aristotle* calleth *Spontaneum*, or voluntary which proceedeth from an inward principle, to wit, from a desiring or moving faculty. *Galen* calleth that which is Voluntary often times Animall to distinguish it from that which is Naturall: and in his Booke *de tremor: palp.* he calleth Muscles Organs which are moued at our discretion. The explication of the definition.

Now that motion is Voluntary which at pleasure we can appease, and againe excite or stirre vp when it is appeased, and make it swifter or slower, rarer or quicker as wee list.

This will or pleasure of man is double; one from Election, another from Instinct: the first we exercise when we are awake, the latter when we are asleepe or minde some other matter more. The first is a streatching or Tention not without strife or contention: the second is in remission or rather the remission it selfe of that contention or strife; & therfore they that are a sleepe do neyther moue their bodies into extreame & violent figures or postures, neither doe they accomplish the perfect *Tonica'l* motion, that is, the stedfast holding of the member, as those that are awake. What is voluntary motion. A double will from election and from instinct.

Of this Voluntary motion there are diuers instruments, the Braine, a Sinew and a Muscle, but one is immediate. The Brayne commandeth, the Sinew or Nerue carrieth the commaundement, and the Muscle obeyeth. The Brayne determineth of the obiect which is to be desired, whether it be profitable or noctious and hurtfull, to be followed or auoided: from hence therefore is the beginning and originall of the motion. When the action is agreed vpon by the Brayne, the Nerue which is the spirits vehicle carrieth down the faculty of mouing: the Muscle being illustrated or enlightned with the beames of the spirit is presently contracted and immediately moueth the part according to the diuersity of the commandement which it receiueth from the will. And as a horseman hauing the reynes in his hand dryueth forward or reyneth in the horse; so the fantasticke power of the Soule sitting in the Braine, by the Nerues as by a reyne or brydle moueth the muscles. Three organs of motion. How these 3. doe worke. An apt comparison from a man on horsebacke.

These things therefore are necessarily required to locall and voluntary motion, which in order doe follow one another. *An obiect appetible* or to be desired, *The faculty desiring*, and *a power to moue locally* The Brayne, the Animall spirites, the Nerues and the Muscles.

Wee conclude therefore that a muscle is the immediate instrument of voluntary or willing motion, whatsoeuer can be obiected against the trueth of this definition shall be heard, and receiue satisfaction in our discourse of the Controuersies annexed to this Booke.

CHAP. III. *How many and what are the parts of a Muscle.*

THe parts of a Muscle we will distinguish into similar of which the whole body of the Muscle is composed; and dissimilar into which the same body according to his length is deuided. The parts of a muscle.

The similar parts are Nerues, Fibres, Tendons or Chords, Flesh, Veines and Arteries. The dissimilar are three, the beginning, the middle, and the end; or the *Head*, the *Belly*, and the *Taile*. Out of these similar partes ioyned together and diuersly intangled with an admirable arte, resulteth an organ ordained for voluntary motion. But in this composition there is not the like worth or vse of all the particles, neither doe they meete together in the same degree or efficacy of operation.

Wherefore as before in euery perfect organ we obserued foure kindes of partes; the first of those by which the action is made originally and essentially; and to these *Galen* attributeth the preheminence or superiority: the second of those without which the action goeth not forward; the third by which it is better performed; the last of those which doe conserue the action or keepe it as wee say in tune: so all these foure differences of partes In all organs 4. kinds of parts are to be obserued.

a diligent Anatomiſt may obſerue in a muſcle. The fibrous fleſh is the prime and principall part of a muſcle, and as *Hippocrates* and *Galen* doe beleeue the proper ſubſtance of the ſame: for if you reuiew the whole body you ſhall finde none like it; when that is wanting or decayed the motion alſo is weake or none at all, and where it is there alſo is alwayes voluntary motion: this onely is prepared and fitted by Nature to receiue the influence of the *mouing quality*: this alone doth eaſily collect, contract and gather vp it ſelfe together, and looſneth and remitteth the part which it hath drawne: ſo alſo the chiefe part of all the bowels is ſayd to be their fleſh or *parenchyma*.

The fleſh is the principall part of the muſcle.

The Nerues which are diuerſly diſperſed into the Muſcles, are thoſe without which the motion cannot be: for they are the conuayers of the Animall ſpirits, and bring down from the throne or tribunall of the Soule, which is the Braine, the warrant and commandement to mooue: which if they bee cut, obſtructed, refrigerated, inflamed, or any other way affected, the motion periſheth inſtantly. The Ligaments and Tendons doe make the action more perfect; for the Tendon is not as we ſay in Schooles *ſimpliciter*, that is, originally and by it ſelfe ordayned for motion, but *ſecundum quid*, that is, for the performance only of vehement, ſtrong and continuall motions, and therefore there be very many Muſcles without Tendons.

The tendons make the action more perfect.

The Veines, the Arteries, and the Membranes, are they which conſerue the action; for the Veines and Arteries doe reſtore the waſting and decaying ſubſtaunce of the Muſcles, which by reaſon of continuall expence are waſhey and fleeting: and therefore they are in great aboudance diſperſed through the fleſh, becauſe as *Hippocrates* ſayth *Fleſh is a drawer*, and the bloud ought to be in greater quantity then the reſt of the humors becauſe the mountenance of the Muſcle ariſeth thereby. The Membrane as it were a garment or couering inueſteth and cloſeth the Muſcle and giueth it the ſence of feeling. And thus much concerning the Nature of the ſimilar parts of which the Muſcle is formed.

Hippocrates.

Now the whole body of the Muſcle is deuided into three diſsimular parts, the *Head*, the *Belly* and the *Taile*.

3 diſſimilar parts of a muſcle.

The Head is moſt commonly neruous, ſometimes but rarely flecty: for it is made of Ligaments ariſing from the bone, yet is it not altogether inſenſible becauſe of the inſertion and interpoſition of the ſinewes; for it is couered with a peculiar membrane.

The Head,

The Belly is the middle part of the Muſcle almoſt all fleſhy, and maketh the bulke of the ſame: and for that reaſon in the Legge they call the pulpe, that is, the brawne of the Calfe wherein the middeſt of all the Muſcles of that part doe ſo meete that they ſeeme to make but one Muſcle, they call it I ſay γαστροκνημίαν as it were *the belly of the Legge*, wee call it the Calfe.

The Belly.

The laſt part of the Muſcle is the End, the Taile or the Tendon, it is called ἀπονεύρωσις, becauſe it is almoſt altogether neruous. *Galen* thinketh that the Tendon is framed of the fibres of the nerues and Ligaments confounded and mingled together, yet ſo that there are more fibres or ſtrings of the Ligaments then of the Nerues, whence it is that the tendon is ſixe yea ten fould thicker then a nerue.

The Taile, whereof the tendon is made.

And the reaſon of this mixture is becauſe the ligament of it ſelfe and by his own Nature immoouable and inſenſible, could not alone performe a voluntary motion: and againe the nerue becauſe of his ſoftneſſe and ſlight or thinne texture was not able to draw the vaſt bulke or magnitude of the members: and therefore it behoued to make of them both a mixt organ which ſhould be harder and ſtiffer then the nerue for ſtrength, and ſofter and more pliable then the Ligament for motion: and ſuch is a Tendon partaking of the Nature of them both, ſo becomming of a middle diſpoſition betweene them; more ſenſible and weaker then a ligament, ſtronger and leſſe ſenſible then a nerue.

The reaſon of the compoſition.

Furthermore, we muſt remember that all muſcles haue not Tendons or Chords, as the Muſcles of the Tongue, the Teſticles, the Lippes, the Fore-head, the Yarde and the 2. Sphincters: but onely thoſe which are mooued either ſtrongly, or vehemently, or continually. Thoſe that are ordayned for the motion of bodies doe alwayes end and determine into Tendons either greater or leſſe, and are inſerted not into the iuncture or very ioynt of the bones, nor into the ends of that bone from which they ariſe, but for the moſt part into the head of the bone which is to be mooued wrapping it about. The Muſcles alſo which moue continually though their motion bee neither ſtrong nor vehement, yet they ſtand in neede of a Tendon: and therefore the muſcles of the eyes are not without them.

Why the ſmal muſcles of the eies haue tendons.

CHAP.

CHAP. IIII. *What is the action of a Muſcle, and the differences of the motions thereof.*

A Muſcle as it is an Animall Organ hath one and but one action to wit, Motion: the Nature of which Motion is not obuious or eaſily knowne of all. *Galen* in the eight Chapter of his firſt Booke *de motu muſculorum* acknowledgeth foure differences of motions in theſe wordes: *The Muſcles are eyther contracted or extended, or ſinke of themſelues, or elſe remaine ſtreatched or diſtended.* There are 4. motions of the muſcles.

Contraction is the proper and ingenit action of the Muſcle; for whileſt it moueth any part whether it houldeth it ſtedfaſt when it is bent, or bendeth it being before ſtretched or diſtended, it is alwaies contracted or drawne vnto his owne originall, that is, towards his head. Now that contraction is the proper action of euery muſcle, hence it appeareth that if the muſcle bee cut a two in the middeſt ouerthwart his body, you ſhall ſee the one part contracted vpward and the other part contracted downwards.

The ſecond motion of the Muſcle is Extention, which is not proper but aduentitious or accidentall: for when the contracted Muſcle is extended it is looſened by another and not by it ſelfe: and therefore almoſt euery muſcle hath ioyned vnto him a companion, nay rather an *Emulus Concurrent* or aduerſary, becauſe it is the author of a motion contrary to his: As for example, euery *flexor* or bending muſcle hath a *tenſor* or extending muſcle; euery *adductor*, that is, which moueth *toward* hath an *abductor* which moueth *froward*; euery *leuator* or lifting muſcle hath a *depreſſor* or ſinking muſcle. VVhen as therfore a muſcle which is contracted is alſo extended, in this extention it followeth the motion of his *Antagoniſt* or Aduerſary, ſo that the extẽtion is not the proper motion of the muſcle that was contracted, but rather his paſſion then his action. Extention the 2. motion of the Muſcle. Note this.

There is a third motion of a Muſcle which is yet more improper, in which it is neither contracted nor relaxed but falleth with his own weight, and this is called *tranſlation* or *decidence* and ſinking: this motion is not from the Soule but from the Elementary fourme, for the part not illuſtrated with the beames of the Animall ſpirite falleth with his owne weight, and ſo the part is moued the mouing faculty being at reſt. So *Galen* ſayth that the *tremor* or trembling, which the common people eal the ſhaking Palſey, commeth to paſſe by an equal contention or ſtrife betweene the mooning faculty and the moued member; for the faculty lifteth the member vp, and the waight of the member ſinketh it ſelfe again, and ſo from that viciſſitude or enterchange of lifting vp and falling down commeth the trembling. How trembling commeth,

The laſt motion of the Muſcle we call *Tonicall*, wherein the fibres of the Muſcles are ſtreatched and ſo remaine; ſo that the part ſeemeth indeed to bee immouable but yet in trueth is really moued. This motion is moſt euident in Birds when they flye or glide in the ayre with their wings ſtiffe ſtreatched and ſeeming immouable; a man alſo ſtandeth by this motion, and ſo a Piſmire moueth vpward vpon a ſtaffe as faſt as the ſtaffe deſcendeth downward. The laſt motion which is Tonicall. Examples of Tonicall motion.

Of this motion *Galen* ſpeaketh when hee ſayeth, that euen in ſleepe the Muſcles doe moue. There are therefore in all foure motions of the Muſcles, two performed by themſelues, and thoſe are contraction and the conſeruation of that which is contracted which ſecond motion is that we cal *Tonicall*: for ſuch is the Nature of ſucceſſiues or ſucceeding motions, that they are no leſſe accompliſhed when they are conſerued then when they are firſt made. 2. motions *per ſe*.

The two other contrary to the former are by accident, to wit, Extention and Deciſenſe; Contraction, Extention and the Tonical motion haue ſometimes extream ſometimes middle figures or poſtures. All extreame poſitions are painefull, thoſe that are meane are eaſie or pleaſant: the extreame wee cannot long endure vnleſſe wee bend our minde and power vnto it: the meane we eaſily endure when wee thinke not of it. And therefore whileſt we ſleepe we very rarely ſuffer any extreame flections or extentions of the Muſcles, and then onely when the fancy worketh exceeding ſtrongly: otherwiſe the Muſcles are inclined rather then bent to either ſide, as *Hippocrates* obſerueth in *Prognoſtico*: *They lye* (ſayth hee) *when they ſleepe with their Thighes, Handes and Feete moderately reflected or inclined, becauſe at that time the ſtrength of the Animall actions is not ceaſed but onely abated.* 2. other *per accidens*.

Men

Men alſo in their ſleepe haue not ſo ſtrong Tonnical motions as when they are awake, as we may perceiue in the ſphincter muſcles which ſhut vp the waies of the excrements, which perfourme indeede their Tonnicall motion in a good ſound ſleepe, but if the violence of the excrement be great they either ceaſe their motion and ſo the excrement auoydeth, or elſe the faculty being diſtreſſed calleth for more helpe, and ſo the party awaketh and becommeth more able to hould his owne. But it is worthy obſeruation that all muſcles when they moue are crooked, and when they reſt are ſtretcht: and the reaſon is, becauſe being contracted they become broader and ſhorter, and longer when they are relaxed: but from this generall rule, the muſcles of the Abdomen & the *Interceſtall* muſcles or thoſe betweene the ribbes are to be exempted, for when they are relaxed and the contention remitted they grow crooked, which I thinke happeneth by reaſon of the laxe and yeilding emptineſſe of the cheſt and the lower belly.

What the figure of the muſcle is when it worketh & when it playeth.

CHAP. V. *Wherein all the differences of Muſcles are ſhowne.*

All the differences of muſcles. The firſt.

THE Muſcles doe differ among themſelues in their ſubſtance, quantity, figure, ſite, originall, inſertion, fibres, parts, vſe and action. If you conſider the ſubſtance, ſome are fleſhy all ouer as the ſphincters and muſcles of the tongue · others are almoſt all neruous or membranous, as that *abductor* or fro-ward muſcle of the Legge which is called *Membranoſus* or *faſcia lata*, the broad Rowler.

The ſecond, The quantity conſidereth the dimenſions; now dimenſion is threefould. Length, and hence ſome Muſcles are long, as the right muſcles of the *abdomen* and the *abductor* of the Legge, and ſome ſhort. Bredth and hence ſome are broad as the oblique and tranſuerſe muſcles of the *abdomen*, and the broade muſcle which beareth down the arme, and others narrow: the laſt dimenſion is altitude whence ſome are thicke, as the two large muſcles called *Vaſti*, and ſome are thinne or ſlender; ſo much for the quantity.

The third, The figures of the Muſcles are manifould, ſome like a Mouſe, ſome like a Snake, ſome like a Plaice. Againe, ſome are triangle, ſome quadrangle, ſome fiue cornerd, ſome pyramidall or ſpiry, and ſome orbicular or round. To this kinde we may referre the Muſcles called *Deltoides*, *Rhomboides*, *Scalenus*, *Trapezius* and ſuch like.

The fourth. From the ſituation, the diuiſion or difference of Muſcles is very elegant: this ſite wee conſider in the poſition of the fibres and in the differences of place: from the poſition or tract of the fibres ſome muſcles are right, ſome oblique and ſome tranſuerſe. The oblique are are moſt fitte for oblique or ſide motions, the right for more exact flexion or extention.

The differences of the place according to the length doe make the muſcles higher or lower: according to the breadth, right and left: according to the height, forward, backeward, internall and external. Thoſe occupy the inſide which bend the part and thoſe the out ſide which doe extend it: and ſo much for the ſite.

The firſt, not. In reſpect of the originall ſome ariſe from Bones, and theſe now from their heads or extuberations when they behoued to be greater; now a little lower or from the cauities; ſometimes from one bone ſometimes from more; others from Griſtles, as the proper muſcles of the *Larynx* or throttle; others from a membrane incompaſsing the Tendons or Chords, as thoſe which are called *Vermiculares* or the wormy muſcles; others from other parts, as the ſphincters.

The ſixt. The differeence from the inſertion is, that ſome are inſerted into a bone, ſome into a Griſtle, as thoſe of the throttle and the eye-lids; others into a membrane, as thoſe which moue the eye; others into the skinne, as thoſe of the lippes; others into other bodies: ſome alſo there are which hauing diſtinct originals doe yet end and determine into one part: and ſome againe hauing but one originall are inſerted into diuers parts. And ſo much of the inſertion.

The ſeuenth. Now if you marke the texture of the Fibres, they are of one kinde almoſt in all Muſcles: and yet there want not ſome which haue two or three kinde of fibres manifeſtly appearing in them, as that which is called *Pectoralis* and *Trapezius*, as alſo the Muſcles of the Lippes, from whence come their diuers and different motions.

The eight. The eight difference of Muſcles, is from the diuerſitie of three parts; now by parts in this place I meane both the eſpeciall parts of the Muſcle it ſelfe, and thoſe parts or places wherein ſuch Muſcles are ſeated. The parts of the Muſcles are three as we haue ſayd, the

Head

Head the Belly and the Tayle. Moſt Muſcles haue but one Head, ſome two, and ſome three, from whence they are called *Bicipites* and *Tricipites*. The Belly ſometimes is one and ſometimes two as in the Muſcle which ſhutteth the lower Iaw and that of the bone *Hyois* which is at the roote of the Tongue, which Muſcles from their double bellies are called *Digaſtrici*. The Tendon is in ſome broade and membranous, in others round, in ſome ſhort, in others long, in ſome perforated, in others there is none at all, in others but one, and in others many Tendons: ſometimes alſo you ſhall perceiue diuers Muſcles to determine into one Tendon, as in the leg of the *Twins* & the *Soale* is made one Chord or Tendon.

From the parts in which the Muſcles are ſeated they haue alſo names to diſtinguiſh them from others, as *Cratophitæ* or temporall Muſcles, *Rachitæ* or *Spinati*, that is, *Thorny* Muſcles, and *Iliaci*, that is, Muſcles of the *Ilia* or *Flankes*. Finally the moſt neceſſary difference of Muſcles, as I thinke, is taken from their vſe and action. The action of a Muſcle is voluntary motion: therefore according to the variety of their actions ſhall be the differences of the Muſcles; which I am wont to referre to three eſpeciall ones. The firſt ſhall be this. Muſcles are either of a kindered, or of an aduerſe faction. I call thoſe a kin which do conſpire and agree into one and the ſame worke, as the two *Flexors*, and the two *extenſors*, the one of which vſeth to occupie the right, the other the left ſide. Thoſe of the aduerſe faction are called *Antagoniſts* oppoſites or Concurrents, which performe actions contrary or ſucceeding one to another. For euery Muſcle almoſt hath ſet vnto him another, whoſe action is contrary to his, as to a *flexor* is ſet a *tenſor*, to a *leuator* is ſet a *depreſſor* to an *adductor* is ſet an *abductor* onely we muſt except the two *ſphincters*, and the *Cremaſters* or hanging Muſcles.

Of their place.

The 9. from their vſe and action.

From the variety of action three differences.

What muſcles are a kinne.

What are Antagoniſts.

Thoſe that are a kinne are almoſt alwayes alike in magnitude, number and ſtrength, but the oppoſites are not alwayes ſo equall, but vary much according to the weight of the part which is to be mooued, or the vehemency of the action. So they are but two which bow the head, but to ſtretch it out and lift it vp there are twelue. Againe, there are many which cloſe the neather Iaw, and but onely two that open it: for heauy things or parts do eaſily fall with their owne weight.

Of theſe Muſcles which are of a kinne *Galen* hath left this rule. *As often as thoſe muſcles which are of a kinne are in oppoſite parts equall in number, magnitude and ſtrength, the reſolution of one makes the conuulſion of the other.* And of the oppoſites or *Antagoniſts* he writeth thus in his firſt booke *de motu Muſculorum*. *Of thoſe motions that ſucceed one another if one periſh the other muſt needs be taken away. For if that which extendeth bee cut aſunder, the part indeed ſhall be contracted or bent, but it ſhall alwayes ſo remaine becauſe the muſcle that ſhould extend is cut aſunder.*

A rule concerning muſcles that are a kinne.

Another concerning oppoſites.

The ſecond difference of Muſcles taken from the variety of their motion or action ſhall be this. Some Muſcles moue themſelues, others other bodyes. They which mooue themſelues are the *ſphincters* of the fundament and the bladder: they which moue another body beſide their owne mooue a bone, or ſome other thing then a bone. Thoſe which moue a bone doe end in Tendons either greater or leſſe: they which moue another thing beſide a bone, ſome of them haue Tendons, and ſome haue none. They which moue ſuch parts as are eaſily moued haue none, becauſe their motion is not vehement as the Muſcles of the Tongue and of the Teſticles, but the Muſcles of the Eyes haue Tendons, becauſe being continently and perpetually mooued, though it bee but a ſmall part yet it needes a ſtrong mouer.

The 2. difference of the muſcles taken from the actions.

The third difference.

The third difference of the Muſcles taken from the varietie of their actions reſpecteth their peculiar motions which are diuers; from whence they are called *Flexores*, *Tenſores*, *Attollentes*, *Deprimentes*, *Adductores*, *Abductores*, *Rotatorii*, *Circumagentes*, *Maſſeteres*, *Cremaſteres*, *Sphincteres*. That is, *Benders*, *Stretchers*, *Heauers*, *Sinkers*, *Too-ward*, *Fro-ward*, *Rowlers*, *Compaſſers*, *Mangers*, *Hangers* and *Binders*.

CHAP. VI. *Of the number of Muſcles.*

THE Authours of Anatomie haue not agreed vpon their verdict concerning the number of the Muſcles, neither to ſay trueth is the euidence ſo pregnant as to ingage a mans faith; ſome doe acknowledge more, and ſome fewer, ſome there are which looking with ſpectacles make many of one, and theſe increaſe the number, happily beyond the ſtint of Nature; ſome againe are ſo thicke

thicke ſighted that of many they make one.

Wee in this one Chapter will compriſe the whole forreſt and confuſion of Muſcles into a briefe ſumme. *Siluius* hath giuen them almoſt all proper names, either from their action, vſe, figure, or the ſimilitude of ſome outward thing, which becauſe they ſeeme to repreſent the matter with more life, and are beſide a great helpe to memory, wee will retaine them in our Hiſtory.

The number of the muſcles is vncertaine. *Siluius* his names.

The muſcles are 405.

The Muſcles therefore in the whole ſumme are foure hundred and fiue. Firſt 2. of the forehead, 6. of the eye-lids, on each ſide 3; two doe open them, and foure ſhut them. The Eye is rowled after a ſtrange volubility by 12. Muſcles, 6. in each eye, the *heauer*, the *ſinker*, the *too-ward*, the *fro-ward*, and 2. *rowlers*.

The outward Eare is moued by ſixe, 3. the right and 3. the left: two dilate the Noſtrils and 2. contract them. The Lippes haue nine, 4. moue vpward and as many downward, and the ninth is called *Buccinator* or the *Puffer*, *Winder*, *Sounder* or *Trumpeter*. The lower Iaw hath tenne which moue it vpward, downward, forward, backeward and on both ſides. The bone of the Tongue called *Hyois* (if at leaſt it may bee called a bone) 8. muſcles doe ſuſpend and eſtabliſh. The Tongue is moued like an Eele, vpward downward, forward backward and to the ſides, by 10. muſcles. The Choppes haue eight, 4. on eyther ſide which helpe the ſwallowing. The *Larynx* or Throttle is dilated, conſtringed, opened and ſhut by 14: foure common and ten proper. The Head hath likewiſe 14: ſixe greater and 8. ſmall ones. The Necke hath eight, 4. to bend it and as many to extend it.

A briefe inumeration of all the particular muſcles.

The Shoulder-blade hath all his motions performed by 8. peculiar muſcles, foure in each ſhoulder-blade, *Trapezius*, *Leuator Proprius*, *Serratus minor & Rhomboides*, that is, the Table, the proper Heauer, the leſſer Saw and the Plaice. The Armes are each of them moued with 8. their names are *Deltoides*, *ſupra-ſpinatus*, *latiſſimus*, *rotundus maior*, *pectoralis*, *Infra-ſpinatus*, *rotundus minor & ſubſcapularis*, that is, the halfe Lozenge or triangle; the *Ridge-blade* or *blade-ridge* muſcle, the broad muſcle or Pruritane or claw-backe, the great Bowle, the Pectorall, the Snaile, the leſſer Bowle and the Lurker. The Cubit hath foure, in each 2. benders and 2. ſtretchers: the 2. benders are called *Biceps & Brachiaus*: the 2. ſtretchers are called the *Long* and the *Short*. The *Radij* haue each of them foure, two fore-bowers, the *round* and the *ſquare muſcles*, and as many backe-bowers. The VVreſt is bent by two, and extended by other two. The Fingers (excepting the thumbe) haue 3. bendors, *Palmaris*, *Sublimis* and *Profundus*, the Palme muſcle, the Floating muſcle and the Deep muſcle, and foure ſtretchers; 4. *too-ward* which are called *Vermiculares* or the wormes, and 6. *fro-ward* called alſo *Interoſſei*, becauſe they lye among the bones; in all 17. The thumbe hath nine, 1. bender, 2. ſtretchers, 3. too-wards, and as many fro-wards. There is alſo in the little finger a peculiar muſcle which moueth it froward the reſt, ſo that in each hand there are 27.

The Muſcles ſeruing for Reſpiration are in all 65. of which 32. doe diſtend or dilate the Cheſt, and as many contract it. Valuable to all which for both vſes is the odde Midriffe. As for thoſe 11. internall and externall, which are fancied to bee betweene the griſtles of the ribbes we doe not acknowledge them ſayeth *Laurentius*. The *Abdomen* hath 10. muſcles, 4. oblique, 2. right, 2. tranſuerſe and 2. ſmall or pyramidall muſcles. The back is moued by ten, 5. on each ſide. The Fundament hath foure, 2. *ſphincters* and 2. *heauers*. The Bladder hath 1. *ſphincter*. The Teſticles haue 2. muſcles called *Cremaſteres* or hangers and ſuſpendors. The Yarde hath 4. The Thighes are each of them bent by two called *Pſoas* and *Iliacus*, and three ſtretchers, which are they that make the ſubſtance of the Buttocks, there alſo are too-ward muſcles and 6. froward, 2. *obturatores*, and 4. twinnes called *quadrigemini*, wherefore the muſcles of the thigh are in all 28.

The Legge hath foure benders called *poſtici* or the poſterne muſcles, and ſo many ſtretchers, the right, the 2. Vaſt & the *Crureus*; two are too-ward, the Long and the Ham muſcles, and 1. is fro-ward called *membranoſus*, ſo that the muſcles of the Legges are two and twenty.

The Foote hath 2. that bend it, that is altogether in the in-ſtep called *Tibiaus anticus* & *Peroneus*, and 4. which ſtretch it, 2. twinnes *Soleus* and *Plantaris*.

The Toes haue 2. benders, *Sublimis & Profundus* and 2. ſtretchers, 4. too-wards called the VVormes, 8. frowards called *Interoſſei*. The great Toe hath 1. bender, 1. proper ſtretcher, 1 too-ward and another fro-ward. There is alſo one peculiar fro-ward muſcle of the little Toe, ſo that in each foote there be 21. muſcles for the mouing of the Toes. The total

tall ſumme of all theſe in the whole body is foure hundred and fiue: whether thou wilt add more or make theſe fewer, for my own part ſaith *Laurentius* I do not greatly care, no more doe wee but haſte on to our peculiar Hiſtorie of the Muſcles of each part, beginning with thoſe of the Head.

CHAP. VII. *Of the muſcles which moue the skinne of the Head.*

WE haue ſaide before that the skinne of the Head is moued according to our good pleaſures, in ſome men all of it round about, but in moſt onely the skin of the forehead and the face. The Antients, as *Galen* for example in his 11. Booke *de vſu partium* and the fifteenth chapter, thought that this motion came from a thinne and muſculous ſubſtance which is ſubiected or lyeth vnder the skinne of the forehead and is vnited thereto as the palmes of the hands and Soales of the foote are vnited with their Tendon. But the late writers with more euidence of truth by curious obſeruation haue found out and allotted to euery part of the face his peculiar muſcles, for we call all that the face that may be ſeene outwardly. Some of theſe are in the forepart of the face, as the forehead, the Eyelids, and the noſe: others in the backe part of the head called *occipitium*; ſome on both ſides, as in the eares the lippes and the cheekes. *Galen.*

What wee meane by the Face.

The skinne of the forehead (which by his tenſion and corrugation, that is, ſmoothneſſe or wrinkling demonſtrateth the manifold affections of the mind) is mooued not onely by the helpe of the fleſhy membrane growne more fleſhy as *Veſalius* thought, and ſo being vnited to the fleſh vnder it, paſſeth into a muſculous ſubſtance furniſhed with right fibres, but alſo by two muſcles, as appeareth both by the courſe of their fibres and by their motions; the fibres appeare in theſe after the maner of other muſcles, and their motions is not like the motion of the fleſhy membrane. The skin of the forehead ſheweth the affections of the mind.

Falopius alſo and *Platerus* haue giuen them names. *Fallopius* calleth them the firſt paire mouing the skinne of the head, and *Platerus*, the muſcles of the affections. Theſe are ſeated in the forehead, and doe ariſe aboue where the haire determines ſometime as high as the crowny ſeame neare the temporall muſcles, the right at the right and the left at the left temple (where the fleſhy membrane cleaueth ſo cloſe to the ſcull-skinne and the ſcull it ſelfe, that it is altogether immooueable, that the forehead and the eye browes might be mooued when their membrane is at reſt) and toward the common ſeame which diſtinguiſheth the bones of the head from thoſe of the vpper iaw are implanted with right fibres aboue the eyes and the noſe into the skinne at the browes, as at the parts which are to be mooued: for when the browes are mooued they draw in a ſtraight line together with them the skinne of the forehead. I ſaid right fibres and not oblique as ſome haue thought and therfore Chirurgions muſt obſerue that in opening apoſtemations in that place, they make not their inſitions ouerthwart as the wrinkles of the skin doe goe, but according to thoſe right fibres. A good note for Chirurgions in opening Apoſtumations in the forehead.

Wee muſt alſo obſerue that theſe two muſcles are a little diſioyned in the middeſt toward the top of the forehead, and that is the reaſon why the vpper part of the forehead is not mooued; but at the toppe of the noſe, where alſo they become more fleſhy they are ſo ioyned that they ſeeme to be but one muſcle. But that they are two, not onely Anatomie but alſo reaſon and experience do teach; reaſon, becauſe Nature hath made all members double that the body might be equally ballanced: Experience, becauſe we finde that if one of them be either taken with the palſey or wounded ouerthwart, the affected onely looſeth his motion and not the other, whereas if there were but one, there ſhould be no motion at all. And *Columbus* maketh mention of a Cardinall whoſe left muſcle ſuffering convultion by reaſon of a wound he receiued aboue his brow, did notwithſtanding moue the halfe of his forehead. Againe, when we are mooued to diſpleaſure, wee contract and wrinkle the skinne in the middle of the forehead, ſo that the browes doe almoſt touch one another: which contraction of the skinne could not bee made if there were but one muſcle. That there are two muſcles. A Cardinall.

The vſe of theſe muſcles is by the contraction of their fibres to liſt vp the browes together with the skinne of the forehead, and vpon their relaxation to ſettle them againe. For the forehead is mooued as *Galen* elegantly diſcourſeth in his 11. Booke *de vſu partium* and the fourteenth Chapter becauſe of the eyes: for when the forehead is lifted vppe the browes alſo flie vpward and the eyes are better opened to ſee more at once. And againe, The vſe of theſe muſcles.

The muſcles which draw the skin of the head backward.

when the eyes are ſhut for feare of any thing which ſhould ruſh vpon them, they are better and more ſtrongly cloſed by the falling of the browes and the forehead. The muſcles which draw the sinne of the head backeward are two, one either ſide one, ariſing verie ſlender from the tranſuerſe line of the *occiput* or nowle of the head, into which line the ſecond muſcle of the ſhoulder-blade called *cucul'aris* or the Cowle doth determine: from this line doe runne fibres directly vpward and make theſe muſcles, which are very ſhort & not aboue an inch, but yet ſo broade that either of them toucheth the eare of his owne ſide, and they end into a thinne and broad Tendon, which ſeemeth to be made of the fleſhy membrane, and occupyeth or compaſſeth the whole head and the fore-muſcles of the eare, and ioyneth alſo together the muſcles of the forehead. The vſe of theſe 2. muſcles is to draw the Skinne of the Head backeward; and therefore *Columbus* thought that they drewe alſo the eye-browes and inſtanceth in the example of one *Iohannes Antonius Plateus*, who could moue the whole skinne of his head very ſtrongly as alſo could *Columbus* himſelfe. But as the muſcles of the forehead are neuer wanting, ſo theſe of the nowle and the fore-muſcles of the eares (as *Falopius* and *Platerus* haue alſo obſerued) are but ſeldome found.

Why ſome men can moue the skin of their head.

Aquapendens his muſcle of the eie brows.

Beſide theſe *Aquapendens* aſcribeth to the eye-browes a round muſcle differing from the circular muſcle of the eye-lids, becauſe that of the browes hath thicker and more fleſhy fibres, and beſide is ſomewhat larger; drawing the brow eſpecially downeward to the eye, and being like vnto a Ring attracteth alſo the lower lid very ſtrongly.

CHAP. VIII. *Of the Muſcles of the Eye-lids.*

Great differences amõg Anatomiſts concerning theſe muſcles

WHat the Motions of the Eye-lids are and their neceſsities, as alſo of what kind Voluntary or Naturall with other circumſtãces thereto belonging, we haue declared before in their Hiſtory. Nowe concerning the number of theſe muſcles whereby theſe motions are effected, I finde great difference betweene *Galen* and the late Writers, and amongeſt the late writers themſelues.

Galen and the ancients with whome *Veſalius* and *Syluius* doe agree do make two, deuiding the orbicular muſcle of which we ſhall treate anon into two: one lifting vp the Lid, the other bearing it downe. *Laurentius* is of the ſame mind for the deuiſion of this muſcle but not for the Vſe, for he thinketh that they both ſerue to ſhut the vpper Lid: ſo that it ſhould ſeem that *Galen* and thoſe that ſide with him did not know of any muſcle which ſhould open the eie. *Falopius*, *Platerus*, *Bauhine*, *Laurentius* and *Aquapendes* affirme that for the opning of the eye there is but one muſcle. *Columbus* and *Archangelus* ſay there are two; the firſt wee admit, the ſecond wee ſay ſerueth to rowle the eye. But to paſſe by theſe contentions you ſhall giue me leaue to reſolue the matter thus.

The motions of the Eye-lids are performed by two muſcles, one right in the vpper Lid which lifteth it vp, and the other round. The right muſcle (which *Galen* knew not, neither *Veſalius* nor *Syluius*, but *Falopius* challẽgeth the inuention of) which lifteth vp the vpper Lid [ta. 1.*] is ſeated within the concauity of the bones in the vpper part of the orbe aboue and neare the muſcle which lifteth vp the eye to which in figure it is very like, and fleſhy but leſſe, and ariſeth backeward at the in-let of the opticke nerue from the ſame originall with the other muſcles which mooue the eye, and being directly ſtretched to the vpper Lid is inſerted with a broade tendon into his end or cartilage. His vſe is by contracting his fibres inward to draw the vpper Lidde vpward (for the lower ſetleth into his place of his owne accord) and ſo vncouering the eye it openeth it.

The place of the right muſcle.

The orbicular or round muſcle. His poſition.

The ſemicircular or round Muſcle [ta. 1.*] is ſeated betwixt the fleſhy membrane & that which is produced from the *Pericranium* or Scull-skinne, and is membranous and very thinne or ſlender, yet a little increaſed by certaine circular and fleſhy fibres which he borroweth from the fleſhy membrane, and ſo ſtandeth halfe round in either Lid.

His original.

It ariſeth with a ſharpe beginning at the roote of the noſe in the great and inward angle of the lower Lidde where the common ſuture is betweene the heade and the vpper iaw, from thence it proceedeth all along the latitude or breadth of the ſame Lid, and

Progreſſe.

is inſtantly inlarged and returned to the outward angle toward the vpper part of the orb

And inſertion

and paſsing on by the vpper Lid is inſerted with a ſharp end into the vpper ſide of the inner angle, and ſo maketh an exact circle, compaſsing the outward circumference of both the Lidds. Yet *Falopius* excepteth the inner part of the great angle, from which it is

proh-

prohibited that it might not be altogether circular.

His vſe is, that being drawne toward his originall, it might at one and the ſame time moue the vpward eyelid downeward and the lower vpward, thereby ioyning and binding them together. And that this is ſo, it appeareth as well by the continuitie of the fibres in the circumference and in the angle, as alſo by the motion in the ſame angle, eſpecially if it be a little more conſtrained ſo as wee muſt needs winke ſomething withall: and this may be manifeſtly perceiued both by the ſight and by the touch. For nothing ioyned can be ſtrictly drawne together ſo as they touch one another, vnleſſe ſome parts be drawn vpward and ſome downeward. This muſcle in reſpect of his fibres which are continuall is moſt truely ſaid to be one, but in reſpect of the two lids may bee called two ſemicirculas muſcles: for being ſeparated they make a halfe circle, but ioyned together, they make it perfect. This muſcle *Galen* knew, and in his tenth booke *de vſu partium* at the ninth chapter, he prooueth how all the motions of the eye lids are abſolued by it, hee deuideth it alſo and addeth, that one of them draweth too the great angle toward the Noſe, and the other vnto the leſſe toward the Eare; and that when the firſt draweth the lid is depreſſed, but lifted vppe with the latter. But becauſe the fibres of this muſcle are continuall through the whole lid, although it alſo bee mooued vpward and downeward, yet is there no muſcle which hath right motion but onely this forenamed circular muſcle which draweth it vpward, indeed but rather toward the inward angle or corner, as it were to his beginning, as euery man may perceiue by touching that part in himſelfe; and yet I know that ſome thinke this motion proceedeth from the motion of the cheekes.

The vſe of this circula muſcle.

How this muſcle may be ſaid to be two.

Why it can be but one.

Wee conclude therefore that the motion of the lids is accompliſhed by two muſcles, one right, which being in the vpper lid eleuateth it; the other orbicular or round and is in both the lids, which when it is ſtretched doth at the ſame time draw the lower lid vpwards and the vppet lid downewards; and when there is need of a ſtronger contraction or cloſer ſhutting together, then alſo the orbicular muſcle of the eye browes whereof we made mention before is drawne in to bee aſſiſtant, like as when wee would open the eye more ſtaringly, the muſcles of the forehead do much helpe vs.

Concluſion.

Hee that would demonſtrate theſe nice and curious muſcles, muſt haue a very ſmall knife and very keene, wherewith he muſt firſt ſeparate the skinne in the meane time taking care that he doe not cut the fibres of the muſcle, eſpecially in the angles: then ſhall he ſeparate the muſcle below at the *Tarſus* or edge of the lid, and aboue at the eye brow. *Fallopius* in his obſeruations confeſſeth that he was a long time of the ſame opinion with *Galen* and *Veſalius*, but in the yeare 1553. tooke knowledge of his error, being admoniſhed partly by *Oribaſius* in his booke *de diſſectione muſculorum*, and the 29. chapter, and partly by diſſecting the eye of a fiſh called *Phoca*, which is the Sea-calfe, which fiſh mooueth both his Eye lids. But we proceed vnto the muſcles of the Eyes.

How theſe muſcles may be diſſected.

How *Fallopius* came to learn the right muſcle.

CHAP. IX. *Of the muſcles of the Eyes.*

BEcauſe our Eyes were giuen vs as ſpies and ſcout-watches that wee might purſue profitable things and auoyde whatſoeuer is hurtfull, Nature made not them immoueable, for then they ſhould haue diſcerned only that which was oppoſite vnto them, for ſo ſaith *Ariſtotle* in his ſecond booke *de partibus Animal.* & in the tenth chapter. We ſee *per directum*, that is, by a ſtreight line not in euery poſition ſaith *Galen*, becauſe oblique, ſide, backward, higher and lower obiects do not fall in with the ball of the Eye: Wherefore it behooued they ſhould be ſo diſpoſed that they might moue and turne themſelues on euery ſide at their pleaſure. Theſe motions according to *Galen* in the third chapter of his firſt booke *de motu muſculorum* are ſixe in number, and therfore each eye muſt haue ſixe muſcles, in beaſts there are ſeauen, eſpecially ſuch as goe on all foure, which deceiued *Galen* and ſome late writers, who were accuſtomed onely to diſſect the Eyes of brute beaſts, yet hath the Ape but ſixe: The ſeuenth where it is, may be deuided into two, three or foure. In men, as I ſayd, they are ſixe according to the ſixe motions of a mans Eye, foure of which motions are right, vpward, downward to the right hand & to the left: two motions are oblique, to which belong 2. oblique muſcles, whoſe vſe is to rowle the Eye about: notwithſtanding one of theſe is exactly oblique, the other partly right and partly oblique.

How many motions in a mans eye.

All theſe muſcles are ſeated on the backeſide of the Eye within the cauitie of the Scull whither they accompany the Opticke nerue: and ſo remaining in their poſition the

The figure of the Eye.

eye, and they together do make a pyramidall figure. [Tab. 1. fig. 6 and 7] Among theſe the thicker and more corpulent are the right Muſcles, which haue all the ſame ſtructure, original and inſertion, and do paſſe ſtraight all along the length of the eye, the oblique are leſſe fleſhy. Theſe Muſcles are all ſmall, that they might bee ſooner mooued, but that which helpeth moſt the volubility of their motion is the round figure (which is the ſwifteſt of all other motions as we may perceyue by the roundneſſe of the heauens) for by it euen in a moment they are conueyed ouer the one halfe of the ſky.

The quantitie of the Muſcles.

The foure right Muſcles meeting towards the roote of the Nerue Opticke, doe ariſe with a ſharpe beginning from the lower part of the Orbe which is made by the Wedge-bone, hard by the paſſage through which the Nerue of *Sight* doth yſſue.

Diuers opinions.

I know there be ſome who imagine that they ariſe from a mixture of the *Dura Mater*, and a Nerue of the ſecond paire. Others, from the Membrane which compaſſeth the Orbe of the eye, and that other Membrane which inueſteth the Nerue Opticke: ſome from the *Pericranium* as *Aquapendens*, but we will reſt vpon *Bauhines* opinion for their originall. Their whole bodies are fleſhy, and they beare out their bellies rounde when they come forward, and a little aboue the middle of the eye they determine into a broad thin and Membranous Tendon, where-with they compaſſe the whole eye before, and grow very ſtrongly to the horny tunicle neere vnder the Rain-bow in the great Circle: and theſe tendons ioyned together do make that nameleſſe coate of *Columbus*, and the halfe-tranſparent white of the eye: for I thinke that this whiteneſſe is cauſed rather by the Tendons of theſe Muſcles then by the coate which they call *Adnata* or the cleauing coate.

Veſalius. Platerus Bauhine.

Whence proceedeth the white of the eye.

But we will giue you a more particular deſcription of them ſeuerally. The firſt [tab. 2. fig. 1. 3. 4. ᵇ fig. 5. ᵃ] which is the third (according to *Galen* and *Veſalius*) is placed aboue, fleſhy and round, thicker then the reſt, and greater and ſtronger it is then the ſecond, lifting vp the eye toward the browes: for there is more ſtrength required to lift any thing vp then to pull it downe; it is called the *proud Muſcle*, becauſe the motion thereof lifteth

Figur 3 & 4. ſheweth the Muſcles of the eie ſeparated before and behinde with their Nerues. Figu. 5. Is the eie of an Ox, with his Muſcles ſeuered as Veſalius doth ſhew it.

C, the Muſcle lifting vp the eyelid.

D. 1, 3, 4. The right vpper muſcle of the eie in 3 & 4 with the Nerue.

E, 2. 3, 4. the right lower Muſcle of the eie in 3 and 4 with the Nerue.

F, 1, 2, 3, 4. the right external Muſcle of the eye.

G 1, 2, 3, 4, the right internal Muſcle of the eye.

H, 1, 2. 3, 4. the oblique ſuperior muſcle or the pulley, whoſe tendon is marked with *a* and the pulley with *b*.

1, 2, 3, 4. the oblique inferiour muſcle of the eye.

a 1, 2, the tendon of the oblicke ſuperiour Muſcle.

α, β, the ſecond Muſcle of the eyelid lying in the caultie of the eye, whoſe broade Tendon *β* is inſerted into the eielid.

γ, 5, the haires of the eyebrowes.

δ *e*, two right Muſcles leading the eye vpward and downward.

ζ, *n*. 5. Two right Muſcles mouing vnto the right and left ſide.

B 1, 5. two oblique muſcles lightly turning the eye.

x, *x*. The ſeauenth Muſcle which may be diuided into more.

vp

vp the eye with a kinde of diſdaine.

The ſecond [tab.2.f.2,3,4.ª f.5.ª] is placed in the lower part oppoſite to the firſt, and according to *Galen* and *Veſalius* it is the fourth: it draweth the eye downeward towardes the Cheekes, and therefore needed not to be ſo great as the former; for the eye declineth with his owne weight: it is called the depreſſor and the *humble* Muſcle, becauſe in baſhfulneſſe we draw our eyes downward toward the lower lid. The ſecond.

The third [tab.2.f.1,2,3,4,ª f.5.ª] according to *Galen* and *Veſalius* the firſt, is ſeated in the greater angle, and leadeth the eye inward toward the noſe, and is called the *To-leader* and *Bibitorius*, we may call it the *ſquinting* Muſcle. The third.

The fourth [Tab.2.fig.1.2.3.4.F fig.5.ª] the ſecond according to *Galen* and *Veſalius*, is oppoſite to the third, ſeated on the outſide of the eye which it draweth outward to the leſſer angle or to the temples, & is called the Fro-leader or the muſcle of Indignation or the VVayward muſcle. The fourth.

By theſe foure if they moue together the eye is drawne inward, ſtabliſhed and conteyned, which kinde of looke we in our language call a *wiſte-looke*, the motion the Latins call *Tonicall*.

The fift [tab.2.fig.2.3.4.I fig.5.B] is the fift alſo according to *Galen* and *Veſalius*, but the ſixt according to *Fallopius*, *Platerus* and *Laurentius*. It is ſeated on the outſide in the lower cauity, and ariſeth betweene the eye and the tendons of the ſecond and fourth muſcles (which is the reaſon why ſome haue thought that it taketh his beginning from the eie and is againe inſerted into the ſame) from that cleft which appeareth like a ſuture of the bone of the lower orbe where the firſt bone of the lawe is ioyned with the fourth: ſometimes it ariſeth with a fleſhy beginning from a bony ſcale. The fift.

It is ſlender, round, ſhort and exactly oblique, and paſſeth obliquely toward the outward angle, as it were to embrace the eye with a ſhort and ſomewhat round tendon, and is implanted with a thin and ſinnowy end in an oblique line by the Rainbowes ſide nere the inſertion of the ſixt muſcle: ſo that ſometimes the tendons of them both ſeeme one and the ſame. His figure. His implantation.

To recite here the altercations of Anatomiſts about this muſcle would rather intangle our Readers then giue them any great ſatisfaction; eſpecially ſeeing ſuch learned men to whome ſo curious diſquiſitions will not ſeeme tedious, may repaire to thoſe fountains from whence we haue deriued theſe riuerets: we paſſe vnto the vſe, which is by the contraction of his fibres to rowle the eye obliquely downward toward the outward angle.

The ſixt [Tab.2.fig.1.2.3.4.H fig.5.ª] ſo alſo according to *Galen* and *Veſalius*, but the fift according to *Fallopius*, *Platerus* and *Laurentius* is ſeated on the inſide and the vpper part yet vnder the right muſcles, and is partly right and partly oblique. It ariſeth from the ſame place with that which draweth the eie directly to the inner angle at the ſide of the opticke nerues paſſage on the backe of the orbe. The ſixt. His originall.

It determineth as well in man as in beaſtes into a round ſmall and long [tab.2.fig.1. and 2.ª] tendon almoſt at the vtmoſt skirt or edge of the inward angle. His end

This Tendon is reflected through a ſmall griſtle hollowed like a cane or pipe, and placed in the greater angle which *Falopius* firſt of all found out, and called it *Trochlea* or the pulley, and thence proceeding obliquely to the right angle [tab.2.fig.1. and 2.B but in the 3. and 4. fig. it is ſliuen from the bone] toward the vpper part of the eye, it is inſerted betweene the firſt and the fift muſcles ſomewhat oblique; all which time the foreſayde Tendon is compaſſed about with a certaine Ligament as it were with a ſheath. This Muſcle being drawne inward to his originall with his tendon, he turneth the eye in a circular motion to the inward angle. Theſe two the one aboue the other below, are called the Rowlers or the Muſcles of Loue: the ſixt alſo ſome call *muſculum trochlea*, or the Muſcle *of the Pulley*. His progreſſe. His inſertion.

The ſeauenth Muſcle which is for the moſt part found in bruite beaſtes [tab.2.figu.5.ª] is ſet vnder the former ſixe, and hath of it ſelfe that figure which the former ſixe doe together make: it is ſhort and compaſſeth round the opticke nerue [table 2.fig.5.A] yet is there ſome ſtatte betweene them; proceeding forward it is dilated, imbracing the whole globe of the eye at the roote; it maketh alſo a circle euen as the foure firſt neare the Rainbow did make a cirele with their Chordes: at his inſertion which is into the hard tunicle of the eye, it becommeth fleſhy and may be deuided into 3. or 4. ſo as *Galen* doubteth whither it be one, or double, or treble. The 7. muſcle. His figure. His inſertion.

His vse.

The vse of this muscle is to tye vp and strengthen the eies of bruite beastes hanging alwaies downeward that they should not fall with their owne waight; it also encompasseth the nerue opticke making his passage more straight, so as in violent concussions or motions it may neither leane against the bone nor be indangered by distention.

Why a man hath not the 7. muscle.

This Muscle, Nature or the God of Nature rather did not see needfull for man; because he hath a countenance erected vp to heauen; and if at any time he be constrayned to looke downeward, hee hath all the right muscles with their ioynt strength to sustaine the Eye, because they growe with their fibres to the membrane which compasseth the orbe.

How to make dissection to shew the muscles best.

To finde out the Muscles of the eye, when the braine is taken away you must cut the orbe at each corner euen to the nerue opticke with a Saw, hauing a great care least the *Trochlea* or Pully which is in the inner angle bee offended. Then you must separate the *Pericranium* from the bone, and breake the vpper part of the orbe backeward, then take away the fat, and so shall you perceiue the muscles of the eye-liddes and of the eyes themselues together with their vessels: and if you would obserue the proper and peculiar motion of euery muscle; you must preserue them in their proper position, and tye to euery one of them a thred not far from their tendons and then draw the thred. You may also take the eye whole out of the orbe together with the *Trochlea* which is in the inner angle, and so demonstrate what you please. And thus much of the Muscles of the Eye.

CHAP. X. *Of the Muscles of the outward Eare.*

ALthough most commonly mens Eares are immouable, and few there bee who haue any sensible motion of them; yet that the moouing faculty may flow into them is manifest as well by their muscles whose action is motion, as also by the nerues which thereabouts are commonly seene. Now the reason why this motion is so rare and so hardly perceiued is three-fould.

A 1,2, The muscle of the forehead and the right fibres there of.
B 1,2. The temporall muscle.
αβγ 2, His semicircular originall,
CE 1, the first muscle of the eye-lidde compassing the whole lid.
FD 1, the third muscle of the wing of the nose which endeth into the vpper lip.
GH 1, the muscle of the vpper lip.
I 1, the broad Mouse-muscle stretched ouer the cheeks and all the lower parts.
ζεθ the circumscription or circumference of this muscle.
I 2. The grinding muscle or the second muscle of the Iaw.
M 2, a muscle forming the cheekes.
N 2, the muscle of the lower lip,
O 2, a part of the fift muscle of the lower iawe called *Digastricus*, that is, double bellied.
QR 2, The first muscle of the bone *hyois* growing to the Rough artery.
S 2, the second muscle of the bone *hyois* vnder the chin.
The lower T in the second figure, sheweth the third muscle of the bone *hyois* streatched to the iaw. The vpper T in the second figure sheweth the insertion of the seauenth muscle of the head.
V V 2, two venters of the fourth muscle of the bone *Hyois*.
The backeward K (put instead of χ) sheweth the seauenth muscle of the head and his insertion at the vpper T.
κλ 2, The originall of the grinding muscle from the yoke-bone.
μ 2, the insertion of this muscle into the lower iaw,
ρσ 2, two beginnings of the seauenth muscle of the head.
T 2, his insertion into the *Mammillary* processe.

Table 3. Fig. 1. Sheweth the muscles of the Fore-head, the Eye-lids and the Cheekes.
Figure 2. sheweth the Muscles of the Nose, Lips, the lower Iaw and of the bone Hyois.

TABVLA. III.

FIG. I.

FIG. II.

The

The first, becauſe the muſcles of the Eares are ſo ſmall (*Galen* in the 6. Chapter of his 16. Book *de vſu partium*, calleth them but delinations of muſcles) and the nerues ſo thredy that a ſufficient quantity of moouing ſpirits cannot be conuayed through them. The first reaſon.

The ſecond, becauſe if they ſhould be moued, the hearing would be depraued or viciated, eſpecially mens eares being ſmal, and therefore Nature hath made recompence by the eaſie and ſpeedy motions of the Head whereby we turne on euery ſide to receiue the ſoundes; whereas in foure-footed beaſtes their eares being greater and the motions of their heades not ſo nimble, they are alwaies moouable to receiue the ſounds from euery ſide; with them alſo they driue away Flies which men can doe with their hands. Secondr. aſon

The third reaſon is becauſe mens eares are ſhort and griſtly, ſo as the muſcles and branches of the ſinnewes cannot be dilated in them. But ſuch as they are we owe the honour of their inuention to *Fallopius*. They are of two ſortes, Common and proper, and conſpicuous enough in thoſe men whoſe eares we can perceiue to mooue. Third reaſon

The firſt is common to the eare and to both the lippes, and is a ſmall portion of that Muſcle which is accounted the firſt of them which mooue the Cheekes, and the skin of the face called *Quadratus*, [tab. 3. fig. 1, 1] or the ſquare Muſcle. This ſometimes becommeth fleſhy and aſcending with his Fibres to the roote of the eare [tab. 3. fig. 1 °] is inſerted vnder the lap, and draweth it downward to this or that ſide. This Muſcle is broade, thin and foure ſided.

The ſecond, which is a proper muſcle [tab. 3. fig. 1. neere to * Tab. 4. fig. 1. ** fig. 2. ‡] is ſeated in the fore-part, and lyeth vpon the temporall muſcle, ariſing from the vpper end and extremity of the muſcle of the forehead, where it toucheth with the temporall: this deſcending towarde the eare becommeth narrower, and at his inſertion into the vpper part of the eare very tendinous; it is thin being produced out of the fleſhy Membrane, which is but ſprinkled with fleſhy fibres, as alſo are the other Muſcles of the eares: it is much leſſe then the temporall, and from roundneſſe becommeth long. His vſe is to His originall. His inſertion.

Table 4. Fig. 1. ſheweth the skinne of the Head together with the Fat and the glandules vnder the eares, and the Muſcles of the hinder part of the head and the Eares.

Figure 2. ſheweth the Muſcles of the eares, of the Eyebrowes, and a few of the lawes.

FIG. I.

BB. The Muſcle of the eare ſpringing from the *pericranium* or Scul-skin.

C. The triangular muſcle mouing the skin of the nowl of the head.

The ſecond Figure.

A. The ſemicircular Muſcle of the eare, drawing the outward eare vpward, which is noted with B in the firſt figure.

B, C, D, E, F, G. the Muſcle as it were diuided into three parts, called *Tripartitus*.

H, the hinder part of the outward eare into which the foreſaid Muſcle is faſtned.

NNN, the circumference of the temporall Muſcle.

O, the Muſcle yet couered with the *pericranium*.

P, the Membran couering the ſaid muſcle drawn aſide

QQQ. The fleſhy part of the temporall Muſcle.

V. The Muſcle *maſſeter* or grinding Muſcle, remooued here from the yoake-bone, whence it hath his originall, that the implantation of the temporal muſcle into the proceſſe of the iaw might appeare.

X, the Muſcles making the cheekes.

Z, A Muſcle of the lower lip.

a a, the Muſcle of the eyebrow.

b b, the vpper eyelid hauing a Muſcle with tranſuerſe Fibres.

c, the eyebrow hauing a circular Muſcle, whereby the external parts of the eye are exceedinglie confirmed, as *Placentinus* ſaith.

draw

draw the eare vpward and foreward.

The third. The third [tab.3.fig.1 neere to O] ariſeth from the nowle or *Occipitium*, and from the couerings of his Muſcles aboue the Mammillary proceſſe or teat-like extuberation, wher the Muſcles that mooue the head and the ſhoulder-blade do end. In his beginning hee ariſeth narrow but paſsing downeward ouerthwart becomes ſome-what broader, as if it were diuided into two or three fingers, and is ſo implanted on the backe ſide of the eare to draw it backward and ſomething vpward.

The fourth. The fourth proceeding from the ſame Teate-like extuberation or Mamillary proceſſe, vnder the Ligament of the griſtle of the eare, is of a broad, fleſhy and fibrous ſubſtance, but in his progreſſe becommeth narrower till it end in a Tendon, which tendon is faſtned into the whole roote of the eares griſtle [Table 4.fig.2 H] one part of it aboue another part in the middeſt, and the third below. And hence it was that *Placentinus* a ſtudious and painfull Anatomiſt, out of this maſſe maketh three [Tab.4.fig.2 ACDIFO] muſcles led hereunto by his inſertion; all which notwithſtanding he ſaith do ariſe confuſedly out of one place.

Placentinus his conceite.

CHAP. XI. *Of the Muſcles within the Eares.*

The motion within the eare. BEcauſe theſe Muſcles are very ſmall, euen the ſmalleſt in the whole bodye, and beſide their poſition depending vpon the curious parts of the eare, we haue deſcribed them more at large before in the nineteenth chapter of the eight Booke, wherefore heere wee will onely make a little mention of them and trouble you no further in this place. The Hammer and the Anuile haue but a vorie obſcure motion, yet are they mooued, together with that Membrane whereto the Hammer is tied, vpward and downward by one Muſcle within the membran & another without it. The inner muſcle [tab.5.fig.2.] was firſt deſcribed by *Euſtachius*, & is ſeated in the Rock-bone. It is the leſt in the whole body, ſo alſo it is of the moſt elegant and dainty compoſition. It ariſeth in the baſis of the bone called *Sphenoides*, or the wedge bone in that place where with the roote of the proceſſe of the Rocke bone and an addiment of the Nowle-bone, it maketh a broken hole. His beginning is like a Ligament, afterwarde it becommeth fleſhy, and by degrees euen vnto the middeſt groweth a little broader, after becomming narrower againe, it endeth into two exceeding ſmal tendons, [tab.5.fig.5 belowe] whereof one is infixed in the higher proceſſe of the Hammer, and the other vpon his necke. This Muſcle draweth the head of the Hammer obliquely forward and inward, leadeth it from the Anuile, and driueth the Membrane outward from the crooked proceſſe of the Hammer.

The ſmalnes and elegancie of it.

This fift Table is all one with the eleuenth Table of the eight Booke.

The ſecond Muſcle. The other Muſcle, is ſeated about the middeſt in the vpper part of the Hole of Hearing, called *Mearus auditorius* without the Membran of the Tympane or Drumme. And about the inuention of this Muſcle, two of the beſt Anatomiſtes of *Padua* in *Italy* dooe contend.

The firſt inventers thereof. For *Hieronimus Fabricius ab Aquapendente* affirmeth, that he found it in the yeare, one thouſand fiue hundred ninety nine. Alſo *Iulius Caſerius Placentinus* ſaith, that hee obſerued it firſt the ſeauenth day of March, in the yeare one thouſand fiue hundred ninetie three. Which of them was the firſt inuenter I cannot ſay, but both their diligences deſerue great commendations.

The vſe both of the former internall, and alſo of this externall Muſcle *Aquapendens* expreſſeth on this manner.

The vſe. The vſe of theſe Muſcles is to preſerue the Membrane, which being in danger to bee broken or ſtretched in two places, both within and without; Nature hath prouided a defence on either ſide. For on the outſide the externall aire being violently mooued together with the ſound, might driue the Membrane inward: and within the Included ſpirit or the aire paſsing from the mouth into the paſſages of Hearing, might offer violence vnto the ſame membrane by driuing it outward, as in oſcitations or yawning gapings, in blowing of the Noſe, in retention of the breath, in ſtrayning of the Voyce, in emptying the belly, and ſuch like: and therefore the outwarde Muſcle beeing drawne

The prouidence of Nature.

inward

inward together with the membrane by the violence of the aire doth with his owne motion retract it outward againe, and contrarywiſe the inner muſcle when the membrane is thruſt outward retracteth it backe againe inward: and thus theſe two muſcles keepe the membrane from breaking. And truely it is very neceſſary that this office of the cuſtody of the membrane ſhould be committed to a muſcle and not vnto a ligament: that as the impulſions or motions of the aire againſt the membrane be diuers, ſo the cohibition or reſtraint and retraction of the membrane toward his owne ſeate ſhould alſo bee diuers. Now we know that a ligament worketh alwayes after the ſame tenour or manner, but the muſcles as being more voluntary doe worke with a kinde of proportion and meaſure contracting or relaxing more or leſſe as neede requires, and with a diuers motion reſiſting, yeelding to or amending the impulſions and agitations of the aire: thus farre *Aquapendens*. He that deſires further ſatisfaction about theſe muſcles let him looke backe to the 19 Chapter of the eight Booke.

Why theſe muſt needes be muſcles not ligaments

CHAP. XII. *Of the muſcles of the Noſe.*

BEcauſe the motion of the wings of the Noſe is very requiſite in ſodaine & large inſpirations and expirations, therefore Nature hath made them mooueable with voluntarie motion, for which cauſe there are certaine muſcles inſerted into them. For albeit the dilatation and conſtriction of thoſe wings might bee done by the muſcles of the lips which alſo touch them (as alſo the firſt muſcle of the cheeks which is made of the fleſhy membrane [tab. 5. fig. 1. 7] & inſerted into the root of the noſe) yet we haue obſerued in them that haue large noſes called *Naſuti*, ſome muſcles peculiar vnto the noſe it ſelfe, and theſe are of two ſorts: ſome ſeruing for dilatation, others for conſtriction. I am not ignorant what a medly of opinions there is amongſt Anatomiſt concerning the number vſe and ſcituation of theſe muſcles: but I will content my ſelfe in this place to follow *Bauhinus* onely.

Why the noſthrils haue motion.

They are of two ſorts.

The muſcles therefore which ſerue for dilatation of the wings of the noſe are foure, two very ſmall ones which ariſe one either ſide one from the cheeke bone (neare vnto the third muſcle of the lips) & the bony canale or pipe which is neare the noſthrils. Theſe are more fleſhy then ſinowy, and proceede ouer the ridge of the Noſe & are inſerted partly into the outward wing, partly into that part of the vpper lippe which they call *Filtrum*.

Muſcles of dilatation.

The vſe of it is to draw that part of the lip together with the wing of the noſe outward and vpward whereby it alſo openeth the noſthrils. (Tab. 5. fig. 1. F.) For as ſaith *Varolius* becauſe we ſmell by a kinde of Traction, together with the wings of the noſe the noſthrils alſo doe cloſe and are ſomewhat obſtructed; and therefore in ſmelling the holes of the noſe which wee properly call the noſtrils are by theſe dilating muſcles opened and ſo kept.

The vſe.

The two other muſcles doe ariſe with a ſharpe and fleſhy beginning from the ſuture or ſeame of the forehead where they are mingled with the ends of the forehead muſcles vnto the middle of the diſtance between the eys and the ſpine of the noſe: their form is almoſt Triangular, and they deſcend downeward obliquely aboue the bones of the Noſe, where becomming broader they are implanted into the wings, and with their right fibres do draw them vpward and dilate them.

The 2. other muſcles of dilation.

There are alſo foure muſcles which doe conſtring or contract the Noſe, two of which doe ariſe fleſhy about the rootes of the wings, but they are very ſmall: theſe paſſe ouerthwart aboue the wing and imbrace it, and are inſerted at the corner of the noſthrils. The vſe of theſe is that being contracted to their originall they preſſe downe the wing, & ſo ſhut the Noſe, [tab. 5. fig. 2. neere K.] The other two are hid within the cauity of the Noſe vnder the coare wherewith the hole is compaſſed: theſe are very thin and membranous, and doe ariſe from the extremity or end of the bone of the noſe, and are inſerted into the wings; which wings by drawing them inward they conſtringe or ſtreighten, and theſe muſcles as alſo all the reſt in this chapter deſcribed are not found in all, but in ſuch onely as haue large noſes, as we ſaid before. [Tab. 5. fig. 2. vnder K.]

The foure muſcles of contraction.

CHAP.

CHAP. XIII. *Of the common muſcles of the Cheekes and the Lips.*

Foure common muſcles. The ſquare muſcles.

THE muſcles which are common to the Cheekes and the Lippes are foure, two on either ſide called *Quadratus* and *Buccinator*, the ſquare muſcle and the Trumpeter. The ſquare muſcle [tab.6.fig.1.γ,δ,ε,ζ,η,θ. make the circumſcription,] or as *Galen* calleth it, the muſculous dilatation, or the broade or thin muſcle, becauſe it is large and membranous lyeth vnder the skinne of the necke, and alſo is ſpred ouer the lower part of the whole face from vnder the mouth. It is a membrane encreaſed with fleſhy fibres which yet doe not ariſe from any bone: theſe fibres do aſſend vpward to the middle of the face, creeping by degrees with a variable courſe from the regions of the racke-bone of the necke, on the outſide of the ſame where it ſwelleth moſt, of the ſhoulder blades, of the cannell bones and of the breſt bones, and ſo make a broade and thin muſcle.

Whereforeif any man ſhall deny it the name of a muſcle, and ſay it is but a membrane of muſculous Nature and ſubſtance, or whether he liſt to call it a muſcle, hee ſhall haue my good will, for it is ſo thin and ſo membranous that the ancients did not ſeparate it from the skin but fleyed it off therewith; not acccounting it in the number of the muſcles, as *Galen* ſaith who himſelfe was the firſt that deſcribed it, as appeareth in his fourth booke of Anatomical adminiſtrations, and in his firſt book of the diſſection of muſcles, although he knew it not when he wrote his books *de vſu partium*. To this membrane many ſmall branches of nerues are ſent from the ſinews of the neck & mingle themſelues with the fibres; & that is the reaſon why the membrane in this place is more ſtrongly vnited to the parts then in any place almoſt of the whole body, and the ſame diſſemination of the nerues cauſeth thoſe diuers fiberous paſſages which are ſeen in it. For from the breaſt bone and the middle of the clauicle his fibres run right in the length of the necke, [from δ to ζ] and thoſe which beginne from the other parts of the clauicle, from the toppe of the ſhoulder and from the reſt of the parts before named, doe trend obliquely vpward, [from θ to O and H.] and the neerer they are to the ſpines of the racke bones of the necke the more oblique do they appeare; ſo that when they come neare the *occipitium* or nowle of the head they are almoſt tranſuerſe: and yet for all that theſe fibres make no interſections in the neck at all, eſpecially that are viſible: but when they come vnto the Chin where the vpper lip is ioyned with the neather, [betweene H. and ζ.] eſpecially at the lower lip they are ſo confounded together that they can bee no more diſtinguiſhed. We call it the ſquare muſcle becauſe it paſſeth from the vpper part of the necke by the ſides of the nowle bone away, toward the eare, & is ſomtime implanted with fleſhy fibres into the root therof, by the help of which

[*Table 6. is the ſame with that in the Folio 750.*]

fibres in thoſe men who haue this poſition of this muſcle their eares, as we haue ſaid, are moued. Sometime vnder the roote of the eare [O] it paſſeth into the face, and couereth the *Maſſeter* muſcle of the Iaw, and withall groweth more ſtrongly to the Cheeke bone then other where, inſomuch as ſome haue taken this part of it to be the fifth muſcle of the Iaw: and from hence it is inſerted into the roots of the Noſe. The other ſide of it is ouerthwart the face, [from ° by " to ζ.] The third ſide from the top of the ſhoulder to the breſt bone, [from θ by ε to δ] and this side is very vnequall and as it were indented. The fourth ſide to make the quadrature, is from the top of the chinne to the breſt bone. [from ζ to .] Theſe muſcles doe moue the skinne of the face which is not moued by the muſculous ſubſtance of the forehead, the nowle, the eares and the noſe, or by any of their muſcles or by the muſcles of the eye lids: But rather as the right ſquare muſcle draweth and mooueth both the vpper and the lower lippe vnto the right ſide: ſo the left draweth both the lippes obliquely downeward to the left ſide: and becauſe they cleaue faſt vnto the chinne, therefore they helpe much the opening of the mouth. This is that muſcle ſaith *Galen* in his 1 book *de diſſect. muſculorum*, which firſt of al in thoſe that begin to be afflicted with conuulſions is intended or ſtretched, from whence come thoſe conuulſions which we call Cynicke or Dogge-ſpaſmes, becauſe by the contraction of theſe, men are conſtrained to writh and grinne like Dogges.

The fibres of this muſcle *Galen* in his firſt booke *de Anatom. Adminiſt.* counſelleth the Chirurgion to be well aduiſed of, becauſe of their inciſions which ſometimes are very neceſſary in this part. For ignorant Chyrurgions not knowing their courſe haue by large tranſuerſe ſections deuided them ſo farre that the cheekes haue flowne upward from the skin vnderneath them.

The antients before *Galen* knew it not.

Galen found it out.

The reaſon of the many & diuers fibres in in it.

Why it is called the ſquare muſcle.

The vſe.

The dogge-ſpaſme.

The

The Muſcle called *Buccinator* (either becauſe it maketh the Cheeke which is called *Bucca*, [ta. 6. fig. 2.ᴺ] or elſe becauſe it ſtrutteth in blowing or ſounding of the Trūpet which is called *Buccina*, & therfore we call it the Trumpeter) lyeth vnder the former and comprehendeth all that part which is blowne vp when we ſound a Trumpet. It is round and ariſeth almoſt from the whole length of the vpper Iaw and is inſerted into the length likewiſe of the lower Iaw at the rootes of the Gummes; or if you liſt to thinke with *Columbus* & *Laurentius* it ariſeth from the top of the Gummes, and like a circle doth againe determine into the top of the Gummes. For it being like a circle wherein the beginning, the middle and the end are all one, it skilles not much whether you ſay it proceedeth from below vpwards, or from aboue downewards. The Trumpeter. His ſcite. His originall. His inſertion.

Thinne it is and membranous wouen with many fibres, from whence come the variety of the motions which it performeth, within and without, aboue and below. To this Muſcle on the inſide, the coat which compaſſeth the mouth groweth ſo faſt that they cannot be diſſeuered but one of them muſt be broken. The ſubſtāce of it.

The vſe of this Muſcle is whileſt the Iaw reſteth to moue the Cheekes and the Lips, and yet euen in eating when the meate is fallen into the Cheekes, it ſerueth as a hand to reach it againe vnto the Teeth and to driue it hither and thither amongſt them, that the Aliment might be better broken and ſhred, and ſo prepared to bee boyled into Chylus in the Stomacke. The vſe.

Beſides theſe there is a double vſe of the Cheekes and of their cauities as *Archangelus* hath well obſerued. The firſt, that if any thing in eating doe fall from the Teeth outward it ſhould not be loſt but be kept within the Cheekes: the other vſe is that they might be places of receite to containe the meate while the teeth bee ready for it; as wee ſee in Apes which fill the puffes of their checks with meate which afterward they chew. Moreouer, in man they help much for pronounciation and in winding of a Horne or Corner and ſounding of a Trumpet; for if theſe cheekes be puft vp a man may obſerue the diuers motions of this Muſcle by rowling his mouth outward, vpward, downeward, forward and backward. A double vſe of the cheeks.

CHAP. XIIII. *Of the proper Muſcles of the Lippes.*

THE vſe of the Lippes in all creatures is for Eating and Drinking, and therfore Nature hath prouided their Lippes according to their Dyet. The Aſſe can mumble a Thiſtle as well as a Man can eate Lettice, whence the prouerbe is, *Similes habent Labra Lactucas*, Like Lettice like Lippes. But becauſe there is another vſe of the Lippes in men, for forming of wordes, for caſting forth of ſpittle and to preſerue the Teeth from the coldneſſe of the Ayre (that I ſpeak not of the ornament which they are to the mouth yea to the whole face) for theſe reaſons I ſay, it was neceſſary that the Lippes ſhould haue voluntary motion, and ſo the inſtruments of the ſame, that is, muſcles. The proper vſe of the lips in men.

Many of the Ancients and late writers alſo thought that both Lippes were mooued by the onely helpe of the broade Muſcle before ſpoken off, becauſe the great variety of his fibres they thought ſufficient for the accompliſhment of all neceſſary motions in that part. But the more diligent Anatomiſts, beſide thoſe aboue named common to the Lippes and the Cheekes haue found out other proper muſcles belonging to the Lippes alone, about the number whereof they doe not agree. Wee for this time will conclude that they are ſixe, on each ſide two belonging to the vpper Lip, and on each ſide one belonging to the neather. The opinion of the ancients. 6. proper muſcles of the Lippes.

The firſt paire of the vpper Lip [table 6, fig. 1, **] ariſeth from the vtter ſeame of the Iugall or yoke-bone, and that which ſeparateth the firſt bone of the vpper Iaw from the third and from the cheek-bone. In their beginning they are broad and fleſhy, and diſcend obliquely forward, inſerting themſelues into the ſides of the vpper Lippes, which they moue vpward and downward, inward and outward: and that by reaſon of their diuers fibres diuerſly commixed among themſelues and wouen with the skinne: from which notwithſtanding if the body be muſculous or fleſhy and not fat and the workeman diligent, it may be after a ſort ſeparated.

The ſecond paire [ta. 6, fig. 1, vnder H] ariſing fleſhy, round and couered with much fat, from the cauity vnder the checkes, is inſerted into the bridle where the Lips do meet, and they ſay it turneth the vpper Lip downward. The ſecond paire of muſcles.

The

Table 7. figure 3. ſheweth ſome muſcles of the iaw, the Larynx and the bone Hyois.
Figure 4. ſheweth ſome parts lying in the mouth.

TABVLA. VII.

FIG. III.

FIG. IIII.

A, A hole in the forehead bone, ſending a ſmall Nerue into the brim of the ſeate of the eye.
B. the tempotall Muſcle.
C, A fungous ſubſtance of the lip, together with the nerues ſtretched on both ſides vnto it.
E A hole in the cheeke bending a nerue vnto the face.
G, A part of the yokebone here taken away.
I, the *Maſſater* or grinding Muſcle.
K, A portion of the vii, muſcle of the head cut away.
L, the bone *Hyois* bared from a few muſcles.
M, the Buccinator or Trumpeter.
m, the vi. muſcle of the bone *hyois* according to *Falopius*
O P, the double bellied muſcle of the iaw.
Q, the 2 of the common muſcles of the Larynx.
R, the firſt of the common muſcles of the Larynx.
S, A portion of the ſecond muſcle of the head.
V, V, 2. Venters or bellies of the 4 muſcle of the *hyois*.
X, the fourth Leuator or heauer of the ſhoulder-blade.
Y, the firſt muſcle of the Cheſt vnder the Coller bone.

Fig. 4. A, A portion of the Temporall muſcle.
B, A ſharpe proceſſe of the lower Iawe into which the temporall muſcle is inſerted.
* The palate.
C, the left part of the lower iaw.
D, the 4 muſcle of the lower iaw lying in the mouth.
E, the *Gargareon* or *Vuula*.
F, the vpper Glandules at the *Vuula*.
G, the lower Glandules at the Larynx.
H, the muſcles of the head and the necke mingled.
I, the tongue with the *Epiglottis* or ouer-tongue.
K, the rough artery bared from the muſcles.
L, the bed of veſſelles neere the Larynx, and the firſt muſcle of the backe.
N, O. The fift muſcle of the lower iaw called *Digaſtricus* hanging from his originall.
X, the 4 muſcle of the ſhoulderblade ariſing from the necke.

The lower lip hath one paire [Tab. 4. fig. 2. Z. and ta. 6. fig. 2 *] which ariſeth fleſhy from the lower part of the vpper iaw, where there is a kinde of aſperity or roughneſſe at the ſides of the chin: thence bending obliquely vpward and becomming broad (for it is broder and ſhorter then the former paire) are implanted into the middle of the lips, with whoſe skin as the former they are ſo mingled, that the Fibers do in a kinde of finger-fold cut betwixt one another.

Their vſe.

By the helpe of theſe Fibres the motions of the lippes become verie Diuers, ſo that *Galen* writeth in his 11. booke *de vſu partium*. and the ſecond *de Diſſec. Muſ.* that by theſe muſcles (which yet he would haue to be foure) there are eight ſeuerall motions effected, foure oblique two in each lip: and beſide them foure other right, two altogether right, either when the lips are furtheſt aſunder, the one yeelding vpward to the noſe, the other downward to the chin: or when the lips are cloſe ioyned, the vpper being drawn downward, and the lower vpward.

Eight ſeuerall motions by theſe muſcles

For as in the wreſt of the arme right motions are made by the confluence or concurrence of oblique motions, ſo is it alſo in the lips: for if the muſcle of either ſide do alone work, that motion is made ſide-long, but if both of them bee at once ſtretched, then ſhall the ſame lip be after one and the ſame manner drawne vpward by the vpper muſcles & downward by the lower. Thus *Galen* exemplifieth the vſe of theſe muſcles in the places laſt aboue named, to which he that deſires more ſatisfaction may haue recourſe, wee will follow our ſtory.

The Corrall of the Lippes

To theſe muſcles before deſcribed that fleſhy and rude lumpe [Ta. 7. fig: 3, C] and yet muſculous may be added, which in the circumference of the mouth maketh the lipsboth aboue and below, which by ſome is made a peculiar paire of muſcles of the face: we call it if you pleaſe the Corral of the lip. *Falopius* diuideth them into two muſcles, whereof one garniſheth the vpper lip, the other the lower: and he aſcribeth to them as to other muſcles their ſeuerall motions, gathering and wrinkling themſelues vp, and with them the fleſh of the lippes when we would make our mouthes little.

The Vſe of the Corrall.

CHAP.

CHAP. XV. *Of the Muscles of the lower Iaw.*

OF the two Iawes, the vpper as well in man as in all other creatures is immoueable, excepting the Parrot and the Crocodile, the lower is necessarily mooued for the breaking and preparing of our meate, and the articulation of the voyce. The motions of this lower iaw are of two kindes, simple and compound, the simple motions are sixe, and the compound but one. The sixe simple motions are vpward and downeward, to the right hand and to the left, foreward and backeward. The compound motion is made of the right and the left the forward and the backeward, whereby the iawe seemeth to bee carryed round. The motion vpward is performed by the temporall muscle, downeward by the Digastricke, to the right hand and to the left by the first grinder called *Maxillaris primus*: backward by the other *Maxillaris*, the muscle that striketh in the mouth forward by the fifth paire.

Only the Parrot and the Crocadile moueth the vpper iaw.

Sixe similar motions and what they are

The motion vpward and downeward is to bite, or to share or cut: the motion to the sides, whether it be to the right hand or to the left, forward or backeward is to grinde: for the meate falleth vpon the teeth of the lower iaw, as vpon the mooued stone of a Mill. For as in a Mill the weight of the vpper stone breaketh the corne vppon the lower so the meate is ground betweene the vpper teeth which resemble the fixed or immoueable stone of the Mill, and the lower teeth set in the lower iaw which resemble the moueable stone. And therefore these Muscles are called *Maxillares*, that is, the grinders, and because their act is called Mastication or chewing, therefore they are called *Masticatorij* or *Manserij*, that is, the chewers. Wherefore the Mouth is opened, shut and drawne in compasse by fiue muscles on either side. The first is called *Temporalis*, *Galen de dissect. musculorum*, or *Crotaphites* [tab. 6. fig. 1. and 2. tab. 4. fig. 9.] his circumference is noted by his fleshy part by a. a. couered yet with the *pericranium*, & the Membrane retracted or drawne backe at. b. We call it the Temple Muscle, because it is seated in the temples man is in the side of the head at the vpper and forepart of the Eare. This muscle is a bone and fleshy, and the largest of all the rest, filling all the cauity of the temple bones. It ariseth [tab. 6. fig. 2. a. a.] with a broade fleshy and semicircular beginning or originall from the first bone of the vpper iaw of the forehead, of the forepart of the scull, of the temples and *Sphenoides*, or wedge bone, and becomes by degrees more fleshy, & growes narrow vnder the yoke bone called *Jugale* which runneth vpon it and about it ouerthwart [tab. 6. fig. 2.] and to which it groweth a litle for better defence, and is inserted with a short neruous and exceeding strong Tendon to the sharpe [tab. 7. fig. 4. b.] processe of the lower iaw imbracing it very firmely with his large armes.

Fiue muscles are mouers.

The strength of this muscle (by which sometimes a man is able to bite a strong nail em vnder, and we haue known a man therwith to guide a great bell being rung to the height) is caused by his fibres; for all of them as it were from three parts of a circle runne vnto his center, which is to be obserued in the dilatation of the wounds of this part and must sometimes necessarily be made, as also because of the appositemations of these Muscles that the Chirurgion may know how to make incision according vnto the rectitude of his fibres, lest he wound them ouerthwart, their vse and action should perish, and the life saith *Columbus* with it.

A strange strength of a mans iaw.

A good obseruation for Chirurgions.

The vse of this Muscle together with his fellow is, if they draw directly vpward to lift vp the lower iaw to bind it strongly and to shut the mouth. But if one of them draw alone, then is the traction of the iaw oblique, although *Vesalius* thinketh that this oblique traction is made by three muscles, the temple muscle, the *masseter* or chewer and that that lies hid in the mouth; whence it is that some make three *masseters*, but *Hippocrates* in his booke *de Arte*, mentioned but two. This Muscle the Ancients and amongst them *Hippocrates* and *Galen* haue preferred before many others and admired in his composition the wisedome and prouidence of the Creator in making it diuersly according to the diuers vse of the creature.

Vesalius his opinion of the oblique traction of the iaw.

Galen also in his eleuenth booke of the vse of parts and the third chapter, sheweth how these muscles if they be wounded do especially bring conuulsions, feauers, deepe and dangerous sleepines, and light frenzies. And *Hippocrates* saith, that the wounds of the temples are mortall. The reason of these accidents may be because they are neare neighbours vnto the braine, there being onely the scull betweene, and that parted by the coronall sute or crown seame: as also because of the many and large Nerues which are disseminated through it as *Galen* hath obserued in the former Booke and the seuenth Chapter. This

Hyppocrates.

muscle hath 3. nerues on either side inserued into him: two from the third coniugation, and the third harder from the fift coniugation to giue him the greater strength: for the more nerues and the harder a muscle hath, the stronger it is to performe his action. No marueil therefore if vpon the wounding or concussion, conuulsion yea death it selfe doe follow.

The dangers of the falling of the Iaw.

And hence it is that *Hippocrates* though the luxation of the neather Iaw was oftentimes deadly, because thereby this Muscle is distended, and in his Booke *de articulis* hee sayth, that vnlesse the bones of the neather Iaw be ioynted againe after their luxation the life will be in great ieopardy, by reason of the continuall Feuers and dull and drowsie sleepinesse which follow thereupon: for these muscles if they be altered from their naturall disposition, and intended or streatched are *soporiferum*. Wherefore Nature for their better defence hath couered them first with a strong thicke and hard membrane, which is the *Pericranium* or scull-skinne, by reason whereof the muscle on the outside looketh liuid, for his inner part which cleaueth to the bone is altogether fleshy, because the bone in that place is not couered with the *Periostion*. And because a part of the *Pericranium* runneth ouer this Muscle, some haue described it with two tendons, one inward and another outward.

How nature hath defended these muscles.

The 2. defece

Another defence it hath is this, that the lower part which is neruous is walled with the Iugall or yoake-bone, that the nerues (sayth *Galen* in the 8. Chapter of his 9. Booke *de vsu partium*) should not be hurt, so as this bone seemeth to haue been made onely for the behoofe of this muscle.

The third.

Thirdly, the Tendon of this Muscle is defended aboue and below with flesh that it might be better secured from outward iniuries. The difference of these Muscles according to the variety of creatures is after this manner: First of all in men they are the least and least neruous ordinarily; among beasties they are the least in Apes, I meane according to their proportion. They are greatest and largest, as also most neruous in such beasts as haue their teeth set like a Saw, as Lyons, Wolues, Dogges and such like. There are other creatures wherein they are very large but not so neruous; large not so much for the strength of the action, because those great creatures doe feede most what vpon the earth, but that they might bee proportionable to the magnitude of the Iaw; such are Asses, Horses, Oxen, Camels and such like; as we may reade at large in *Galen* the seuenth Booke *de vsu partium* and the 2. Chapter.

In what creatures these muscles are greatest.

In what creatures least.

Why least in men.

They are least in men both because our neather Iaw in respect of other creatures is the very least, and beside, because our teeth are giuen vs only to breake our meate and for no other vse: for a mans fortitude consisteth not in the strength of his Iawes, neither doth hee thereby curbe and keepe in awe the other creatures but by reason and by his hands. Notwithstanding they are the greatest of all the muscles of the Iaw, because they almost sustaine it and lift it vp as if it hung and depended only vpon them.

The 2. muscle of the lower iaw called the grinders

The second Muscle of the lower Iaw is called *Manserius primus*, *Masseter & molitor*, names all taken from the vse of the Muscle which is called *Manducation* or chewing, and therefore wee may well call it in our English the Chewing or the grinding muscle. His position is in the Cheeke [tab. 6. fig. 2. and tab. 7. fig. 3. I ta. 4. fig. 2. V] and it hath a double head, one neruous proceeding from the ball of the cheeke [tab. 6. fig. 2. λ] vnto the sutura where the Iaw-bone meeteth with a part of the Iugall or yoake-bone, and passeth along vnto the vtmost angle of the Iaw which wee call his acute or sharpe processe; the other head is fleshy and passeth from the yoake-bone [ta. 6. fig. 2. κ and ta. 7. fig. 3. at *] toward the chinne, and is implanted very strongly [table 6. figu. 2. μ] with a broad insertion to the whole latitude of the lower Iaw, so as it representeth, saith *Galen* in the 4. chapter of his 11. Booke *de vsu partium*, the corner of a blunt or obtuse triangle, the top whereof is neare the ball of the cheek, [λ] one side toward the end of the yoake-bone [from λ to κ] another side toward the lower Iaw [from κ to μ], and the third and last as it were a Basis ioyneth both the forenamed sides to all the parts of the lower Iaw, being extended or streatched according to his length.

His fibres.

The Fibres of these heads do intersect themselues like this figure χ; and thence it is that they moue the Iaw as well on both sides as also forward and backeward (for there is a diuers motion required in chewing or grinding the meate) and in compasse: for as the vse and action of the temporall muscles was vehemently to ioyne the teeth & the two iawes together, and so to breake whatsoeuer should light between them: so the action of these

chewing

chewing or grinding muscles is to leuigate or shred small the meate that is before broken by the temporall muscles. To this action the tongue doth not a little helpe, which like a hand turneth and returneth the meate in the mouth that all his partes may come vnder the Breake; which motion of the tongue is performed by a muscle of the Tongue called *Lingua Masticator* or the Tongues Chewer, and not onely so, but also the muscles of the cheekes are of great vse toward the performance of the foresaid worke.

The third payre of muscles [Tab.7,fig.4. neere to ᵖ] is situate vnder the temporal muscle in the lower part of the cauity of the Temple bones, and taketh his beginning partlie from the vpper and vtter parts of the processes called *Aliformes* or like vnto wings which are sharpe and vnequall; and partly from the roofe and sharpe top or height of the bone called *Sphenoides* or the wedg-bone, which in the cauity of the temples looketh directlie against the yoke-bone, where it hangeth ouer a large rift made by the same *Sphenoides* & the greatest cheeke-bone. The 3. paire of muscles of the lower iaw

The originall or head of this muscle is partly neruous and partly fleshy, and hauing gotten this fleshinesse it is led obliquely backeward and is inserted into the necke of the lower iaw, and into the inside of his head. His vse is to moone and lift forward the Iaw, as the next that followeth mooueth it backeward.

The fourth muscle is another *Mansorius* which *Galen* in his fourth Booke of Anatomicall administrations the fourth Chapter and diuers other places, calleth the muscle lurking in the mouth, [Tab.7,fig.4 O] because it lyeth hid in the great bosome of the inside of the Iaw. This muscle is thicke and short, and ariseth very neruous from the inward cauity or hollow pipe of the wingy processes of the wedge-bone called *Sphenoides*; afterward becomming fleshy, large and thicke it descendeth with right fibres, and is inserted with a strong neruous and broad tendon to the inner and backe-part of the lower Iawe where the roughnesse is, and where the bosome or hollownes is fashioned that it might not take vp too much roome about the Almonds of the throate. And this muscle (sayth *Galen*) helpeth the temporall muscle to which it groweth strongly neere the production and insertion of his tendon; for it draweth the Iaw inward and vpward, and shutteth the mouth, because it is a matter of labour to draw a heauy thing vpward, and to breake and grinde a hard substance: besides when the Iaw is brought forward it draweth it backward againe. The 4. muscle of the lower Iaw.

The fift Muscle called *Graphioides* or *Digastricus*, double bellied [Table 7 figure 3, ᵒ and figure 3, ᴺ° Table 6. figure 2 °] is thinne and small, arising membranous and very broade from the Apendixe called *Styloides* (from whence *Galen* called it *Graphioides*, because the Ancients vsed to write vpon waxen Tables with a Probe which they called *Stylus*) and immediately becommeth fleshy and round and passeth vnder the lower part of the vpper Iaw and the eare, and in the middest where it is curued or crooked at the turning of the lower iaw it looseth his flesh and becommeth Neruous: and againe recouering his flesh is inserted into the middle of the iaw fast by the lower part of the chin, where the inner bone becommeth a little rugged for his better insertion, and where both the Muscles of each side do meete; albeit about his middest it cleaueth to the bone called *Hyoides*. There is also in this place a kinde of forme of a Pulley; for because these Muscles do not arise from the lower parts of the necke but rather from the vpper, they could not moue the Iaw downward vnlesse they had bene wound about the lower angle of the lower Iaw, as it were about a Pulley. The Fyfte and last muscle of the lower iaw His variable substance.

The vse of this paire of Muscles is to draw the Iaw downward, & so to open the mouth and by consequence to draw the tongue toward the throate: but if one of them onely do moue, it leadeth the Iaw obliquely to his owne side. It was called *Digastricus* because it hath two Venters or Bellies, being fleshy in the beginning and in the end, and in the middle [Tab.7.fig.3 betweene ° & ᵛ fig. 4. between ᴺ and °] neruous or tendinous (which is peculiar to this and to the second paire of muscles of the bone *Hyoides* [tab.7. fig:3, V, VI] and to the fift proper paire of the Larynx or throttle) partly for more strength, partly that it might not take vp too much roome because the place is but narrow, and there are many Instruments to fill it vp, especially the muscles of the tongue and of the *Hyois*: and therefore also they were made small and thin, round and long, their motion beeing but easie, for the Iaw fals downward with his owne weight, and therefore needed no strong retractor. The vse of these muscles together. What muscles haue 2 bellies

Finally, because a part of the square muscle (which with *Galen* we reckoned among the muscles of the cheekes) groweth more strongly to the bone of the lower Iawe, the right and The reason of *Arantius* his opinion.

and the left meeting at the middle of the chinne to draw the ſame downward; therefore
The vſe that *Arantius* limiteth. *Arantius* (who did not acknowledge the third paire aboue named) maketh it the fift paire of the Iaw, and ſayeth, that this portion or part of the ſquare muſcle together with the 4. paire called the *Digaſtricks*, do open the mouth and draw the Iaw downwards, yet ſo, that it is more directly drawne (without the motion of the cheekes) by the fourth paire; but by this fift paire as he accounteth them, the iaw is wreſted obliquely together with the cheeks and the lovver lip ſide-vvard if but one of them moue; if they mooue together, then it inclineth it to neither part but leeadeth it tovvard the throttle.

CHAP. XVI. *Of the Muſcles of the Choppes which ſerue for Diglutition or Swallowing.*

Galen firſt of all men deſcribed the muſcles of the Choppes, whome after *Oribaſius* his *Epitomizer* and *Auicen* followed, making one on each ſide. Among the later Anatomiſts *Faloptus* was the firſt who deſcribed three paires;
4. paire of muſcles of the chops. which are ſeated in the Mouth betweene the coat of the palate & the bredth of the Noſethrils. VVe will reckon vnto you 4. paire, whereof two doe dilate and tvvo contract; and therefore they helpe the Svvallow becauſe the Chops vvere of neceſsity to bee dilated or ſtraightned vvhen the meate and the drinke ſhould paſſe by them.

The firſt. The firſt paire ariſeth thinne and neruous from the toppe of the vvedge-bone called *Sphænoides* neare the articulation of the lovver iavv vvith the bone of the temple, and deſcendeth very ſmall and ſlender by the invvard cauity of the *Pterygoides*, and endeth in a neruous thinne and broad tendon vvhich paſſeth ouer the cleft vvhich is in the end of the *Pterygoides*, and being reflected is inſerted into the skinny part of the palate at vvhich the *Vuula* hangeth. If both theſe muſcles moue together they dravv the bottom of the chops, together vvith the *Vuula* vpvvard and forvvard; if but one of them moue, then it dravveth vnto that ſide vvherein it is ſeated.

The ſecond. The ſecond paire ariſeth neruous from the ſame beginning vvith the former, and declining dovvnevvards it is inſerted into the ſides of the choppes vvhere the Tonſils or Almonds doe reſide and taketh vppe or at leaſt embraceth all the ſide and backepart of the Choppes This payre draweth the Tonſils vpward and ſidelong, and dilateth the whole cauity of the Chops by parting them aſunder. Theſe two paires ſerue to dilate or open the Choppes, and ſome ſay they hinder the liquid matter that comes vp in vomiting that it paſſeth not through or into the noſe.

The third. The third paire compaſſeth the backeward and ſide cauitie of the Choppes, and ariſeth very thinne where the head is ioyned with the necke, whence it deſcendeth and is inſerted in the ſides of the bone *Hyois* and the firſt griſtle of the Throttle, ſometimes alſo into the roote of the Tongue but obſcurely; and it conſtringeth the Choppes when a man ſwalloweth; and as *Faloptus* perſwades himſelfe it helpeth to ſwallow *a great morſell*; becauſe in diglutition or ſwallowing of meat it raiſeth vp the throttle.

The fourth. The fourth paire ariſeth very ſlender from the inſide of the appendix called *Styloides*, declineth forward, and is inſerted with a membranous Tendon to the firſt Griſtle of the *Larynx* or Throttle, to the ſides of the bone *Hyois*, and the extremity of the rootes of the Tongue: and therfore (ſayth *Platerus*) it may be ſayd to be a paire common to the chops and to the Tongue, becauſe it draweth the tongue and the foreſayde parts backwards and vpward, and conſtringeth the choppes as wee ſwallow. Theſe two latter paire doe contract the choppes and ſomewhat lift vp the throttle that the ſwallow might bee the more facile and eaſie.

CHAP. XVII. *Of the Muſcles of the Bone called Hyois.*

BEcauſe the meate when it is broken by both the Iawes and their Teeth, by the helpe of the Muſcles of the Cheekes, the lower Iaw and the Tongue, muſt bee ſwallowed and tranſmitted into the Stomack; and that this diglutition or ſwallowing is a voluntary motion, it had neede of Muſcles appropriated thereunto and diſtinct from the muſcles of the Tongue, becauſe wee can ſwallow and yet hould our tongues ſtill and ſtedfaſt: and beſide, the muſcles of the Tongue doe accompliſh other priuate motions of their owne.

Theſe Muſcles which ſerue for diglutition they make to be proper to the bone *Hyois*, both

both becauſe they are annexed vnto it, and do alſo mooue it vpward and downward, and to both ſides; for the bone it ſelfe was neceſſarily to be mouable, becauſe it was ordained to be helpeful to deglutition. But there are two kinds of muſcles which are ioyned to this bone: ſom haue their original frō it but do ſerue other parts, as the tongue & the Larynx. Others that take their originall from other bones, and yet are inſerted into this *Hyois* and are proper to it, and of theſe we will intreate at this time, reckoning vp vnto you 4 payre although there be ſome who account ſixe. Foure paire of Muſcles.

Of theſe two, paire are numbred with the muſcles of the tongue, becauſe the motions of the tongue and of the bone Hyois are very nere a kin, and therefore it is no wonder if their muſcles be mixed and connected together.

The firſt paire run betweene the breſt-bone and the bone *Hyois*, and are therefore called *Sternohyoidei* [Tab. 6. fig. 2 ς ª] and appeare outwardly vnder the skin lying vppon the ſharpe artery and the griſtle of the throttle called *Thyroeides*. It ariſeth with a broad and fleſhy beginning from the vpper and inner ſide of the breſt-bone, and runnes directly vpward, and is implanted very fleſhy without a tendon (ſaith *Columbus*) into the foreſide of the baſis of the bone *Hyois*. All along their paſſage they are fleſhy and broad, and are diuided in the middeſt by a line which paſſeth according to their length. Their vſe is to draw the bone ſtraight downward and backward, and by accident alſo they defend the throtle and the griſtle *Thyroeides*. The 1. paire.

The ſecond paire called *Genio-hyoides* [Tab. 6. fig. 2 S] are vnder the chinne, and the fift paire of the lower iaw. [Tab. 6. fig. 2 O] They are large and ſhort and fleſhy all ouer, and do ariſe with Fibres of a diuers courſe from the inner part of the lower iawe, and are inſerted with the ſame breadth into the middle part of the bone Hyois, into which alſo the firſt paire was implanted. They draw directly vpward and ſomewhat forward. The 2. payre.

The third paire called *Stylocerato-eidei* [Tab. 7. fig. 2 ᵀ] is ſeated obliquely and vnder the Chin as the former, and are outwardly ſtretched vppon the fifte paire of the neather law. They are ſlender and round, and ariſe from the roote of the Appendixe *Styloides* aboue the originall of the fift muſcle of the law, and end into the hornes of the *Hyois*, that is, into the laterall or ſide parts thereof, and they are ſometimes perforated in the middeſt to giue way to the muſcle which openeth the Iaw. They moue the bone toward the ſides and ſomewhat vpward. The 3. paire.

The fourth paire is called *Coracohyoeidei*. [Tab. 6. fig. 2. V, V. Tab. 7, fig. 3, V, V] They ly lurking vnder the fourth muſcle of the ſhoulder-blade, as *Veſalius* and *Platerus* haue noted. They are ſlender and long, and do ariſe out of the proceſſe called *Coracoeides* at the vpper end of the ſhoulder-blade nere his necke, and do run obliquely vpwarde vnder the ſeuenth muſcle of the head, and are implanted where the third paire is, into the beginning of the lower proceſſe of the bone *Hyois*, and theſe draw downward vnto the ſides. This is a long paire on eyther ſide fleſhy and hath a double belly, and therefore *Galen* cald them *Digaſtricks*, but in the middle they are ſlender and nerious as is the fourth muſcle of the law and the fift proper muſcle of the Larynx, and extenuated into the forme almoſt of a Tendon, haply to giue way to the ſeuenth muſcle of the head, which heere runneth ouer him [K] as to his better. The 4. paire.

Concerning the vſe of theſe muſcles, we craue leaue to add yet a little more: ſome thinke they were not ordained for motion but rather for tenſion, to tye, eſtabliſh & ſuſpend the bone *Hyoides*, ſo ſaith *Laurentius*: others as *Archangelus* thinke, they ſerue for deglutition, and that they are the proper muſcles of the *Hyois*. Others as *Arantius*, becauſe this bone is the baſis of the Tongue, and becauſe the baſis of any thing can by no meanes be mooued, but that alſo muſt be moued which is eſtabliſhed vpon that baſis, do thence determine that theſe muſcles do mooue the Tongue, and ſo much the rather becauſe the manifold and frequent motions of the Tongue can hardly be imagined to be accompliſhed by ſo few and ſo ſmall muſcles as determine or end in the ſubſtance of the Tongue. Wherefore theſe may be called the common Muſcles of the tongue and the *Hyois*, into which certaine Nerues are diſtributed from the ſixt Coniugation. An additiō concerning the Vſe of theſe muſcles *Laurentius*. *Archangelus*. *Arantius*.

CHAP. XVIII. *Of the Muſcles of the Tongue.*

THe tongue hath three ends in Nature; to ſpeake, to taſte, and to rowle the meate in the mouth, which cannot bee performed without motion, and therefore Nature hath allotted vnto it Muſcles, which from thoſe three actions may bee called, the Three vſes of the tongue.

Talkers, the *Taſters*, and the *Rowlers* of meate. In man the eſpeciall end of the creation of the tong and of the motion of the ſame is for ſpeech, as in beaſts for taſt.

The eſpeciall vſe in man.

For becauſe they want hands wherwith to reach their meat or fother vnto their taſt, it was neceſſary they ſhould be able with their tongues to lick and gather it of the earth: but man is able to taſt without the motion of the tong, becauſe he hath hands wherewith to bring that he would taſt vnto the inſtrument or organ of the ſence: but both of them haue neceſſary vſe of it in rowling and returning the meat againe vnto the teeth which falleth from them into the ſpace of the mouth.

VVherefore that it might anſwer thoſe intentions, it was made moueable and had therfore muſcles, and not muſcles onely, but alſo a figure fit for motion, ſome parts being thinner then other: yet becauſe it ſhould not moue beyond his teather; Nature hath reſtramed it with a ligament, that the body of it which by reaſon of the diuers fibres it had was infinitely diſpoſed to motion and agitation, might rowle vpon that axle tree, or turne vpon thoſe hinges onely: but of theſe things we haue ſpoken ſufficiendy heretofore, excepting of the muſcles whoſe proper place this is.

The bridle of the tongue.

The Muſcles therefore of the Tongue are double, ſome are common, others proper. Thoſe are eſteemed to be common, which haue already bene ſaid to belong to the bone *Hyois*, vnto which the third paire alſo now to be mentioned may happily be referred: and thoſe proper which hauing their original other where, do determine and end in the ſubſtance of the Tongue.

Muſcles of the tong double.

The firſt paire are called *Styloglóſſi* or the Auger-tongue Muſcles [Tab. 8. fig. 1 & 2] *Galen diſſect. muſcul.* 14 calleth them πλάγιοι, that is tranſuerſe. They haue ſlender originals from the vtter face of the Appendix *Styloeides* (as the fourth paire of the throat from the inſide of it) and are implanted with tranſuerſe fibres into both ſides of the Tongue about the middle thereof, yea they proceede forward and attaine vnto the top of the Tongue; and when the Tongue is lilled out they draw it in againe. But becauſe their Fibres are ſo wouen one within another, when both of them are at once contracted toward their originall they lift the tongue directly vpward, but when one of them onely worketh then is the tongue lead vpward to one ſide onely.

The 1. paire.

[*Tab. 8. is the ſame with that in lib. 8. Fol. 643.*]

The ſecond paire are called *Myloglóſſi* or the *grinder-tongue* Muſcles [tab. 8. fig. 1. and 2.ᵇ.] They ariſe with abroad and inuerted originall and tranſuerſe fibres from the ſides of the lower iaw neare the roots of the grinding teeth called *molares*; and are inſerted on both ſides into the length of the ligament which is vnder the baſis or foundation of the tongue, and degenerateth into the bridle by which the tong is tyed to the Chops. When one of theſe workes we turne the tongue vpward and obliquely, but when both of them mooue, then the tip is directly lifted vpward to the palate and vpper teeth. Sometimes this paire doubleth the tongue or maketh it hollow like a gutter, and ſuſtaineth it ſo in forme of a compaſſed bow to the palate with the aſſiſtance of the ligament and bridle becoming ſomewhat rigide or ſtiffe. And if the ſecond paire belonging to the bone *Hyois* doe worke with them, then the tongue becommeth more narrow and ſolid and is exerted or thruſted forth to his extent beyond the lips.

The 2. paire

The third paire are called *Genuogloſſi* or the *chin-tongue* Muſcles [tab. 8. fig. 1. and 2.ᶜ.] They ariſe with a narrow beginning from an aſperitie or roughnes in the inſide of the middeſt of the Chin; afterward they become broader and repleniſhed with right fibres, & are implanted into the middle of the tong the greateſt part of them at the roote, yet ſome part of them runs out toward the tip, ſo that the diuers parts of the ſame Muſcle do worke contrarily. For the greateſt part of their fibres beeing drawne toward their originall thruſt the tongue beyond the teeth and the lippes, (although *Auerrhoes* thought that a proper motion of the tongue) the leſſer part in their action draw it againe inward. Sometimes they communicate ſome fibres to the bone *Hyois* which they ſo draw vnto the chin. They haue alſo certaine lines in them which Anatomiſts call *inſcriptions* as if they were many Muſcles.

The 3. paire.

Their contrarie vſes.

The fourth paire are called *Baſigloſſi* or *Ypſigloſſi* or *bone-tongue* Muſcles. [tab. 8. fig. 1. and 2.ᵈ.ᵉ.] Theſe doe ariſe ſtraight fleſhy from the vpper and middle part of the bone *Hyois* and in ſome places are obſcurely diuided aſunder, as if they were many muſcles, and ſo run a long the length of the tongue, and are inſerted in the middeſt of it. Their vſe is when they are contracted to draw the tongue directly inward or backward toward his roots.

The 4 paire.

The

The fifth paire are called *Ceratogloſſi* or *horne-tongue* Muſcles [tab.8.fig.1. and 2.*] and ariſe from the vpper hornes (if they be there) of the bone *Hyois*, from whence paſsing somewhat obliquely or ſloping they are inſerted into the ſides of the tongue neare vnto his roote; ſometimes they ariſe from the neather hornes when the vpper are wanting, or are not very bony, but rather like ligaments; which as wee haue ſayd is moſt commonly in women which haply makes their tongues more plyable. If one of theſe onely be contracted the tongue, eſpecially the roote of it, is drawne ſide-long downeward, and ſo it may bee ſayd to moone to the right ſide or to the left: but if both of them be contracted then is it moued right downeward toward the throate; this paire in Oxen is double, in men it is but ſingle. The 5. paire.

Theſe fiue paire of Muſcles therefore do moue the tongue vpward, downeward, foreward, backeward, on the right hand and on the left hand, or to the ſides; but if they worke ſucceſſively, that is, one vpon another, then they turne the tongue round; & all theſe motions the muſcles of the bone *Hyois* do not a little further, which ſome do rather aſcribe to the fibrous ſubſtance of the Tongue, which hath indeed all three kindes of fibres. The ſubſtance of the Toung.

At the roote of the Tongue when theſe Muſcles are remoued there appeareth a certaine fleſh compounded of many Glandules mingled with fat, which fleſh doeth not merrit the name of a muſcle, becauſe a Muſcle doeth not conſiſt of glandules or kernelles but of fleſhy fibres. [tab.8.fig.1. and 2.*] This knot of glandules groweth at the roote of the Tongue that with their liquor it might alwaies bee kept moyſte, becauſe without moyſture there can be no perfect taſte, no more then there can be any concoction in the Stomack without Elixation or boyling; for the concoction of the Stomacke is not a roaſting but a boyling or elixation; & therefore Nature hath ordained the Glandulous *Pancreas* or Sweet-bread to touch the Stomacke, that thence there might continually aſcend moyſt vapours that the concoction of the ſtomacke might be accompliſhed by a moyſte boyling, not by a dry roaſting. The glandulous fleſh at the roote.

Moreouer, this moyſture of the kernelly fleſh maketh the motion of the Toung more glib and glad as wee ſay; or nimble; for when the Tongue is dry (as vvee may perceiue in thoſe that are exceedingly a thirſt) his motions are more ſlovv; the ſame alſo vvee haue experience of in thoſe that labour of burning Agues, in vvhome all the moyſture of the Tongue is exhauſted and dryed vp. Moreouer, the Almonds of the Throate which we call *Tonſillæ*, as is before obſerued by yeilding a perpetuall moyſture, doe moiſten the Tongue and ſo further his motion.

CHAP. XIX. *Of the Muſcles of the Larynx or Throttle.*

BEcauſe the actions of the Throttle or *Larynx* are performed with voluntary motion, Nature hath giuen it muſcles, which by their action which is Contraction might bend, extend and moue ſidelong the ioynts of the griſtles, that ſo the *glottis* or Toung-let might become mouable and his cleft might be made broader or narrower as need ſhould require: for ſo it behoued to be, becauſe it was conuenient that our voice as well as our ſpeach ſhould be at our commaund. The Throttle therefore hath two kindes of Muſcles, Common and Proper. The Common are ſixe, (or three paire) of which foure doe conſtringe and two do dilate it. The Common are ſo called becauſe they ariſe from other partes, and are but implanted into the Throttle; and of theſe wee will treate firſt, becauſe they firſt fall vnder our view and ſo come firſt to be ſhewen. The action of a muſcle is Contraction. 3. paire of common.

The firſt paire of the common Muſcles [tab.9.fig.7.xx] which *Veſalius* and diuers others do make the ſecond, is ſituated in the forepart of the Throttle, one on each ſide, and we call them *Bronchios* or the weazon Muſcles, becauſe they cleaue to the rough artery all along, which is called βρόγχος by *Hippocrates*. For they ariſe with a fleſhy and broade beginning from the vpper and inner part of the Breaſt-bone at the very *Iugulum* aboue the clauicles, and with right fibres doe runne vp along the weazon fleſhy and a little broader then where they aroſe, & are inſerted into the ſides of the ſhield-griſtle called *Thyroeis*, below neare the Glandules with a broade and fleſhy Tendon; which in man is but one, but in beaſts it is deuided in the middeſt, & in moſt of them one part is faſtned into the throttle, the other into the bone *Hyois*. Yet *Galen* is of opinion that this is their originall, and that they are inſerted into the breſt-bone. The firſt paire.

They are very long, becauſe not the ſhield-griſtle or the *Thyroides* only, but the whole

Larynx

Larynx is moued eſpecially in a baſe voice, where the throttle mooueth downeward, and the whole weazon is contracted in his membranous diſtances, and therefore it was, that this paire cleaueth to the whole length of it.

They are moreouer very ſlender, becauſe the throttle eaſily deſcending with his own waight did not require any great ſtrength: yet notwithſtanding they haue certaine inſcriptions or neruous diſtinctions, ſuch as are in the right muſcles of the paunch, by which their length and tenuity is ſecured from danger.

Their vſe is to draw down the ſhield-griſtle called *Thyroides*, and below to conſtringe or contract it, and ſo to dilate the cleft or fiſſure of the *glottis* or toung-let in a baſe voice; they alſo doe ſomewhat contract the weazon, that it be not doubled when wee ſpeake, or the throttle too much dilated aboue.

The 2. paire. The ſecond paire of Common muſcles [ta. 9. fig. 3. h] which *Veſalius* cals the firſt paire as alſo doth *Falopius* and ſome others; is ſituated likewiſe in the forepart of the *Larynx* or throttle, and are called *Hyoeides*, or rather *Hyothyroeides* or the ſhield-bone muſcles, theſe are oppoſed to the former and are farre ſhorter. They ariſe broad and fleſhy almoſt from all the lower part of the bone *Hyois*, to whoſe inward ſides they ſeeme to be continuated; and with right fibres they creepe downeward together, ſauing that their inner ſides doe depart one from another, and are each of them implanted with a broad and oblique end into the lower part of the Griſtle *Thyroeides* which they wholly couer. Their vſe is to dilate the lower part of the ſhield-griſtle and to contract his vpper, & by drawing the throttle vpward to make the cleft ſhorter and narrower; ſo we may perceiue that in an acute or ſhrill voice the throttle moueth vpward; but if this muſcle doe proceede obliquely backward as often it doth, then it mooueth the ſhield-griſtle or *Thyroeis* vpward and forward. I can giue no better reaſon of their ſhortneſſe, but becauſe the Larynx hath other helpes to draw it vpward beſide theſe: for the bone *Hyois* being mooued vpward by other Muſcles, draweth the whole throttle vpward with it.

Tab. 9. The ſame with the xv. Lib. 8. Fol. 635.

The 3 paire. The third paire of common Muſcles [Tabl. 9. fig. 7 [11]] are ſeated in the backe part of the Larynx, they are called *œſophagæi* or the Gullet muſcles, and truely ſome thinke they are muſcles of the *œſophagus* or Gullet and not of the Throttle or Larynx, becauſe they encompaſſe the gullet on euery ſide and are thought to helpe much indigluti tion. They *Laurentius.* are altogether fleſhy and large, and do eſpecially lye vpon the vpper part of the Gullet, which they encompaſſe ſaith *Galen* like a ſphincter, three fingers bredth ouerthwart, and do almoſt cleaue vnto it.

They ariſe from the ſides of the Shield-griſtle or *Thyroïs* all along, where there appeareth a rough line, and paſſe aboue the gullet with their Fibres almoſt tranſuerſe, and there in their extremities or ends they meet, yet ſo that they are diſtinguiſhed by a white line running through their length, eſpecially in beaſtes, for in a man it is oftentimes not viſible, & beſide the Fibres do not ſeeme to be diuided, ſo as they may eaſily be taken for one muſcle. Their vſe is, as they contract the ſides of the Shield-griſtle or of the *Thyroïs*, ſo to compreſſe it to binde and ſtreighten the cleft; but as they encompaſſe the gullet & are drawne into themſelues, ſo by a voluntary motion they helpe the ſwallowe, and are ſomewhat aſſiſtant to the naturall Faculty as we haue partly opened before. And thus much of the common muſcles of the throttle, now follow his proper.

Proper Muſcles. Of proper muſcles there are ten (or fiue paire) ſixe of them do dilate, and foure contract; they are called *Proper*, becauſe they both ariſe from the Larinx to which they grow, and againe are inſerted into it, imploying all their ſeruice to it alone, opening the cleft in inſpirations or when we take in breath, and ſhutting it when we breath out; beſides they faſten together the two Cartilages or griſtles, which do originally and of themſelues helpe the forming of the voyce. Of theſe muſcles ſome are before, ſome behinde, others without others are placed within.

The 1. paire The firſt paire of the proper [tab. 9. fig 4. [f] but in the ſixth figure one of them is ſeparated, the other remaineth in his place,] which are forward and vttermoſt we cal *Antici Crycothyroïdei* or the forward *Ring-ſhield* muſcles: their ſituation is in the lower and forepart of the Originall. Larynx, they ariſe from the Cartilage cald *Crycois* or the Ring fleſhy (but ſmall and hauing oblique fibres) & proceed obliquly til they be implanted into the Baſis of the ſhield-griſtle or *Thyroeides* withinward, & in their whol progreſſe (their middle part only excepted) they are fleſhy

fleſhy and broade: and if you ſeperate the lower proceſſe of the ſhield-griſtle or *Thyroides* from *Crycoides* or the Ring and follow it with a ſection, you ſhal perceiue that there is one in each part.

The vſe of theſe is to moue the *Thyroides* from aboue downward, to ioyn it to the *Crycoides*, to conſtringe the lower part of *Thyroides* and to dilate the vpper part, and by that meanes to open the *glottis* or cleft of the *Larynx*.

The ſecond paire are called *Crycoarythenoidei poſtici*, the backeward Ring-Ewer muſcles. [tab.9.fig.5.f] Their ſituation is in the backſide of the Ring-griſtle and they ariſe narrow and fleſhy from the lower and backe partes of the ſame griſtle, and running vpward [ta.9.fig.5.f] do fill a ſmooth cauity made for their ſake in the backſide of the Ring-griſtle which looketh toward the Gullet or *Oeſophagus*; and at length becomming more large & ſtrong with fibres ſomewhat ſloping or oblique, they fall from the ſpine or rough line of the Ring-griſtle, and are inſerted on both ſides neruous into the lower part of the Ewer-griſtle where it is articulated with the Ring-griſtle. The 2 paire.

The vſe of theſe is to turne the third Griſtle backeward to the outſide of the *Larinx*, to open the cleft and dilate it to the ſides, and ſo they further the baſe voice. But as they haue both right and oblique fibres, ſo they ſerue for diuers and mixed motions; with the right they draw the cleft backeward and ſo open it; with the oblique they helpe to moue toward the ſides; ſo that they open and enlarge the cleft both in the length and in the bredth of it. The vſe of their double fibres.

The third paire are called *Crycoarthenoidei laterales* or the ſide Ring-ewer muſcles. [tab 9.fig.4. r.] Their originall is fleſhy from the Ring-griſtle where it is brodeſt, from whence they proceede directly vpward, and become larger and more fleſhy, & are inſerted to the ſides of the Ewer-griſtle at the articulation or ioynt, and do occupy all the roote of the third griſtle which the former paire do not touch. The 3. paire.

Their office is outwardly to ſunder the double Ewer-griſtles, and to ſeparate them one from another ſo much as the fifth paire drawes them together, and by that meanes they driue out the ſides of the cleft and open the throtle. But becauſe theſe muſcles are ſeated, partly without, and partly within the capacitie, happily on the outſide they binde or contract the Larinx.

The fourth paire called *Thyroidei interni*, the inward ſhield-griſtle, or *Thyroarythenoidei*, that is, the ſhield-ewer muſcles, [tab.9.fig.4.ee.tab.8.fig.1.ee.] are broade, fleſhy, and haue diuers fibres mingled and vnited together, and in their beginning three inſcriptions or diſtinctions as if they were three ſeuerall muſcles, and are ſeated ouerthwartwiſe, in the capacitie of the Larinx or throtle. They ariſe cloſe one to the other from the inner, hollow and middle part of the ſhield-griſtle (whoſe inward cauity they fil) along the whole length of it, and with oblique fibres they aſcend vpward, growing narrower in the aſcent, and are inſerted into the ſides of the ewer-griſtle which forme the rongue-let or *glottis* following the ſides of the cleft. The 4. paire.

Theſe are the largeſt and ſtrongeſt of all the proper Muſcles and almoſt equall all the Muſcles of the throttle put together, and that for good reaſon, namely becauſe in the retaining of the breath they were to reſiſt all the Muſcles of the Cheſt. For in drawing the parts of the Ewre-griſtle vnto the Shield-griſtle, and in conſtringing them or gathering them together and thruſting the tongue-let forward, they ſhut it vp and are ſaid to cloſe the throtle. If in theſe Muſcles there happen an inflamation it bringeth a mortal ſquinnacy there appearing no redneſſe neyther in the chops, nor in the mouth, nor in the necke. For in the ſquinſie ſometimes the breſt-bone, ſometimes the necke looke red; the breſt-bone becauſe of the continuity of the weazon muſcles, which wee ſaide did ariſe fleſhy from the vpper and inner ſide of the breſt-bone and ran all along the weazon, and were inſerted into the Shield-griſtle. The true and dangerous ſquinanie.

The ſides of the necke become red, becauſe of the Gullet Muſcles which ariſing from the ſides of the Shield-griſtle doe encompaſſe the whole gullet like a ſphincter: alſo the fore and vpper part of the neck looketh red, becauſe of the continuity of the Shield-bone Muſcles which ariſing from the bone *Hyois* are inſerted into the lower part of the Shield-griſtle couering the ſame wholie.

The fift and laſt paire called *Arytenoidei* or the Ewre-Muſcles [Tab.9.fig.4 and 5 e] are ſcituated outward and backeward aboue the griſtle where it reſembleth the figure of an Ewre or Water-ſpout, and where the gullet is ioyned to the throttle, and the third griſtle The 5. paire.

ſtle is articulated with the ſecond. They ariſe from the backe line or ſpine of the Ewer-griſtle, and doe runne vp with oblique fibres to the middle thereof, and where the two parts of the griſtle are tyed together they alſo are ioyned and inſerted. Theſe are ſmall, *Columbus* and *Archangelus* ſay they be the leaſt in the whole body: on the one ſide they bunch out like peares, but within they grow to the griſtle, in the midſt where they ioyne they are broader and thicker, as alſo where the white line appeareth, and ſeeme to grow into one in a common Tendon, then they become neruous for more ſtrength that they might not be indangered in their perpetuall motion, eſpecially when we hold our winde vpon occaſion long; and therefore ſome haue accounted them for one muſcle, ſome for two; and becauſe they are on either ſide fleſhy they are to be numbred among thoſe that haue their Tendon in the middeſt, as is the fifth muſcle of the lower iaw called therefore *Digaſtricus* or double bellied, and alſo the fourth paire of the bone *Hyois*.

The vſe of theſe muſcles is to moue the ewer-griſtle ſidelong to the right hand and to the left; yea to conſtringe or knit the baſis or foundation of the ſame, to draw both his parts together, to preſſe them one to the other, and ſo to ſtraighten and cloſe the cleft; whereby it is manifeſt that this third griſtle was neceſſarily made double, for if it had bene ſingle it could not haue beene ſtraightned by theſe muſcles nor ſhut by the fourth paire, nor opened by the ſecond and the the third paires. Moreouer theſe inward muſcles being inflamed the moſt acute and ſharpe Squinaſie is ingendred: for when they ſwell, by reaſon of the aboundance of the matter the outgate of the breath is hindered, and ſo the patient inſtantly ſuffocated, which wee haue knowne in the hundreds of Eſſex to happen within twelue houres after the diſeaſe began.

Why the Ewer-griſtle muſt be double.

The moſt acute ſquinaſie

The vſe of the muſcles of the Larinx or throttle as well common as proper, is to moue the griſtles thereof with voluntary motion to the infinite modulations or diuers accents of the voyce: ſo that when part thereof, eſpecially the vpper, is fitly dilated & ſtraightned, or opened and ſhut; the cleft of it (which is the proper and immediate organ of the voyce) might be either dilated for a baſe, or ſtreightned for making an acute or ſhril ſound which verily the common muſcles doe more manifeſtly, and the proper more obſcurely. Theſe muſcles are altogether diuers from the muſcles of the bone *Hyois*, and of the tongue: for if when they be at reſt, you put your hand to your Larynx and offer to ſing in baſe tunes, you ſhall perceiue the throttle to deſcend downewatd, and in ſhrill and treble you ſhall manifeſtly perceiue it to aſcend vpwards.

The vſe of all the muſcles of the throttle.

How they differ from the muſcles of *Hyois* and the tongue.

CHAP. XX. *Of the muſcles of the Epyglottis or the ouer-tongue.*

Galen is of opinion that the motion of the *Epyglottis* or ouer-tongue is in a man not voluntary but naturall, or at leaſt hee leaueth it doubtfull whether it haue any muſcles or no *Veſalius*, *Platerus*, *Columbus* and *Laurentius* thinke and reſolue there are none, yet *Platerus* maketh queſtion whether they be not found in ſuch men as doe eaſily vomit. Of the ſame opinion alſo is *Bauhinus*, *Aquapendens* thinketh the motion of it voluntary & performed by membranous muſcles. For my owne part I dare not ſtickle in ſo nice a queſtion. In beaſts that chew the cud they all acknowledge that it hath muſcles, thoſe we will briefly deſcribe for the helpe of young Anatomiſts who do often in the want of mens bodyes diſſect the throttles of Oxen or Sheepe to practiſe themſelues.

Diuers opinions of the *Epiglottis*.

There are therefore in beaſts 2. paire of muſcles belonging to the *Epyglottis* or ouer-tong, the firſt are called *Hyoglotti*, or the bone-tong, the ſecond the Ewer-tongue muſcles.

In beaſts two paire.

The *Hyoglotti* or bone-tongue muſcles are ſeated in the backe of the ouer-tong, they ariſe from the middeſt of the inner part of the bone *Hyois*, and are inſerted on either ſide into the Baſis of the *Epiglottis* neare his middle. They raiſe vp the ouer tongue after it is depreſſed in the ſwallowing of meate and drinke, to make free paſſage for expiration which otherwiſe would by it be intercepted.

The 1. paire.

The Ewer-tongue muſcles becauſe of the largneſſe of the Larinx or throttle are moſt euident in oxen. They ariſe fleſhy from the vpper part of the Ewer-griſtle at his articulation. At their originall they are contiguous or touch one another, and for a great ſpace ſeeme vnited and mingled, and runne a long courſe keeping their proportion through the inſide of the Shield-griſtle, & at length retaining their vnition or coniunction are inſerted into the inner Baſis of the Epyglottis or ouer-tongue.

The 2. paire

CHAP.

CHAP. XXI. *Of the Muscles which moone the head.*

THe head is mooued primarily or secondarily. Primarily aboue the second rack-bone of the Necke or aboue the first: aboue the second either bending forward or extending backward, aboue the first it is mooued as a Naue vpon an Axletree, or rather as the Poyse of a Watch vpon his Bridge. All these motions are performed by seuen or rather by nine proper paire, (*Vesalius* in his *Obseruations* accounteth ten) of which are *Extenders* and *Compassers* & are situated on the back part in the neck; & two *Benders* which are placed in the forepart of the necke. The head is mooued secondarily and by accidence when it followeth the motion of the necke: the muscles therefore of the necke moone the head but onely vnto the sides. For if the necke be not mooued, wee cannot incline the heade at all to the Shoulders. Nine paire of Muscles.

The first paire are called *Splenij* or the splinters, because they are very like the rowled splints which Chyrurgeons vse when bones are broken. [ꝛ. 10. ∆ ∆, their original is marked with 8. their insertion is with 9.] They are long and thicke, and on both sides rest vpon the rack-bones, and albeit they are very fleshy yet at their original from the fiue vpper rack-bones of the Chest (for they rarely reach vnto the fixt) they are sinewy. From thence they ascend vpward and grow fleshy receiuing a new original from the Ligaments of the rack-bones of the necke; some thinke they arise onely from hence, some from both places, howsoeuer their ascent to the head is not direct but somewhat oblique, & from that part of them which proceedeth out of the spines of the chest are produced two membranous Tendons which are inserted into the transuerse processes of the first and third *Ver-* The 1 paire. Originall double.

TABVLA X.

Table x. Wherein some Muscles of the heade, the chest, the arme, & the shoulder blade are described.

I, The processe of the shoulder blade, called the top of the shoulder.

O, the fourth Muscle of the arme or *the greater round Muscle* to which *Fallopius* his right muscle is adioyned, which some cal the *lesser round muscle.*

QQ, the fixt muscle of the arme or the vper *blade-rider.* X, the 2 muscle of the shoulderblade or the *Leuator* or *leaner.*

Z, the second muscle of the Chest or the *greater Saw* muscle.

Y, the fift muscle of the chest or the muscle called *Sacrolumbus.*

ε, β. His place wherein it cleaueth fast to the longest muscle of the backe.

γγ, the tendons of this muscle obliquely inserted into the ribs.

ΔΔ, the first paire of the muscles of the heade or of the Splinters.

Ch. 8, 9. their legth whose beginning at 8 & insertion at 9.

10, 11, the sides of this Muscle.

12, that distance where they depart one from the other.

13, the two muscles called *Complexi*, neare their insertion.

9, the second muscle of the backe or the *Longest* muscle.

Ω, the fourth muscle of the backe or the *Semi spinatus.*

A, the shoulder blade bare.

p, A part of the transuerse muscle of the *Abdomen.*

tebra

tebræ of the necke, or sometimes of the second, third and fourth, *Laurentius* will haue them to haue a double insertion; one part of them into the transuerse processes of the second Racke-bone, another part into the *Occipitium* of the head toward the sides of the *Labdall* suture, and thither I am sure their fleshy part reacheth. For they are nerueous in the Chest, and fleshy from thence forward, their fibres running obliquely vpward from the spine of the lower to the transuerse processes of the vpper racke-bones, all of them of length determining in the Nowle: yet *Columbus* sayeth they are right as long as the two muscles ioyne, and become oblique but after their diuision. For where they arise at the spine of the Chest they make a sharpe nooke or angle which is dilated as they ascend, and about the third Racke-bone of the necke the right is seuered from the left with a notable distance [tab. 10. character 12.] so as the space betweene them resembleth a triangle [tab. 10. char. 9. 10. 12.]

Their Implantation is broade and fleshy into the Nowle [tab. 10. from 11. to 9.] and so they haue three sides: one from their beginning to their parting asunder; the second from thence to the Nowle; the third from the nowle backe to their originall. *Falopius* hath obserued that sometimes they are inserted with a nerueous particle into the processe called *Mammillaris* or the Teat-like processe.

The vse of this paire is when they both moue, to draw and extend the head directly backeward: but when one of them onely worketh, then they turne the head to the side, and the right moueth somewhat backward saith *Archangelus*.

The 2. paire. The second paire are called *Complexi* [12. 11.] or the brayded Muscles, because they are wouen and brayed together with the third and fourth Muscles of the necke like a flat poynt wouen of diuers threds, or else because of the diuers formes. For their origi-

TABVLA XI.

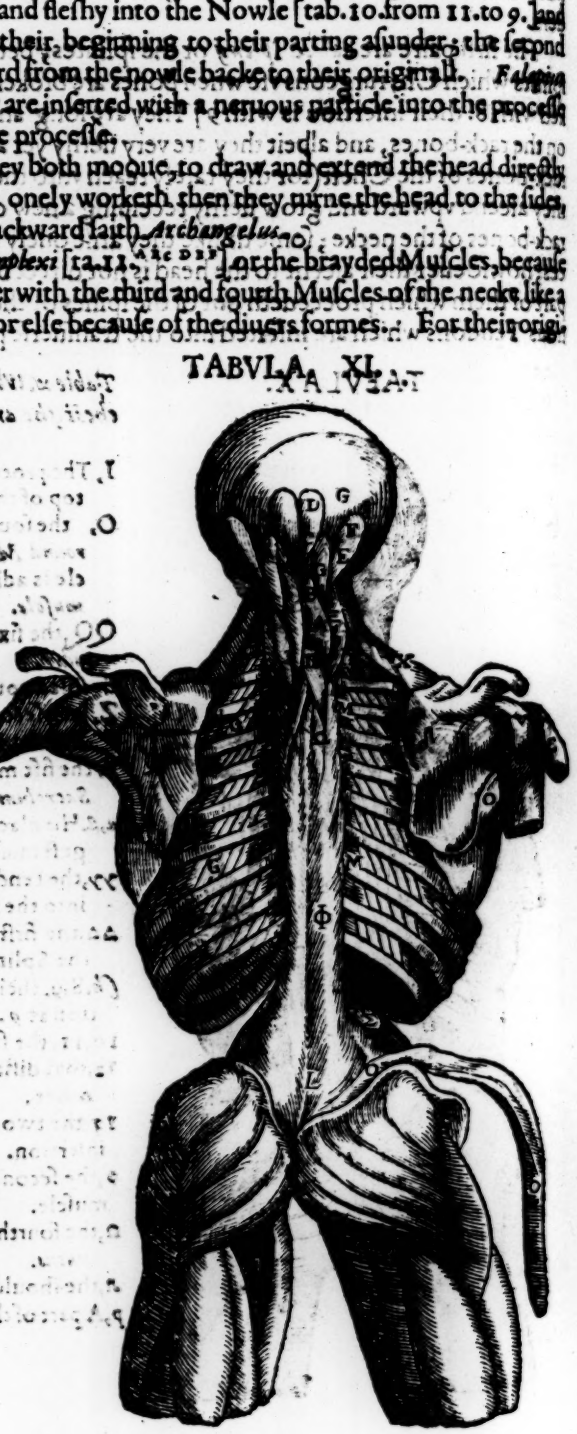

Table 11. *sheweth some Muscles of the Head, the Backe, the Chest, the Shoulder-blade and the Arme.*

A D, the second paire of the Muscles of the head or the two *Complexi*, the first part is at A D.
B C the second part, E F, the third part rising vp vnder G and inserted at F.
G, the fourth part of this muscle or the right muscle of the heade according to *Falopius*, which *Vesalius* made the fourth part of the second.
G G, (Betwixt the ribs) the externall *Intercostall* muscles.
L, the originall of the second muscle of the back.
M, His tendons at the rack-bone of the necke.
The vpper O the fourth muscle of the arme or the *greater round* muscle.
O O, the lower, the sixt muscle of the Chest or the *Sacrolumbus* hanging from his originall.
Q the sixt muscle of the arme or the vpper *Bladerider* inuerted.
V, the third ligament of the ioynt of the arme.
X, the fourth muscle of the shoulder-blade or the *heauer*.
Z, the second muscle of the Chest or the greater *Saw-muscle*.
Æ, the third muscle of the neck called *trãsuersalis*.
Π, the fourth muscle of the necke called *Spinatus*.
Σ, the first muscle of the back or the *Square muscle*
Φ, The second muscle of the backe or the *Longest* whose originall is at L and his tendons at the *vertebræ* at M M.
Ω the fourth muscle of the backe called *Spinatus*.
ſ, the backe of the shoulder-blade flayed.

nals

nals are of diuers faſhions, and they are diuerſly alſo inſerted into the Nowle or *occiput*. They haue many tendinous parts, and many alſo fleſhy, ſo that each of them ſeemes to be compounded as it were of three ſeuerall Muſcles, or rather hath three Originals. The firſt ariſeth farre off with a ſharpe originall euen out of the Tranſuerſe proceſſe of the fourth and fift rack-bones of the Cheſt, this immediately after his ſpringing appeareth fleſhy [at A] and of the faſhion of a Mouſe, when it atteyneth vnto the beginning of the Necke [at B] it ceaſeth to be fleſhy and endeth as it were in a round Tendon, and hauing ouercome the roote of the necke at [C] it groweth fleſhy againe (as the Muſcle of the bone *Hyois* called *Digaſtricus* or double-bellied) and ſo is inſerted in the middle of the Nowle-bone. [at D]

The ſecond originall or beginning of this Muſcle is ſhorter, growing round and neruous out of the ſpine of the ſeuenth racke bone of the necke. [at C] *Platerus* addeth ſom- The ſecond.
times of the firſt, and ſometimes of the ſecond, as it aſcendeth it becommeth fleſhie and is mingled with the former before his inſertion is implanted into the nowle. The third [Ta. 11 from ª to ʳ] is ſituated in the ſide and ſpringeth partly fleſhy, partly neruous from The third.
the tranſuerſe or ouerthwart proceſſes of the ſecond and firſt racke-bones of the Cheſt. *Platerus* addeth from the fiue lower of the necke. From thence it proceedeth obliquely outward and becommeth fleſhy and broad and is inſerted into the Nowle at the root of the Mammillary proceſſe, but it is not of the ſame forme in Dogs and Apes. Theſe muſcles if they worke together, they extend the head directly drawing it backward, if eyther of them mooue alone the head is drawne round to one ſide. *Archangelus* addeth a little alſo backward by the right and forward by the left.

The third paire (which *Veſalius* reckoneth for the fourth part of the ſecond Muſcle bee- The 3 paire
ing deceyued ſaith *Falopius* by certaine fibres of one of the muſcles of the backe vvhich grow to the beginning of it) [Tab. 11, ᵍᵍ] is not very great or thicke and is ſituated vnder the ſecond paire. They ariſe Neruous from the tranſuerſe proceſſes of the ſix firſt rack-bones of the necke; ſometimes alſo but rarely from the fiue vppermoſt of the cheſt; then it becommeth fleſhy and ſtretcheth obliquely vpward and inward, their Fibres teaching to the ſpines of the bones, and at their inſertion which is to the backewarde roote of the Mammillary proceſſe they end Neruous, receyuing an additament or encreaſe by two ſmall portions ariſing from the tranſuerſe proceſſe of the firſt rack-bone of the Necke. Their vſe is when they moue together to lead the head lightly backward; if either of them worke alone it draweth it backward to one ſide.

The fourth paire which are called *Recti maiores* the greater right Muſcles [Tab. 12, ᴬ ᴮ] The 4. paire
are yet ſmall, fleſhy and ſlender, ariſing from the top or height of the ſpine of the ſecond bone of the necke at [E] where they touch one another, but preſently part againe & aſcend both vpward and end round in the middle of the Nowle or *Occipitium*.

The fift paire called *Recti Minores*, the leſſer right muſcles [Tab. 12, ᴰᴰ] are ſituated vn- The 5. payre
der the former and are like them in ſubſtance, forme and progreſſe. They ariſe cloſe together from the back part of the firſt *Vertebra* where the bone ſhould haue ended in a ſpine but that ſpine is wanting, becauſe it would haue offended thoſe muſcles: preſently after their originall they part and aſcend vpward, and on either ſide are implanted round into The vſe of the two laſt paire.
the middle of the Nowle. The two laſt paires haue one and the ſame vſe, which is if they mooue together directly to extend the head drawing it backewarde, but if one of them mooue alone, it mooueth it circularly to one ſide. Nowe the reaſon why there are ſo many muſcles appointed to draw the head backward, is becauſe the forpart of the head by reaſon of the face and the neather Iaw is very heauy and weighty, and therefore needed more helpe to retract it, whereas it noddeth forward very eaſily.

The ſixt paire, according to *Veſalius* the fift, are called *Oliqui ſuperiores* the Vpper ob- The 6 paire.
lique muſcles, [Tab. 12, ᴴ ᴵ] they are ſeated vnder the right, and are like them in forme & ſubſtance: ſmall they are and ariſe out of the middle of the Nowle at the vtter ſide of the fourth paire, thence they deſcend downward, and are ouerthwartly inſerted into the top [at D.] of the tranſuerſe proceſſes of the firſt rackbone of the Necke, the right muſcle into the right proceſſe, and the left into the left. Their vſe is, if they both mooue to nodde gently and directly backward, if one alone then the head enclineth backward to that ſide the muſcle is on which mooueth.

The ſeauenth paire, according to *Veſalius* the ſixt, according to *Columbus* the fifte, are The 7. paire
called *Obliqui inferiores*, the lower oblique muſcles. [Tab. 12, ᴷ ᴸ] They ariſe from the ſpine

δ. His end.
Ω, The fourth muſcle of the backe called *Semiſpinatus.*
ε His vpper end vnder the fourth Muſcle of the necke.

of the ſecond rack-bone of the necke [from ᵃ to ᵇ] and paſsing obliquely vpward are implanted into the tranſuerſe proceſſes of the firſt *Vertebra.* Theſe, as alſo the oblique ſuperiors, are longiſh, round and fleſhy (farre larger in Dogs and Apes then in men) and do make a triangle of equall ſides.

The vſe of this ſeuenth paire is ſemicircularly to mooue the head (for it hath not perfect circular motion) with the ſecond *Vertebra* vpon the firſt when one mooueth alone. If they both mooue, either they keepe the head ſteddy as *Fallopius* in his obſeruations conceiueth, or elſe do draw it backward a very little, euen ſo much as may rather giue reſt to the ſecond racke-bone then motion; for the motion and reſt of the head followeth the motion or reſt of that ſecond *vertebra* or rack-bone.

The 8. paire. The eight paire which is the ſeuenth according to *Veſalius* are called *Maſtoidei* [Tab. 6 fig. 2 ᵃ the latter, ta. 7. fig. 2 ᵃ] They are ſeated forward toward the face next vnder a membranous and broad muſcle in the necke; [Tab. 6. fig. 1 r] ſtrong they are, long and round, and do appeare in leane carkaſſes vnder the skin before it bee diſſected, yea in liuing bodies, and theſe are they which the Ancients ſo diligently obſerued in their Coynes. They

Situation. ariſe from the middeſt of the top of the breſt-bone [at ρ] and from a part of the Clauicle where it approacheth neere the breſt-bone [at σ] to be articulated with it: at which their

Originall. originall they are Neruous and broad, but more neruous where they ariſe from the breſt bone, and from thence aſcend obliquely vpward and become fleſhy and thicke, and are obliquely inſerted with a fleſhy and thicke end into the Mamillary proceſſe (which they

Inſertion compaſſe with their largeneſſe) and into the backpart of the Nowle. [Tab. 6. fig. 2 the vpper τ] And this muſcle by reaſon of his double originall betweene which there is a kinde of hollownes [between ρ & σ. f. 2] becauſe it ſeemeth as if it might be diuided into two, ſom do diuide it into many. Their vſe is if they moue together to bend the head forwarde into

Vſe. the boſome as when we nodde, either carrying the necke ſtiffe or inclining it: if one of them onely worke then the head is mooued forward to the left ſide if it be the right Muſcle, and to the right ſide if it be the left, which motion we may plainly perceiue in guiding a horſes necke with the reines. This paire with the ſecond paire of the bone *Hyois* [Tab. 6. fig. 2 γ γ] make a croſſe in the Necke.

The

The ninth paire [ta.q.13. at the side of ᴬ ᵇ] is added by *Falopius*, described in some sort by *Galen*, and is situated vnder the gullet in the forepart of the necke: it is a diuerse muscle from the first paire of the necke [ta.13.ᴬ ᵇ] to which it adioyneth. It ariseth neruous from the Ligaments of the racke-bones of the necke, which Ligaments or Chordes doe arise from all the transuerse processes of the racke-bones of the necke, especally from the 7.6.5.4. and third.

After his originall this Muscle groweth somewhat fleshy, and ascending vpward is inserted with a fleshy end into the Basis of the head betwixt the two processes where the head is articulated with the first *vertebra*. His vse is when we nodde to bend the head somewhat forward. And thus much of the Muscles of the Head.

CHAP. XXII. *Of the Muscles of the Necke.*

THE Muscles which moue the Necke primarily, and secundarily or by accident the Head, are on either side three, or foure if you adde the *Scaleni*, which we account rather among the muscles of the Chest: these are situated vnder the Muscles of the Head, some of them before at the sides of the necke, some of them behinde.

These motions of the Necke are to bend forward to extend backeward to incline to the sides and to turne round as it were: but there are more Muscles to draw it backward then forward, because the labour is greater by reason of the waight of the Necke and the Head. The motions of the necke.

The first paire are the two Long Muscles [ta.13.ᴬ ᵇ] which are seated in the forepart of the Neck vnder the Gullet, wherefore they are also called the *vnder Gullet-lurkers*. These

Tab.13. sheweth the cauities of the middle & the lower Bellies, all the Bowels being taken out where the Bones and Muscles do remaine, excepting the Breast bone.

TABVLA. XIII.

A B, The first muscle bending the necke called *Longus*.
C C, The second bender of the necke called *Scalenus*.
DDDD, the outward *intercostall* muscles.
EEEE, The inner *intercostall* muscles.
FFF, The second muscle of the chest called *Serratus maior*.
G, the first muscle of the shoulder-blade called *Serratus minor* separated from his originall.
H, the first muscle of the arme called *Pectoralis* separated from his originall.
I, The 2. muscle of the arme called *Deltoides*.
K, the bone of the arme without flesh.
L, the first muscle of the cubite called *Biceps*.
M, the 2. muscle of the cubite called *Brachiæus*
N, the gristle or collick bone bent backward
O, the first muscle of the chest cald *Subclauius*
P, the vpper processe of the shoulder-blade.
Q, the first muscle of the head called *obliquus inferior*.
R, the 2. muscle of the head called *Complexus*.
S, the fourth muscle of the shoulder blade cal *Rhomboides*.
T V, The two bellies of the fourth muscle of the bone *Hyoides*.
X X, The fist muscle of the back whose originall is at *aa*.
Y Y, *cc*, The fixt muscle of the high called *Psoas*, whose originall is at *bb*, & tendon at *dd*.
Z Z, The first muscle of the thigh.
d, The hip bone. *eee*, The holes of the hip bone out of which the nerues do issue.
f, A portion of the fist muscle of the thigh ariuing from the shars-bone.
g, The shars bone bared. (*circumacter*.
h, The ninth muscle of the thigh or the first

ariſe with a fleſhy thin and ſharpe beginning from the body of the fifth racke bone of the cheſt where the rib is articulated to it, and aſcending broader doe grow to the fiue vpper *vertebra* of the cheſt and all of the necke. They alſo as they aſcend by degrees do approch or incline one to the other, yet ſo as they leaue the middle part where the gullet deſcendeth vncouered, but at their determination they ioyne in a neruous and ſharpe Tendon, and are implanted into the bunching proceſſe of the firſt racke bone: ſometimes but rarely they are implanted & that obſcurely into the nowle, euen at the great perforation thereof; ſo that it may ſeeme the nowle is turned by them. Their vſe is by their propper motion when they work together to bend the necke directly foreward and withall to incline the head, but if one of them moue alone, then is the necke inclined forward into that ſide which is contracted, or on which the muſcle moueth.

The 2. paire

The ſecond paire make thoſe which are called *Scaleni* and are accounted as the 8. muſcle of the Cheſt. [tab. 13. cc. tab. 12. A.] Their ſituation is on the ſides of the necke rather before then behinde. They are eſteemed to ariſe fleſhy and large from the firſt rib, and to be inſerted into all the tranſuerſe proceſſes of the racke-bones of the necke, excepting ſometimes the firſt and the ſecond; from which we thinke with *Falopius* they haue their originall. Their vſe is alſo thought to be, to bend the necke foreward as doth the firſt paire: this one thing is peculier to them ſaith *Veſalius*, and *Platerus* conſenteth, that they haue a through-paſſage by which the veines and arteries do run into the arme.

The 3 paire.

The third paire (which *Veſalius* maketh the third paire of the back, but *Platerus* the third paire of the necke) are called *Tranſuerſales*, or the two ouerthwart muſcles. [Tab. 11. E.] Their ſeate is in the backe, and they ariſe from the rootes of the tranſuerſe proceſſes of the ſixe vppermoſt rackebones of the Cheſt, from whence by degrees they become ſtronger and thicker, and are inſerted into the outſide of the tranſuerſe proceſſes of all the bones of the necke, but more rarely into the firſt. Sometimes they haue two other originals, one from the ſecond paire of muſcles of the backe, the other from the fift paire of the cheſt, which together make vp theſe muſcles. Their vſe is, if they worke together to extend directly backeward, if one of them alone the motion is not direct but oblique. Alſo betweene theſe do paſſe thoſe nerues of the marrow of the backe which come out of the rackebones of the necke.

The 4. paire.

The fourth paire called *Spinati* becauſe they are ſeated among the ſpines of the *vertebra* [tab. 12. H.] do occupy or take vp the whole necke. They ariſe from the rootes of the ſpines of the ſeuen vppermoſt bones of the cheſt; and after they haue attained the lowermoſt *vertebra* of the necke, they gather a broader originall therefrom, and yet with the fibres which they receiued frō the *vertebra* of the cheſt they indeuour an obſcure inſertiō in to the ſpine of the lowermoſt *vertebra*: but they grow more ſtrongly to the reſt of the ſpines of the necke bones, and draw new beginnings from the rootes of their tranuerſe proceſſes euen to the ſecond *vertebra*, and inſert the fibres they receiue from them into the ſpines of the rackebone next aboue, till they haue implanted themſelues ouer all the ſpine of that ſecond racke bone of the necke, where the right is ioyned with the left: and indeede they ioyne all along their progreſſe vp the necke ſauing where the ſpines of the bones peepe vp betweene them and ſeuer them a little aſunder. Their fibres at their originall are outward, but as they aſcend they incline inward.

Their quaint paſſages.

Their vſe is if they worke together, to extend the necke, drawing it directly backward, but if one of them moue alone then is their motion not direct but oblique to the ſide contracted, or on which the muſcle moueth. And ſo much of the muſcles of the necke.

CHAP. XXIII. *Of the muſcles of the Shoulder-blade called Omoplata or Scapula.*

Why the ſhoulder-blade doth not moue round

THe Shoulder-blade hath foure right motions, forward, backeward, vpward downeward: for which it is prouided of foure muſcles, *Galen* ſaith ſeuen, & *Syluius* reckons fiue, but al the reſt agree in foure, for it is not moued round, for then it could not ſo firmele hold the ſhoulder bone, and beſides the clauicles being faſtened vnto it do keepe it from turning.

The 1. muſcle

The firſt muſcle of the Shoulder-blade is called *Serratus minor* the leſſer Saw muſcle, [tab. 14. S.] it lieth vnder the pectoral muſcle. His originall is broad, and as it were, fingerfanged from the 4 vpper ribs (excepting the firſt, and very rarely from the ſixth) a little before they end into their griſtles, that his originall might be the firmer: & aſcending obliquely vpward, it groweth fleſhy and neare the ioynt narrow, and hauing faſhioned the figure

of

Table 14. sheweth the body, such as it appeareth after the Bowelles of the Lower and Middle Bellies are taken away. The right Arme with his Muscles remayneth in his naturall situation, except the Pectorall and the lesser Saw-muscles, which were necessarily to bee separated and taken away with the Breast-bone. The left Arme is removed from the side, that the blade of the shoulder and the Clauicle, and those things which lye vnder them might better appeare.

TABVLA. XIIII.

AA, the first muscle of the cubit called *Biceps*.
B, the second muscle of the cubit in the left arme called *Brachiæus*.
DE, the first paire of muscles of the necke vnder the gullet.
F, the 2. of the neck arising from the first rib.
GGG, the outward *intercostall* muscles.
HHH, Letters set vppon the ribbes which should haue been placed vpon the inner *intercostall* muscles.
I, the left clauicle or collet-bone remoued from his place and bared.
K, the right clauicle or collet-bone in his owne place.
L, the first muscle of the arme called *Rectoralis*, remoued from his originall.
a b y. The circumscription of this muscle.
b, His tendon and insertion.
M, The second muscle of the arme called *Deltois*.
H, his originall and insertion.
N, the same muscle separated and reclined from his originall.
O, The fourth muscle of the Arme called *Rotundus maior*.
Q, the 3. muscle of the cubite or the first extender.
R, The seauenth of the arme called *Subscapularis*.
r, his insertion into the arme.
S, The tendon of the third muscle of the arme called *Latissimus*.
S, The first muscle of the shoulder-blade called *Serratus minor*, eleuated from his implantation.
TT, the 7. muscle of the thigh called *Iliacus internus*.
Y, the first muscle of the chest called *subclauius*.
ZZ, the 2. muscle of the Chest called *Serratus maior*. ΣΣ, the first muscle of the back called *quadratus*. Ω, the round *Pronator* or inclineer of the *Radius* or wand. αα, the first bender of the Leg. ββ, the 2. bender of the Leg. σσ, the first paire of benders of the thigh called *Lumbales*, whose head is marked with *a* and his tendon with *b*, νν, the third paire of benders of the thigh. ρρ, Paires of nerues which goe vnto the thigh, ω, the Holy-bone.

of a Triangle is inserted with a Tendon partly fleshy partly neruous, into the shoulder-blade neare the inner processe called *Acromion*. His vse is to bend the shoulder-blade forward to the Chest: for if his vpper fibres be contracted it moueth it to the brest higher, if his lower, lower: if his middle fibres, then directly or in a straight line.

The second is called *Cucullaris* or the Monkes-hood [tab. 15. I] because with his other companion it couereth the backe as that doeth, or as a countrey wiues broade white kerchiefe; *Galen* calleth it *Trapezius* or the Table-muscle. His originall is fleshy and thinne, and transuerse or rather oblique from the Nowle [from ο to π] but membranous & broad from the toppe of the spines of the necke euen vnto the height of the Chest: [from ο to ρ] from thence it is straightned as it passeth toward the shoulder-blade, and is implanted fleshy and sinnewy into the spine of the blade, the top of the shoulder-bone and the middle almost of his Basis, and into the broader part of the *Clauicle*. [π υ] Where it looketh toward the necke of the blade, you shall meete with a membranous and neruous semicircle [ο] ordained haply least it should too straightly presse the muscle which sitteth vppon the gibbous part of the shoulder-blade [κ]. The 2. muscle.

TABVLA XV.

Sheweth the muſcles on the backeſide of the body.

A, A part of the 2 muſcle of the cubit called *Brach.*
B, The vpper and vtter part of the ſecond muſcle of the cubit called *Brachiæus.*
C, The third muſcle of the cubite.
D, The fourth muſcle of the cubite.
K, The inſertion of the ſeuenth muſcle of the head called *Maſtoides* into the mammillary proceſſe.
M, M, the ſecond muſcle of the arme called *Deltoes*
N, N, The third muſcle of the arme called *Latiſſimus* circumſcribed with χχμ; a part of whoſe tendon at the inſertion in the former table is noted with ξ.
τ, The vpper part of the Cowle muſcle.
O, O, The fourth muſcle of the arme called *Rotundus maior.*
P, P, The fifth of the arme called *ſuper-ſcapularis inferior.*
Π, The firſt part of the *ſupinator* of the *Radius* or wand.
ϟ, A portion of the oblique deſcendent muſcle of the *Abdomen.*
I, the ſecond muſcle of the ſhoulder blade called *Cucullaris.*
α, the originall of this muſcle from the nowle.
ρ, From the ſpines of eight rackbones of the cheſt
From σ to τ, from the ſpines of the necke.
τ υ, His inſertion into the ſpine of the blade, into the arme and clauicle.
φ, His membranous ſemicircle.
β, the fift muſcle of the leg called *Semimembranoſus.*
γ, the fourth muſcle of the leg called *biceps.*
δ, the 3 muſcle of the leg called *Semitendinoſus.*
ζ, the fleſhy part of the firſt muſcle of the leg or of the firſt extender.
ϖ, the ſeuenth muſcle of the leg, or the ſecond extender couered ouer with the membranous tedon of the firſt.
μμ, the firſt muſcle of the thigh, or the firſt author of the buttockes.
i k l m n, His originall at i k l, his inſertion at m n.
ν, the ſecond muſcle of the thigh hidde almoſt by the former.
ρ, A part of the 5 muſcle of the thigh called *tricep.*

It is circumſcribed or limited with fiue lines; the firſt is ouerthwart at the nowle, [from α to τ,] the ſecond runneth ſtraight along the ſpines, [from σ to ρ,] two are oblique, one of them from the eare to the canell bone, the other from the ende of the ſtraight line which I ſayd did runne along the ſpines. [tab. 15. from τ to ρ.] The fifth and laſt is tranuerſe in the middle of the muſcle, where it is inſerted into the ſpine of the blade, the top of the ſhoulder and the broade part of the cannell bone or clauicle. Wherefore this ſecond muſcle as well by reaſon of his diuers originall as alſo his ſeuerall kindes of fibres, mooueth the ſhoulder blade diuerſly. For when the fibres which run along obliquely downeward from the nowle and the ſpine of the neck are retracted, that is, when the vpper part of the muſcle is retracted [at τ,] then is the ſhoulder blade lift obliquely vpward, but when the fibres which proceede from the ſpines of the cheſt obliquely vpward are gathered into themſelues, that is, when the lowet part is contracted together [tab. 15. ρ.] then the blade is drawne downward, but if the middle of the tranuerſe fibres be contracted [at υ.] then the blade is directly led to the backe.

The 5 lines of this muſcle

The third muſcle is called *Rhomboides*, that is, the ſquare muſcle, [tab. 16. ν.] It is ſituated vnder the former, thin it is, broad & four cornered, and groweth fleſhy from the ſpine of the three lower rackebones of the necke, and the three vpper of the cheſt, and his fibres run oblique from the backe to the bottome or foundation of the blade, into which baſis of the blade it is alſo beingbroade, fleſhily inſerted after the length of it, and draweth it vpward ſomewhat and backeward, and coucheth it to the backe.

The third muſcle.

The

TABVLA XVII. *Sheweth some muscles of the Head and the Chest, the Cowle-Muscle being taken away, as also of the Blade and of the Arme.*

A. The prominent part of the fourth muscle of the Chest, called *serratus posticus superior.*
Δ, the first muscle of the head called *splenius.*
E, E. The insertion of the second muscle of the head called *Complexus.*
L. The coller bone bared.
M. The backpart of the second muscle of the arme called *Deltoides.*
H. His backward originall.
I. His implantation into the arme.
NN. the 4 muscle of the arm cald *Latissimus.*
Σ, μ. His originall from the spines of the rack bones, and from the holy bone.
τ, The connexion of this muscle with the hanchbone which is led in the inside from μ to π.
ρ, the place where it lieth vpon the lower angle of the Basis of the shoulder blade.
O, the 4. muscle of the arme called *Rotundus maior.*
*, Some muscles of the backe do here offer themselues.
P, the fift muscle of the arme called *Superscapularis Inferior.*
Q. The 6. muscle of the arme called *Super Scapularis Superior.*
S, The beginning of the third muscle of the arme called *Latissimus.*
V, the third muscle of the Blade cald *Rhomboides.*
ρ, X, His originall from the spines of the rack bones.
ψ, ω. His insertion into the Basis of the shoulder blade.
χ, The 4 muscle of the Blade called *Leuator.*
ϑ, A part of the oblique descendent muscle of the *Abdomen.*

The other Letters in the thigh haue the same reference which they had in the former Table.

The fourth Muscle is called *Leuator* or the Heauer [Tab. 26 at χ] and is situated aboue the clauicle. His originall is very diuerse (whereat it is that some haue made diuerse Muscles of it) from the transuerse processes of the necke bones of the necke, and commonlie from the 1, 3, 4, 5, but rarely from the second. But these diuers originals do sound grow into one, and passing downe do make a strong and fleshy muscle, which is inserted with a broad and fleshy sension (his fibres being all of them almost right, few oblique) to the vpper and inner angle of the shoulder-blade. His vse is to draw the blade vpward toward the fore-part and to the sides of the necke. The 4 muscle.

These are the Muscles by which the blade is moued originally, the arme by accident, as also the blade is moued by accident by the Muscles of the arme, for when they draw the arme, they draw the blade also by consecution which is annexed thereto.

CHAP. XXIIII. *Of the Muscles of the arme.*

THE Ancients called all that the Hand which is betwixt the toppe of the Shoulder and the Fingers. The first part therefore of the whole Hand is called in Latine *Humerus*, which we translate the Arme, and it reacheth from the top of the shoulder to the next ioynt or bending of the Cubit, which we call the Elbow. The *Grecians* call this part βραχίων, and the cauity which is vnder the ioynt at the shoulder is called *ala* the *Arme-pit.* The toppe iust against the pitte is properly called the *Shoulder.* This member that it may more easily be moued euery way is articulated with the shoulder blade by *Enarthrosis* (which kind of articulation wee shall make plaine in the Booke of Bones) and mooued by Muscles. The particular partes of the arme.

The

The voluntary motions of the Arme are fiue: forward to the Breaſt, backeward toward the backe, vpward toward the necke and the head, downeward to the ſides of the cheſt, and finally, it is moued in compaſſe or circumuerted. For all theſe motions there are ſeauen Muſcles: ſome of which as the firſt and the third are faſtned to the Cheſt, the reſt grow vnto the ſhoulder-blade.

All theſe we will deſcribe according to the order of diſſection: yet firſt we giue you to vnderſtand that *Galen* in his Booke *de diſſectione Muſculorum* and the 18. Chapter, reckoneth eleuen, three aſcending from the Breaſt vnto the Arme, two from the regions of the handes, and fiue from the ſhoulder-blade, the eleauenth ſeaſeth vppon the *Eopmis*. *Veſalius*, *Columbus*, *Arthangelus* and *Falopius* in his inſtitutions reckon ſeauen: the ſame *Falopius* in his obſeruations and *Laurentius* account eight. But wee hold vs to ſeauen according to the Authours aboue named and *Bauhine* with them.

The firſt. The firſt is called *Pectoralis* the Pectorall Muſcle [ta. 17.ᵃ] ſo named from his ſituation, becauſe it occupieth the forepart of the Cheſt. It is a large muſcle and fleſhy, and becauſe of his originall it conſiſteth of vnequall ſides: whence it was that it is called by *Laurentius Pentagonius* or *quinquelaterius* as hauing fiue ſides. It groweth almoſt to the whole Breaſt-bone and the griſtle thereto annexed, to the middle of the clauicle where it is neareſt to the Breaſt-bone and to the griſtles of the 6. 7. and 8. ribs: ſo as it may ſeeme to him that takes but an ouert view thereof, to be compounded of many muſcles. [ta. 17.ᵇ doe circumſcribe it, and ta. 18. fig. 1.] Yea *Galen* himſelfe in the 18. chap. of his Booke *de diſſectione Muſculorum*, and the 13. of the 13. *de vſu partium*, thinketh it may be deuided into 3. or foure, but *Columbus* reprehendeth him for it. Notwithſtanding for *Galen* wee may ſay; that from the clauicles it ariſeth with a fleſhy originall, and from the middle of the Breaſt-bone and the griſtles of the ribs which are membranous and neruous. Afterward by degrees it becommeth thicker and more fleſhy, and is againe by degrees ſtraightned & gathered narrow, reſeruing in the vpper part by reaſon of the ſhort courſe of his fibres a fleſhy body, but below long before his inſertion it appeareth liuid and neruous, and the depth and bottome thereof is much ſlenderer then the vpper part.

His original diuers.

[*Table* 17. *is the ſame with Table* 14. *Folio* 773.]

Implantation At length it is implanted with a ſhort but broad ſinnewy and ſtrong tendon [tab. 17. and ta. 18. fig. 1. and 2. ᵈ] to the bone of the arme longdwiſe a little below the inner head thereof, betwixt the muſcle called *Deltoides* and that which is called *Biceps*. [ta. 17. and ta. 18. fig. 1. ᵉ ᶠ] But at his implantation hee bendeth forwards as if his tendon were reduplicated. And truely in ſome men a portion of it is found to grow into a kind of point, imitating a peculiar muſcle, whereas indeed it is a part of this muſcle wee now entreat of. Albeit *Columbus* thinketh that *Galen* in the 18. chapter of his Booke *de diſſect. muſc.* deſcribeth this production for a particular muſcle.

His vſe. This *Pectorall* muſcle by reaſon of his diuers originall hath alſo diuers fibres: ſome runne obliquely downward from aboue, others obliquely vpward from below: inſomuch that a little before the muſcle produceth his tendon theſe fibres ſeeme to interſect one another in a decuſſation, and yet all of them concur together into one angle to forme the tendon. This variety of fibres maketh the different motions which this muſcle performeth.

This office of this muſcle is when it contracteth equally all his fibres, eſpecially the middlemoſt in euery part of his body, to moue the arme equally and directly forward, inclining on neither hand, and to leade it to the breaſt. But if all the fibres be not equally contracted, then is it ledde indeed to the Breaſt but obliquely, more vpward or more downeward as the different fibres are contracted.

The ſecond The ſecond Muſcle of the arme is called *Deltoides*, from the forme of the Letter Δ: [ta. 17. a. 18. fig. 1. 2. 4. ᵍ] ſome call it *Epomis*, becauſe it lyeth vnder the leſſer head of the arme which is properly called *Epomis* by *Hippocrates*, *Galen*, *Ruffus* and *Oribaſius*, as *Falopius* in his obſeruations hath very well obſerued, thereby cleating no ſmall Controuerſie in our *Art* about the acception of the word *Epomis* in *Hippocrates* and the Ancients. Some call it *Humeralis* or the Arme muſcle by a kinde of excellencie.

hie name.

What *Epomis* is.

It is fleſhy and triangular, or *tetragonall* ſayeth *Archangelus*, ariſing from the middeſt of the clauicle where it regardeth the ſhoulder-blade, from the top of the arme where it is ioyned to the clauicle, and from the whole ſpine of the ſhoulder-blade [ta. 16. & ta. 18.

fig.

fig.1,ζ] But you muſt not conceyue that it taketh his Originall from the ground or ſoale of theſe bones, but from a certaine prominence or thicke line bearing out from them.

Note moreouer, that in the originall this Muſcle is broade (as being compounded of diuers yet continued beginnings like ſo many ſeuerall muſcles) & Neruous: (tendinous ſayth *Columbus*) but preſently becommeth fleſhy and thicke, and ſo remaineth till by degrees it be anguſtated or ſtraightned into the toppe or corner of the triangle, and ſo at length endeth into a ſtrong Tendon which is partly fleſhy, to wit, on the outſide, and partly Neruous, to wit, on the inſide, appearing in our diſſections to lye not perfectlie ouerthwart yet more then oblique. It embraceth or compaſſeth the middle thickeneſſe of the arme, and is inſerted in the middeſt thereof vnder the necke of it. [Table 18. fig. 2,ϑ] Originall. Inſertion.

This Muſcle alſo hath Fibres ſomewhat diuers, thoſe of the fore part run obliquelie downward and backward, thoſe of the backe part runne obliquely forward. And ſome of theſe do appeare to be a little implicated or entangled one within another: but the middle Fibres tend directly downward. Wherefore when the *anterior* Fibres are contracted the arme is lifted vpward and forward towards the face, when the backeward Fibres are contracted, then is the arme lifted backeward toward the Nowle, but when the middle Fibres are equally contracted then is the arme eleuated directly vpward. Vſe.

The third muſcle of the arme is called *Latiſſimus*, that is, the broad muſcle, and *Aniſcalptor* the *Pruritan* muſcle, [Tab.15 & 16 ν. Ta.25 ſheweth it ſeparated] becauſe it reacheth neere to the buttockes, for together with his fellowe it couereth almoſt the vvhole backe, and therefore may well bee called (ſaith *Bauhine*) *Dorſalis Maximus*, the Greateſt Muſcle of the backe. It ariſeth with a membranous and broad beginning from the tops of the ſpines of the Rack-bones which are betwixt the ſixt *vertebra* of the Cheſt, and the middle of the Holy-bone, [Tab.16 S,μ] as alſo from the vpper part of the haunch-bone: thence aſcending, when it attaineth to that part of the back where the ribs ſwell out backward it becommeth more fleſhy, and climbing ouer the lower angle of the baſis of the ſhoulder-blade it groweth narrower, and is inſerted belowe the vpper head of the arme lengthwiſe on the inſide betwixt the Pectorall and the Round Muſcles; his tendon being ſtrong and ſhort, yet broad and as it were reflected. For betwixt the tendons of thoſe two forenamed muſcles there is a diſtance left for this inſertion, in which place alſo is the cauity of the arme-pit made by this Muſcle and the Pectorall. The 3. muſcle Originall. Inſertion.

The figure of it is Triangular, for it hath three vnequall Angles, two long and one ſhort. The ſharpeſt is that which groweth from the *Holy-bone*: the nexte is at the Cheſt where the Muſcle yſſueth from the Ridge of the Rackes. The third is at the arme and endeth into the tendon. Moreouer, this Muſcle when it attaineth to the lower angle of the ſhoulder-blade, receyueth ſometimes therefrom many fleſhy Fibres, as *Galen* well obſerued in his Anatomicall Adminiſtrations and in the 12 chap. of his 13 Booke *de vſu part.* which Fibres do repreſent a newe but ſmall Originall. *Veſalius* denies this and holdeth it not to touch the ſhoulder-blade, but by the interuening of Muſcles which ariſe therefrom, and that it groweth not at all to the bone; but as he reproueth *Galen*, ſo *Falopius* in his Inſtitutions reprooueth him, affirming that in all the bodies that euer hee made diſſection of he found this Muſcle faſtened to the blade. *Galen* redeemed from *Veſalius*.

Bauhine rendreth a reaſon. It groweth (ſaith he) with certain Fibres to the baſis of the ſhoulder-blade, leaſt when the blade is mooued it ſhould ride ouer the muſcle, for theſe Fibres as it were Ligaments do hold the Muſcle and the blade together. *Galen* alſo in the fift chap. of his 13 booke *de vſu part.* faith, that by the benefit of this adheſion or cleauing the blade alſo is mooued downward by this thirde muſcle. Notwithſtanding, *Falopius* dares not for certaine affirme that it doth mooue the blade, but that it conferreth ſomething to his motion he is very confident againſt *Veſalius*.

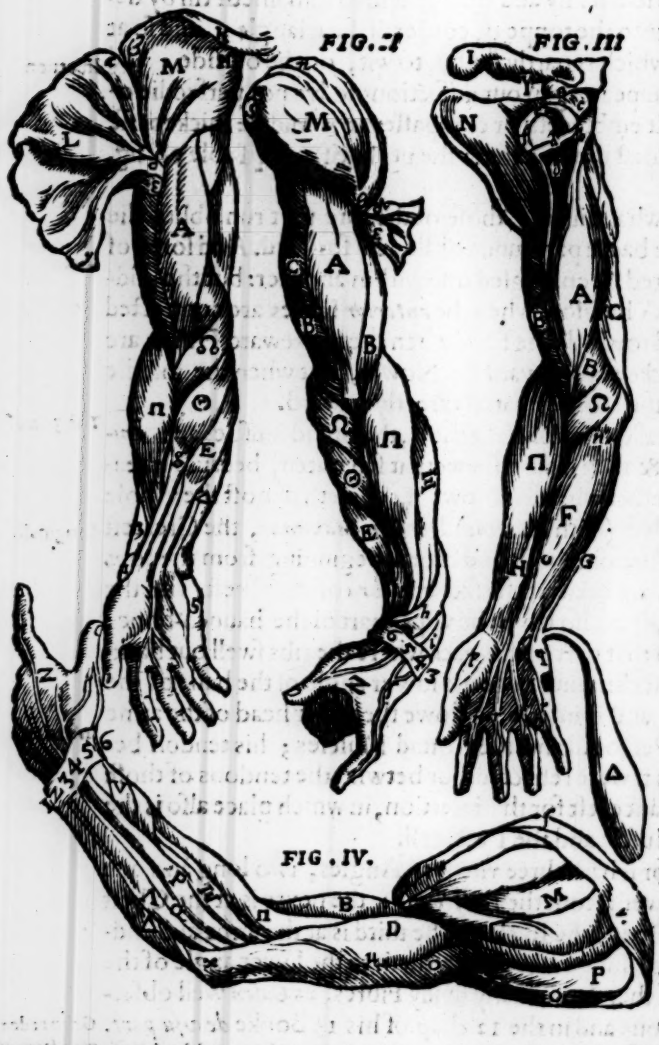
The Fibres alſo of this Muſcle do differ according to the inequality of the ribbes; for ſome are long and leſſe oblique, others are ſhort and more tranſuerſe. Wherefore, as theſe fibres are contracted into themſelues, the arme is more or leſſe retracted downeward and depreſſed toward the backe, ſometimes higher, ſometimes lower.

The fourth Muſcle is called *Rotundus maior*, almoſt by common conſent of all Anatomiſts, *The greater round Muſcle*. [Tab.10,11,14,15,16,25 and Tab.12.fig.4 O] *Platerius* alſo calleth it the *Longer tranſuerſe Muſcle* becauſe it is ſeated obliquely on the backe ſide vnder the arme-hole. It is fleſhy, thicke and rounder then all the reſt. His Originall The 4 muſcle His name.

is

Tab. 18. *Sheweth in foure figures the muſcles of the arme, the cubit the wriſt, the wand and the fingers of the hand.*

TABVLA XVIII.



A, 1,2,3. The firſt muſcle of the cubit called *Biceps*.
B B, 2. 3,4. The ſecond muſcle of the cubite called *Brachiæus*.
C. 2,3,4. The third muſcle of the cubit called *Longus* or a part therof
D. 4, The fourth muſcle of the cubit or the ſhort muſcle.
E, 1,2. The muſcle in the palme of the hand.
F, 3. The firſt muſcle of thoſe which bend the foure fingers.
G, 3, A portiō of the ſecond of thoſe which bend the foure fingers.
H, 3, The firſt of thoſe which bend the thumbe.
I, 3, The clauicle or coller-bone remoued from his ſeate and bored
K, 1, The coller bone in his owne place.
L. 1, The pectorall muſcle or the firſt of the Arme.
α β γ. His circumſcription and originall.
δ 1, 1. and 2. His inſertion.
μ, 1, 2, & 4, The muſcle called *Deltois* or the ſecond muſcle of the arme.
ζ ν, His broade originall.
θ, His inſertion.
ν ζ, The muſcle called *Deltois* ſeparated and the inner part of it.
O, 4, The greater round muſcle, or the fourth muſcle of the arme.
P, 4, The lower *Superſcapularis*, or blade rider, or the fourth muſcle of the arme.
p, 4, the lower. The firſt of thoſe muſcles which extend the 4. fingers.
Q, 4. The ſecond muſcle of the extenders of the foure fingers.
S, 1, 3. The fourth of the extenders of the foure fingers.
V, 4, The ſecond muſcle of thoſe which extend the thumbe. Y, 3, The ſubclauian muſcle or the firſt muſcle of cheſt. Z, 2, 4, The fourth muſcle of the extenders of the thumbe. a, b, 3. The higher proceſſe of the ſhoulder at a, the lower at b. c, 3, The brode ligament of the ioynt of the ſholder blade with the arme. d, 3, The lower round ligament. e, The vpper round ligament. f, 3, The coniunction of theſe two ligaments. g, 3, The bone of the arme ſleade. h, i, 1, 2, Portions of the muſcles of the fingers from the vtter ſeat of the cubite propogated vnto the Tendons of the hands. l, 2, Tendons in the hand reached vnto the outward ſeat of the fore finger of the Char. 1, 2, 3, 4, 5, 6, in the 2. and 4. figure: the tranuerſe ligament of the wriſt diuided into ſo many ſmall circles. n. The originall of the firſt muſcle bending the fingers vnder the muſcle noted with n. o, 3, Fleſhy portions of this muſcle perforating the foure Tendons at r, r, r, r, p, q, The tranſuerſe ligament of the wriſt diuided and led on both ſides. r, r, r, r, 3, Foure tendons carryed vnto the fingers. ſ, 3, The vpper munks hood or cowle muſcle. t, His lower ſeate. u, y, The coniunction of the third & fifth muſcle of the cubit which *Veſalius* doth diuide. x, 4, His inſertion and a portion of the Ell fleade Δ, 1, 3, 4, The firſt muſcle bending the wriſt. Θ, 1, The ſecond bending the wriſt. Λ, 4, The firſt muſcle extending the wriſt, Ξ, 2, 4, The 2, extending the wriſt. Π. 2, 3, 4, The firſt ſupinator of the wand which turnes the hand vpward. Ω, 1. 2, 3, The other pronator of the wand which turns the hand do wneward a. 3. The inſertion of the ſuperſcapularis, or blade rider.

is but ſmall-yet continuall and fleſhy which it taketh from the lower ribbe or ridge of the blade at that part which is neare to the baſis, thence paſſing along when it cometh to the middle of that ridge or rib it departeth from the Blade-bone, and ariſing a litle vpward is inſerted into the vpper and inner part of the Arme with a ſhort but broad, ſtrong, membranous & neruous Tendon, where alſo it finds the 1. muſcle couched & their Tendons a like. The vſe of this Muſcle (ſayeth *Bauhine*) is to retract the arme downeward, and ſo it is

contrary

contrary to the ſecond muſcle called *Deltoides*. *Galen* reckons it among the *Turners* of the arme, for (ſayth he) it turneth the arme outward: *Veſalius* reprehends him and ſayeth that it applyeth the arme directly to the backe. But *Archangelus* beſide that direct motion, aſcribeth vnto it an outward motion and a little inward. *Laurentius* would haue his motion to be onely oblique.

At the lower part of this Muſcle or at the lower rib or ridge of the blade we finde a diſtinct portion implanted with a neruous termination neare the inſertion of the 5. muſcle which *Falopius* maketh the eight muſcle of the arme, which (ſayth hee) is manifeſtly ſeparated from all the reſt, as I haue found in all my Diſſections, and I wonder much (ſayeth he) that our late Anatomiſts haue ouer-skipt this muſcle, which is of great moment as being together with the ſeauenth the authour of the ſame motion, eſpecially becauſe *Galen* obſerued it in Apes in the 18. chapter of his Booke *de diſſect. muſcul.* and in the firſt chapter of the 5. Booke of his Anatomicall Adminiſtrations. The eight muſcle after *Falopius*.

The fift Muſcle of the Arme is called *Superſcapularis inferior*, the lower Blade-rider, [tab. 15, 16. 25. tab. 18. fig. 4. P.] It couereth all the outward and gibbous part of the blade which is vnder his ſpine and beareth the forme thereof. It ariſeth fleſhy from the Baſis of the blade below the ſpine, becomming narrow as the blade-bone groweth narrow, & is inſerted obſcurely ſemicircular wiſe to the outſide of the Ligament of the arme which holdeth the ioynt. The 5. muſcle

The vſe of it is (ſayth *Bauhine*) to leade the arme in compaſſe outward, *Archangelus* addeth vpward alſo, *Laurentius* ſaith it retracteth it backward.

The ſixt Muſcle called *Superſcapularis ſuperior* or the vpper Blade-rider, is alſo called *Rotundus minor* the Leſſer round Muſcle. [table. 10. 11. 15. 16. 25. Q] It is ſeated aboue the the Arme-hole and filleth all the cauity which is betwixt the vpper ribbe or ridge of the blade and the ſpine of the ſame; from which it ariſeth fleſhy, long and hauing long fibres, for it proceedeth from that Baſis of the blade-bone to which it groweth very ſtrongly, and when it attayneth to the vpper part of the neck of the Blade, it runneth vnder a tranſuerſe Ligament which coupleth the arme to the inner proceſſe of the blade, and with a broade and ſtrong Tendon riding ouer the ioynt is obliquely inſerted to the Ligament thereof. The ſixt muſcle.

The vſe of this Muſcle ſaith *Bauhine* is the ſame with that which went before and which followeth after, *Archangelus* ſayth it leadeth the Arme vpward and backward, *Laurentius* backward onely. *Veſſalius* doeth not thinke that *Galen* makes any mention of this Muſcle, vnleſſe haply it bee reckoned among the Heauers of the Arme, for none of his deſcriptions agree thereto, although he make light mention of a muſcle riding ouer the vpper rib of the blade.

The ſeauenth muſcle called *Subſcapularis* the Blade-lurker, or *Immerſus* the drowned Muſcle, [tab. 17. R] is ſeated betwixt the Blade-bone and the ribs. Very fleſhy it is and continual with the former on the vpper ſide, occupying the inner hollow part of the Blade-bone, from whence it ariſeth. It is like the Blade triangular, ſtraightned by degrees at the inſide of the ioynt, and with a broad Tendon is Semicircularly inſerted into the inſide of the arme, (*Laurentius* ſayth into the necke and head of the arme) ſo that the Tendons of the 3. muſcles which leade the arme about do orbicularly incompaſſe the whole ligament of the ioynt. The 7. muſcle.

His vſe is to leade about the Arme inward, *Galen* in the 18. chapter of his Booke *de diſſect. muſcul.* ſayeth that it circumuerteth the head of the arme backeward: *Archangelus* that it moueth the arme vpward and inward, *Laurentius* that this together with the leſſer round muſcle and that which is called *Infra-ſpinatus* doe moue the arme ſemicircularly backward, for (ſayth he) a perfect circular motion the arme hath not from any peculiar muſcle, but by the ſucceſsiue working of them all, for that which is circular is compoſided of all the right and all the oblique.

That notable muſculous portion ariſing from the proceſſe of the Blade-bone which is like an Anchor, and inſerted into the arme; *Arantius* and *Placentinus* doe eſteeme to bee a muſcle of the arme; others account it for the firſt muſcle of the cubit. His vſe ſay they is to leade the arme to the proceſſe of the Blade-bone, and indeede the motions of the arme and cubit are neare of kinne, for when the cubit is bent in the Elbow, it is moſt what neceſſary that the arme alſo ſhould be lifted vp, as we may obſerue in our ſelues, and ſo much of the muſcles of the Arme. The muſculous portion.

CHAP.

CHAP. XXV. *Of the Muſcles of the Cubit.*

The bones of the Cubite.

THe Cubit which is the ſecond part of the Hande in the large acceptation, conſiſteth of two bones, the firſt is called *Cubitus* or *Vlna*, the Cubite or the Ell, and we retaine that name when we call the place where it is bent the *Elbow*. The ſecond bone is called *Radius* or the *Wand*. Theſe bones haue diuers motions, and therefore the Muſcles of the Ell and the Wand are diuers. The Cubit or Ell hath two motions, for it is bent and extended directly. *Galen* attributeth alſo to it an oblique motion, which *Columbus* ſaith is neuer to bee founde in a man the *Radius* or wand being mooued turnes the hand vpward and downward. Firſt we will ſpeake of the motions of the Cubite which are performed by the helpe of foure Muſcles, ſome ſay fiue, and theſe are called the muſcles of the Cubite, not becauſe they are ſeated in the Cubit, but becauſe they mooue it. For they ariſe from the arme and the blade, and take vp the roome along the arme; The two *Benders*, the inſide or fore-ſide, and the two or three extenders the outſide or the backeſide. But theſe Muſcles which are ſeated in the cubit it ſelfe do ſerue to mooue eyther the Wand, or the VVreſt, or the fingers.

The 1 Bender

The firſt *Bender* is called *Biceps* [Tab. 18. fig. 1, 2, 3. and Tabl. 10. fig. 1, and 2 A] or the double-headed muſcle, becauſe it hath a double beginning and theſe very ſtrong ſtanding off one from another to giue way to the Nerue of the arme and the inſertion of the muſcles of the ſame. Theſe originals doe ariſe from the ſhoulder-blade, but are couered by the ſecond muſcle of the arme called *Deltoides*. [tab. 18. fig: 1 M at fig: 3, N they are vncouered]

The ſituation of this Muſcle is on the inſide of the arme, and in thoſe bodies that are fleſhy or brawny it may be perceiued vnder the skin before diſſection. Of theſe two originals the one is outward [Tab. 19. fig: 1 B] which is neruous and round, ariſing out of the vpper brow of the cup of the ſhoulder blade, and is deriued vnder the Ligaments of the ioynt of the arme and aboue the head of the ſame through a fiſſure or cleft made of purpoſe for this vſe.

The other originall [tab. 19 fig: 1 C] is partly Neruous, partly fleſhy, broader alſo then the other ariſing from the proceſſe of the blade-bone which is like vnto an Anchor, and led aboue the head of the arme a little vnder which head it is vnited with the former [tab 19. fig: 1 & 2 F] and ſo they make one thicke, ſtrong liuid muſcle almoſt rounde and furniſhed with right fibres.

A fleſhy portion accounted for a particular muſcle.

A fleſhy portion of this muſcle is inſerted into the middle of the Hande, where the bone hath a priuate aſperity by which it is lift vp. This portion (ſayth *Columbus*) to a man that is not ſharpe ſighted ſeemeth a diſtinct muſcle drawing the arme to the breſt, of which portion alſo *Veſalius* and *Laurentius* haue made mention, but not *Falopius* or *Archangelus*, but *Arantius* ſomwhat boldly propoundeth it for the eight muſcle of the arme and indeede departing from the arme and climbing ouer another muſcle it beareth the forme of a round and fleſhy muſcle, and a little aboue the ioynt of the cubit becomming more ſinnewy it endeth into a ſtrong, thicke, round and neruous Tendon, and being moderately dilated is inſerted into an inwarde eminence and protuberation of the *Radius* or *wand*, created onely for the inſertion thereof. It groweth alſo ſomewhat to the ligament of the Ioynt. [Tab. 19. fig. 1, E] This Muſcle as alſo the ſecond hath right fibers, wherfore with the ſecond it bendeth the cubit ſtraight inward.

The 2 Bendes

The ſecond *Bender* is called *Brachiæus* the muſcle of the arme [Tab. 18. fig: 2, 3, 4. tab. 19. fig. 1, 2, 3 D] It lyeth vnder the former is ſhorter then it and wholy fleſhy, and embraceth very cloſely the lower and middle part of the length of the arme vnto which alſo it groweth. It ariſeth from the bone of the arme in that place where the Muſcles of the arme are inſerted about the middle of the length thereof on the outſide. His beginning is fleſhy and twofold, [Tab: 21, fig: 2, 3, V] and in the middle reſembleth an obtuſe angle. Preſently after it becommeth thicker and groweth ſtrongly to the arme, and deſcending downeward fleſhily couereth the foreſide of the Elbow repreſenting a little hillocke, and is ſtrangely infixed or inſerted larger and more fleſhy into the forepart of the Cubite or Ell, and the *Radius* or Wande, and the Ligament of the ioynt, [tab. 21. fig. 2 ° fig: 3, °] to bend the cubit in a ſtreight line.

The third.

The third muſcle of the cubit or the firſt *Extender* called alſo the long muſcle [tab. 18 fig.

C, The insertion of the wormy muscles into the first bone of the Fingers.

def 3, portions of the tendons cut of neare vnto their insertion, whereof *d* is the insertion of the Muscle growing to the Tendons, *e* the insertion of the first muscle bending the Fingers, and *f* of the secor d.

b 2, the corner of the shoulder blade whereinto the fourth Muscle of the blade called *Leuator* or the heauer, noted in the tenne precedent tables is inserted.

c 2, the higher processe of the shoulder or the top of the shoulder.

k 2, the insertion of the vpper blade rider.

l 2, the lower processe of the shoulder blade.

m 1, 2, The outward neruous head of the muscle called *Biceps*.

o 1, 2, his neruous head.

p 1, 2, the coition or meeting of these two nerues

q 1, 2, the tendon of this muscle.

s 2, A part of the *Supinator* or the muscle which bendeth the hand vpward where it goeth from the arme vnto the cubit.

t 2, his broade tendon inserted into the appendix of the wand.

u 2, the beginning of the second muscle bending the foure Fingers.

A 1, 2, the *Biceps* or the first mu'cle of the cubite which hangeth vppon the fourth from his insertion.

B 1, 2, 3, the 2. muscle of the cubit called *Brachiæus*.

C 1, 2, 3, the 3 muscle of the cubite called *longus*.

E 1, the muscle in the palme of the hand whose broad tendon is at *μ*.

F 1, 2, the first muscle bending the foure Fingers hanging down in the second Figure.

G 2, 4, the second muscle bending the foure Fingers hanging in the fourth Figure, *β* sheweth his tendons.

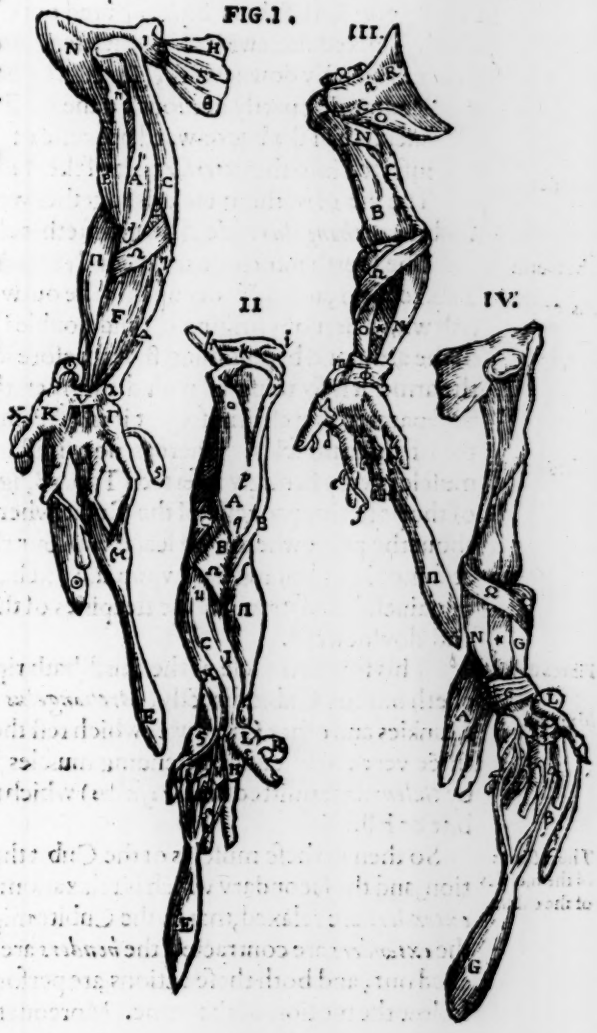
HH 2, the muscles called *Lumbricales*, their insertion are in the 4. Figure.

ſ 3, 4, the first of those that bend the thumbe, in the 4. it dependeth from his insertion, and his tendon is at *ε*.

Table 19. sheweth the Muscles of the Cubit, the Wand and the Fingers.

TABVLA. XIX.

FIG. I.



K 1, 2, the second bender of the thumbe. L 2, 4, the 3. bender of the thumbe. N 1, the muscle *Deltois* inuerted, the vpper N in the third Figure, the muscle called *Latissimus*, the tendon of the third muscle of the arme. The lower N in the 3, and 4. Figure; the *Vlna* or Ell without flesh. O, the vpper in the third Figure, the fourth greater round muscle of the arme. o, the lower 3, 4, the wand bared. Q 3, the vpper Blade rider whose insertion is at *ſ* 2, K. R 3, the Blade-lurker whose insertion is at *π*. S the vpper 1, the lesser Saw, *ν θ* his amplitude whereby it groweth to the ribbs. 1, the place where it groweth to the shoulder blade. S the lower 1, 2, the thicke muscle of the little Finger, or the fourth muscle of the extenders. X 1, the third extending muscle of the thumbe. X 2, the place where the muscle noted with G is diuided into foure fleshy parts. *β* 4, the tendons of the second muscle bending the foure Fingers. *γ* 2, the place where the tendons of the second muscle doe abide. *ſ* 2, the place where the tendons of the first muscle remaine. *ε* 2, the tendon of the first muscle bending the thumbe inuerted with the muscles in the hand. *ν θ* 1, 1, the amplitude of the greater Saw whereby it is ioyned to the ribs. *ν ν* 2, the muscles of the Fingers growing to the foure tendons of the second muscle in the hand which are called *Lumbricales* or the worme muscles. *ι*, 3, where it groweth to the angle of the shoulder blade. *λ* 1, the beginning and insertion of the bender of the wrist. *μ* 1, the tendon of the muscle of the palme of the hand. V 1, the transuerse ligament. *τ* 1, the muscle called *Interossei* or the slender muscle of the little Finger in the palme of the hand. *Δ* 1, The first muscle bending the wrist. *Θ* 1, The second muscle bending the wrist here hangeth downe. *Π* 1, 2, 3, the first *Supinator* of the *Radius* or wand, in the 3. Figure hanging from his implantation. *Φ* 3 4, the first *pronator* of the wand or the square muscle. *Ω* 1, 2, 3, 4, The round *Pronator* of the wand. Character 1, 2, 3, in the fourth Figure, the fourth 5. and 6. muscles bending the thumbe, * a ligament going betweene the Ell and the Wand.

fig.2,3,4.Tab.19,fig.1,2,3.and in the other figures at c] runneth fleſhy and with right fibres through the backſide of the arme. It ariſeth with a ſtrong and broade originall, partly neruous and partly fleſhy from the lower rib of the blade bone a little vnder his necke, where it hath a particular boſome or cau ty to couch it ſelfe in,and deſcending directly downeward,it groweth very fleſhy to the inſide of the arme, or rather it is increaſed with a fleſhy portion [Tab.21,fig.1,λ] bred out of the arme as it were with another originall, which is mixed therewith to giue it ſtrength: with which portion being augmented it deſcendeth directly downeward, (that fleſhy portion euen to his end growing to the arme) and becomming partly neruous on the outſide,partly fleſhy on the inſide,is inſerted into the inner ſide of the backe-ward proceſſe of the Cubit called *Olecranon*; *Archangelus* ſaith it is inſerted into the *exterior* part of the *Radius* where it hath a cauity inſculped for it.

His originall.

Augmentatiõ

Inſertion and vſe.

The vſe of of this muſcle is together with that that followeth directly to extend the Cubit; *Archangelus* addeth that it liſteth it alſo vpward.

The fourth.

His originall.

Progreſſe.

Inſertion.

The fourth muſcle or the ſecond *extender* called alſo the *ſhort* muſcle, [Tab.18,fig.4. Tab.20,fig.1,and 2,ρ] occupieth the outward part of the back-ſide of the arme. It ariſeth with a neruous originall, (and double ſaith *Columbus*) from the backſide of the neck of the arme and becom.ming fleſhy before it hath ouercome the middeſt of the length of the arme it is ſo mingled with the former that euen vnto the inſertion it can by no means be ſeparated therefrom, ſo that it may ſeeme to be but one muſcle or one body compacted of three muſcles, whereas notwithſtanding in truth they are two; for this fourth muſcle is very ſtrongly inſerted [Tab.18,fig.4,x Tab.20,fig.1, and 2,x] into the outſide of the poſterior proceſſe of the Cubit,where it is partly fleſhy, partly neruous,eſpecially about the point wheron we leane with our elbowes,which ſinewes haply is the reaſon why at ſome times leaning hard vpon the pitch of the elbow,we find a kind of benummednes or painefull ſenſation like the ſleepines of the legge to run along our arme both vpwarde and downeward.

Fibres & vſe.

Munkies.

This fourth muſcle as the third,hath right fibres, wherefore alſo it extendeth or ſtretcheth out the Cubit directly, *Archangelus* addeth alſo downeward. But in dogges and Munkies and other Creatures which reſt themſelues much vpon their forefeet, there are three very conſpicuous extending muſcles,beſide one very ſmall,found in Munkies (but by *Galen* pretermitted ſaith *Veſalius*) which runneth from the ſhoulder-blade to the Cubite or Ell.

The actions of the muſcles of the cubit.

So then in theſe muſcles of the Cubit the primary action is euident, which is contraction,and the ſecondary which is relaxation:when the *bending* muſcles are contracted,the *extenders* are relaxed,that ſo the Cubite might be inflected with more eaſe: againe,when the *extenders* are contracted,the *benders* are relaxed that the Cubite might be better ſtreched out, and both theſe actions are performed by right motion. By accident alſo they follow the motion of the arme. Moreouer,the Cubite is moued ſidelong and round.

CHAP. XXVI. *Of the Muſcles of the Radius or Wand.*

The motions of the *Radius* double.

THE motion of the *Radius* or *Wand* is double,for either it is moued *perſe,of it ſelfe* (the Cubit or Ell being vnmoued) by reaſon of the ioynt eyther aboue with the arme,or below with the wriſt, or both aboue and below with the articulation of the Ell; and ſo the whole hand is mooued eyther downeward or vpward, (for the whole hand being ſuſtained almoſt alone by the *Radius*, hath one and the ſame motion,and therefore is turned vpward by the aſsiſtance of two externall muſcles; and downeward by two internall, by which alſo it is turned about.) Or it is moued by accident with the Ell in a right line when the whole Cubit is bent and extended. There are therefore foure muſcles of the *Radius*, two called *Supinatores* which turne the palme of the hand vpward, and two called *Pronatores* which turne the palme downeward.

The firſt Supinator.

The firſt Supinator which is the ſecond of the Wand according to *Veſalius* (who calleth it alſo the *exterior*) *Fallopius* and *Platerus*,is alſo by *Laurentius* called *Supinator longior*, [Tab.18,fig.1,2,3,and Tab.19,fig.1,2,3.and Tab.20,fig.1,2,4,π] becauſe in reſpect of his belly it is the longeſt of all thoſe muſcles which run along the Cubit. It ariſeth fleſhly from the edge of the outward and vpper protuberation of the arme, [Tab. 19, fig.2,s Tab.20,fig.4,α] afterward being dilated it is bedded obliquely vppon the Wand, and is inſerted,growing broade at his Tendon into the membranous appendix of the *Radius* toward

A, 1, 2. A part of the muſcle called *Biceps*, or the double-headed muſcle.

B, 1, 2, 4. The higher and outward part of the muſcle called *Brachiæus*.

C, 1, 2, 4. the muſcle extending the Cubite from the lower part of the ſhoulder-blade, others call it the fifte muſcle of the Cubit.

D, 1, 2. The ſhort muſcle extending the cubit ariſing from the neck of the arme.

E, 1. The ſecond or the two-horned muſcle bending the wriſt.

M 1, 2, 3. the muſcle *Deltois* or the ſecond of the arme.

N 3, 4. The Ell without fleſh.

O, 1, 2. the fourth muſcle of the arme called *Rotundus maior*.

O 3, 4, the Wand bared a great way.

P 1, 2, 3. the lower blade rider or the fift muſcle of the arme.

The lower P in the 1 and 2 figure. the firſt extender of the foure-fingers, in the ſecond figure hanging downe, whoſe originall is at *a* and tendons at *b*.

Q 1, 2, the 2 muſcle extending the foure fingers, in the 2 Figure hanging downe.

R 2, 3. the thirde extender of the forefingers in the third Figure hanging down clouen into 2 parts at *op* in the 2 Fig.

S, I, the 4 muſcle extending the forfingers

T, the vpper, the fyrſt muſcle extending the thumbe.

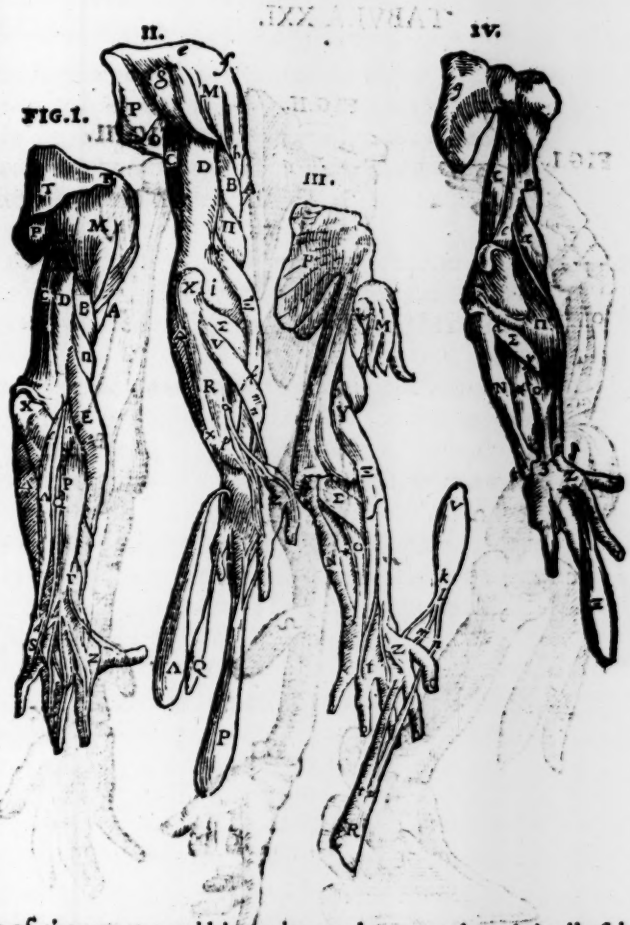
V, 2, 3. the 2 extending the thumb.

Y, 3, the originall of the 2 muſcle extending the wriſt.

Z, 1, 2, 3, 4. the 4 extender of the Thumbe

a, b, 1, 2. the originall of the firſt extender of the foure Fingers from the protuberation of the arm at *a* and his tendons at *b*. *a* 4, the originall of the ſhorter ſupinator of the Wand. C 1, the originall of the fyrſt extender of the wriſt from the vpper protuberation of the arme. C 1, Another part of the long extender of the cubit. *d* 1, His inſertion at the little Finger. *e* 2, the ſpine of the blade & the top of the ſhoulder. *f, g*. the originall of the Cowle muſcle in the hinder part from the ſpine of the blade. *b* 2, His inſertion. *i* 2, the membranous Ligament of the Wand, tying the vpper part to the arme. *i, k, l, m, n*, 2, 3. The vpper part of the ſecond muſcle extending the thumb marked with V. inſerted into the bone of the wriſt at *k, l*, the lower part diuided into two at *l*, the one vnder the wriſt bone that ſuſtaineth the thumbe at *m*, the other inſerted into the thumb at n. *op* 2, The thirde extending muſcle noted with R cut into two parts. *q* 4, the backe of the ſhoulder blade bare. *r* 2, the originall of the ſecond extender of the wriſt. *ſ, t* 3, the original of his horned tendon *ſ*, the inſertion *t*, *x*, 1, 2 A place of the Ell without fleſh. Δ 1, 2, the firſt bender of the wriſt. Λ 1, 2, the firſt extender of the wriſt. *w* in the 2 Figure hanging, whoſe originall is at *c* and inſertion at *d*. Π, 1, 2, 4. the fyrſt ſupinator of the wand whoſe beginning is at *α* inſertion at *β* in the 4 Figure. Σ 2 3, 4. the ſhorter ſupinator of the *Radius*, whoſe beginning at *α* his inſertion at *γ*. Ξ 2, 3, 4, the ſecond muſcle extending the wriſt. *α, β* 4, the beginning of the fyrſt ſupinator of the wand from the arme at *α*, whoſe inſertion at *β*. *γ* 4, the inſertion of the ſhorter ſupinator of the wand. *δ, ε* 4. A place where certaine boſoms are prepared for the tranſporting of the tendons, and containing a griſtle of that place. ζ. 4, Ligaments ioyning the bones of the Wriſte together. *3, 4. A Ligament in the middeſt betwixt the Ell and the Wand.

TABVLA. XX. *Sheweth the extending Muſcles of the Arme, the Cubit, the Wand and the Fingers.*

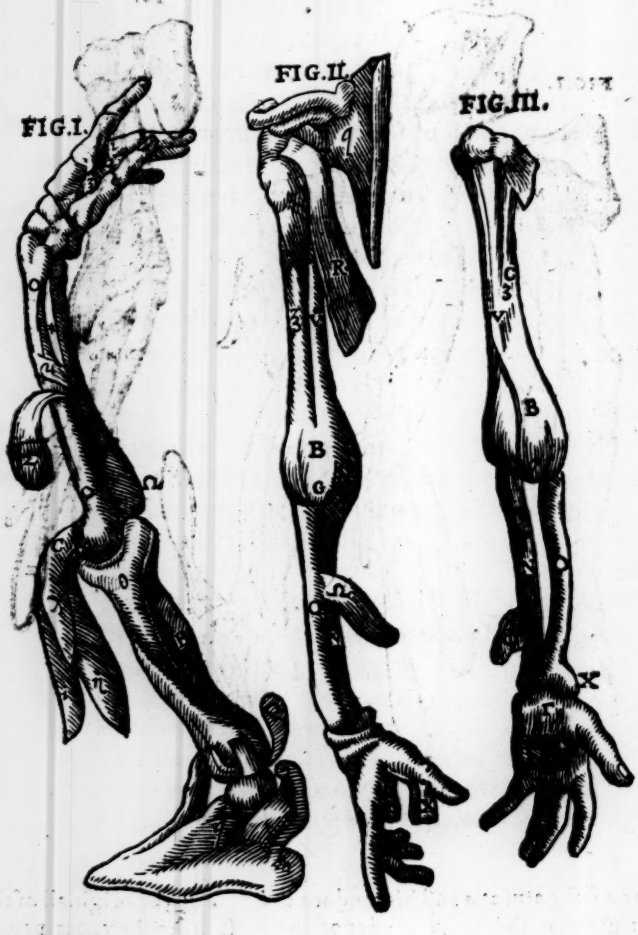


ward the inſide. [Tab. 19, fig. 2 ε and Tab. 20, fig. 4 β] This Muſcle ouet-turnes the lower part of the wand, and ſo lifts the p lm of the hand vpward.

The ſecond ſupinator which is the ſhorter [Tab. 20, fig. 1. 3, 4. and tab. 21, fig: 1 Σ] ariſeth fleſhy. *Platerus* and *Archangelus* ſay from a ſtrong Ligament which bindeth the cubit to the arme and from the vpper part of the *Radius*. *Bauhine* from the ioynt which articulateth the cubit to the arme, and from the backward proceſſe of the Ell [Tab. 20, fig. 4 α] which is called *Olecranon*: from thence it paceth obliquely and is implanted almoſt into the middeſt of the wand, to which alſo it adhereth [Tab. 20 fig: 4 γ] and it is on the outſide membranous and on the inſide fleſhy. This muſcle turneth the vpper parte of the wand obliquely outward and turneth vp the backpart of the hand. The ſecond

Table 21. Sheweth ſome muſcles of the Cubite, the Wand, the Thumbe, and thoſe we call interoſſei or bone-bound Muſcles.

TABVLA XXI.



q 1,2, The ſhoulder blade bare, & in the ſecond figure is his *interior* part.

b 1,2,3, The ſecond muſcle of the Cubit called *Brachiæus*, whoſe double originall in the third figure is noted with ν and his inſertion at ο.

C 1, Muſcles extending the Cubite which are accounted by *Veſalius* three, The third at ι the fiſt at μ & the fourth at λ.

G 2, The inſertion of the muſcle called *Brachiæus*.

N 1,2,3, The Ell bared from the fleſh.

O 1,2,3, the *Radius* alſo with fleſh.

Q 1. the vpper bladerider inuerted.

R 2, the ſame ſuperſcapularis hanging downe.

X 2, Two muſcles bending the ſecond ioynt of the thumbe.

Γ 2.3, One of the muſcles called *Interoſſei* applyed to the roote of the ſecond ioynt of the thumbe, but in the thirde figure are the *Interoſſei* in the palme of the hand, which fill the diſtances betwixt the bones of the Wriſt.

Σ 1, The ſhort Supinator of the Wand bending downeward.

Φ 3, The ſquare muſcle of the Wand bending downe.

Ω 1,2, the round muſcle of the Wand called *Pronator*, whoſe inſertion is noted with G. This in the ſecond figure is hung from his inſertion.

θ 1, the bone of the arme altogether without fleſh.

ιηλ 1, The firſt muſcle of the cubit at ι, the fourth at λ, the fiſt at η: or the three extending muſcles.

μ 1, The inſertion of the muſcle of the Wand called *Pronater* at Ω.

νζ ο,2,3, V, the originall of the ſecond muſcle of the arme called *Brachiæus*, on either ſide his inſertion in the ſecond figure at G, in the third at O, 1.2,3, char. 1, The fourth fiſt and ſixt benders of the thumbe, * Heere a ligament commeth betweene the Ell and the Wand.

The firſt *Pronator* which *Veſalius*, *Falopius*, and *Platerus* reckon for the firſt of the VVand, is called alſo by *Laurentius*, *Quadratus*, [Tab. 19 fig. 3,4, and Tab, 21, fig. 3,Φ] becauſe it ariſeth fleſhy, broade and ſquare, from the lower and inner part of the Ell neare the wreſt, and lying ouerthwart on the foreſide is inſerted with a membranous tendon, (*Columbus* and *Archangelus* ſay fleſhy) into the inner & lower part of the Wand. His fibres are trauſuerſe and clime vp ouertwhart from the Ell vnto the VVand. It is a large muſcle, and incompaſſeth al that part of the Ell and the VVand which lies directly againſt the inſide of the Cubit. It is ſquare and ſo long as the inner Region of the whole Cubit made of the Ell and the VVand. It is alſo euery way fleſhy, and in the middle thicke & bunching, ſeruing in ſtead of a ſoft pillow vnder the tendons that runne vnto the fingers. This muſcle drawing the lower part of the VVand which is next vnto the wreſt inwarde, beareth downe the VVand and the hand faſtened thereto into a prone poſition.

The firſt Pronator. — His fibres. — Figure. — Vſe.

The ſecond *Pronator* which is the third muſcle of the VVand according to *Veſalius*, *Fallopius* and *Platerus*, is by *Laurentius* called *Rotundus*. [Tab. 18, fig. 1,2,3, and Tab. 19, fig. 1,2,3,4. and Tab. 21, fig. 1,2. Ω] It ariſeth fleſhy from the inner protuberation of the arme and the inner ſide of the El where it is articulated to the arme, or as *Fallopius* hath it, from the inner ligament of that ioynt: thence it climeth obliquely ouer the inſide of the VVand and is implanted with a fleſhy inſertion about the middle thereof, [Tab. 20, fig. 4 5.] from this inſertion it runneth out neruous to the very middeſt of the VVand, and is infixed very ſtrongly with a neruous Tendon to a certaine roughnes that is in the vpper part

The ſecond Pronator. — His originall progreſſe. — Inſertion.

part thereof. [Tab. 21. fig. 1. μ] As often as this muſcle is contracted it leadeth the vpper part of the wand inward, and ſo wreſteth the VVand and the whole Hand into a proane and downward poſition.

CHAP. XXVII. *Of the Muſcles of the Hand in generall.*

Galen conſidering the admirable frame and ſtructure of the Hand, becauſe it is as he ſayth the *Inſtrument of Inſtruments*, intreateth of it in his firſt Booke *de vſu partium*. *Columbus* in the laſt place, becauſe (ſayth he) the wonderfull and miraculous frame thereof might remaine infixed in our memories, but we will diſcourſe of the Muſcles thereof in this place, becauſe we will follow the order of diſſection.

Seeing therefore that the proper action of the Hand is Apprehention, and Apprehention a Motion depending vpon our will, it was alſo neceſſary that the hand ſhould haue muſcles which are the inſtruments of voluntary motion whereby it might be mooued altogether and euery finger apart. The muſcles of the hand double.

The muſcles therefore which moue the hand are of two ſortes, ſome haue the guide of the motion of the whole Hand, others moue the Fingers onely. The former are likewiſe of two ſortes; for ſome doe either bend or extend the VVriſt, and conſequently the Hand with the ſame motion, others mouing the *Radius* or VVand do together alſo turne the Hand downward or vpward.

Theſe Muſcles are ſeated vpon the cubit either on the outſide or on the inſide. Hither alſo may we referre that Muſcle that moueth the skin which is in the palme of the Hand. Theſe that moue the Fingers doe either bend them or extend them or moue them ſidelong, that is, ioyning them together or parting them aſunder.

But becauſe the thumbe which is called *Pollex*, for that it is æquipolent or æquivalent to the whole Hand, hath in his bending and extending ſomething peculiar to himſelfe, differing from the ſame motions in the other foure Fingers, therefore it hath his peculiar Muſcles, as alſo the reſt of the Fingers haue theirs, whereof ſome are ſeated in the cubit, others in the After-wriſt and others in the ball or palme of the Hand. The reaſons of the motions from the articulations.

Againe, becauſe the articulation is diuers in the firſt ioynts of the fiue Fingers and in the ſecond of the Thumb, from that it is in the ſecond and third ioynts of the foure Fingers and the third of the Thumbe, becauſe the latter are ioyned by *ginglymos* the vpper bone receiuing into his boſome the protuberation or ſwelling of the lower, and the lower bone into his cauity the heads of the vpper: hence it commeth to paſſe that their motion is onely ſimple, abſolued by extention and flexion without any inclination to either ſide: but the firſt bones of the foure fingers and the firſt of the thumbe being faſtned by a ſame articlation to the bones with which they are ſuſtayned, are not onely bent and extended, but inclined alſo to the ſides as they are led to-ward or fro-ward the thumb.

I could buſie my ſelfe and you too in ſetting downe each Authors diuiſion of the muſcles of the Hand, for euery one almoſt differs from another, but becauſe the Hiſtory that followeth dependeth moſt what vpon *Bauhines* relation, therefore we will remit him that is deſirous to know each mans minde vnto their proper diſcourſes, & content our ſelues with *Bauhine* alone.

In the whole ſumme therefore the Muſcles which mooue the Hand are forty; foure of the wriſt, foure of the wand, of the palme of the hand three ſometimes foure, and 29. of the fingers. 40. muſcles of the hand. How ſeated.

Some of theſe Muſcles were ſeated in the cubite becauſe it was very neceſſary they ſhould be large, and their tendons onely are tranſmitted vnto the fingers. For if they had beene placed in the Hand they muſt needs haue increaſed the bulke thereof to that quantity which would haue been preiudiciall to the vſe of ſo excelent an organ. Notwithſtanding ſome are ſituated in the Hand.

Of theſe Muſcles there are nine benders, two bend the foure fingers and ſeauen the Thumbe. The extenders are 20. ſixteene extend the 4. fingers, in which number are thoſe foure called *Lumbricales* the VVormy muſcles, and thoſe eight called *Interoſſei*, becauſe they lurke betweene the bones. The other foure extenders doe ſerue the thumbe which they doe either ſimply extend or leade to the fingers or from the fingers, the tendons of which foure muſcles as *Galen* obſerued in the 17. chapter of his ſixt Booke *de vſu partium*, are infixed in the ioynt of the bone that is to be moued. But becauſe in diſſec- The vſe of the 40. muſcles.

tion wee meete firſt with the muſcle which is called *Palmaris*, therefore in the firſt place we will intreat of it.

CHAP. XXVIII. *Of the Muſcle of the Palme, and 2. or 3 other, iſſuing from the fleſhy Membrane.*

THE Muſcle of the palme ſo called by *Laurentius* and *Bauhine* lyeth vppon all the interior Muſcles of the Hand. [Ta. 22. fig. 1. 2. Ta. 23. fig. 1.] It is ſeated in the cubit and is neruous and round, ariſing with a neruous beginning from the ſharpe poynte of the inner protuberation of the Arme; leaneth vppon and groweth to the middeſt of two muſcles which bend the wriſt, [Ta. 22. fig. 1. ∆ ⊖] and proceede out of the ſame protuberation with it. Preſently after his originall it becommeth fleſhy, yet is the belly of it but ſmall, and before it attaine vnto the middle of the cubit it paceth ſomewhat obliquely, afterward it is againe attenuated and groweth ſmall or ſlender and determineth into a round, narrow, and long tendon [Ta. 23. fig. 1. μ] which riding ouer the inner Ligament of the wreſt, paſſeth vnder the skinne, and his tendon in the ball or palme of the Hand is dilated, attenuated and groweth to the skinne, yet ſo that it lyeth not vnder that part of the skinne which couereth the muſcles in the hillocke of the thumbe [Ta. 22. fig. 3. vnder p] and thoſe which leade the little finger from the reſt. [Tab. 22. fig. 1. and 3. S] Finally, it is ioyned with ſo ſtrong and fibrous tyes to the rootes of the Fingers, that although there be a certain fat, or ſubſtance like vnto it, (of which *Galen* maketh mention) comming betweene, yet you can ſcarce ſeparate the skin of the hand from the ſinewy thinneſſe of this Tendon.

His original

progreſſe.

Inſertion.

Vſe. The vſe of this muſcle is firmely to corrugate or contract the skinne of the palme when we would hold any thing faſt, for by that meanes the skinne becommeth immoueable, which if it ſhould moue, we could not hold a thing ſo ſteddily or ſo ſafely. Haply alſo this Tendon is the cauſe why the skin of the palme hath more exact ſenſe then the skin of the whole body: not that ſo quicke ſence is giuen to the hand by this Tendon, but becauſe of the foure nerues which run vnto the foure fingers.

[*Table 22. is the ſame with Table 18. Folio 778.*

Fallopius his obſeruation. *Fallopius* thrice or foure times found this muſcle ariſing out of the ſame place in each arme double, whereof one did end into a broade Tendon, the other was inſerted into the tranſuerſe ligament of the wreſt, on the contrary *Veſalius* ſaith that hee found more then once the fleſhy part thereof wanting, and then the broade Tendon was made of a portiõ of thoſe Tendons that bend the wreſt, [Tab. 22, fig. 1, ∆ ⊖] before they aſcend vnto the ſame. Sometimes alſo (ſaith *Bauhine*) the broade Tendon is produced from an interall tranſuerſe ligament which runneth ouer the Tendons of the wriſt, which alſo *Columbus* obſerued in the diſſection of ſome theeues.

A muſculous ſubſtance ariſing from the fleſhy pannicle. Beſide this muſcle of the palme in the beginning of the inſide of the hand at the lower part of the hillocke called by ſome *Mons Lunæ*, by ſome *Mons Martis*, by others *Veneris*, but we will cal it the Mountaine of the Moone, where the eight bone of the wriſt is ſeated, there is found a certaine fleſh. It proceedeth out of the fleſhy pannicle, or from the membrane of that muſcle which frameth the foreſaide Mountaine of the Moone.

The formes of it. This fleſh carrieth the forme ſometimes of two, ſeldome of three ſlender and ſhort muſcles.

The fibres. It hath tranſuerſe fibres and runneth to the middle and inner part of the ball of the hand, and is implanted at the broade Tendon of the palme muſcle, where it receiueth a complication with the fleſhy panicle which in that place is fatty.

His vſe. The vſe of this fleſh is in great contractions of the palme to draw the Mountaine of the Moone to the middle of the hand, when wee would make it as hollow as wee can, or elſe to binde in the two hillocks at the thumbe and the little finger for the ſame vſe. Of this muſcle, if ſo you will call it, none of the Ancients made mention, but it was firſt found by *Iohannes Baptiſta Cananus* & firſt deſcribed in print by *Valverda* who yet miſtaketh the vſe, for he ſaith it was made for extention.

CHAP. XXIX. *Of the ſubſtance which commeth betweene the skinne of the palme and of the fingers and their Tendons.*

BEtwixt the Tendon and skinne of the Palme and the inner ſide of the fingers there appeareth a certaine fleſhy ſubſtance like vnto fat, of which it ſhall not be amiſſe a little to diſcourſe. Although the whitiſh colour it hath and the hardneſs do more reſemble fat then fleſh, yet we conceiue that it may more fitly be referred to a kinde of fleſh, as well becauſe it is full of ſinewy fibres,

as alſo becauſe there are many ſmall and threddy Veines diſſeminated there-thorough. Add alſo that though a man be neuer ſo much extenuated or conſumed yet there alwaies remaines ſome part of this ſubſtance, whereupon it is that *Galen* cals it fleſh, and the *Arabians* thought it to be a kinde of ſimple fleſh different from the body of a muſcle. It may be obiected how then comes it to be ſo hard? I anſwere, by the contaction of the bones and of the Nerious parts which lie vpon it, and therefore it is like the fat which ioyneth vpon the ioynts of the bones. The vſe of this ſubſtance is to be as it were a pillow or bed whereon the many propagations of ſinews might lie ſoft which were deriued from greater Nerues to make the hand of exquiſite ſenſe. Such a ſubſtance alſo is found betwixte the Tendons that bend the fingers and their skin, leaſt when we are conſtrained rudely to take hold of any hard ſubſtance the tendons ſhould be preſſed or otherwiſe offended, for which cauſe alſo it is very plentifull vnder the skin of the ſoale of the foote, yet it is to bee noted that there is leſſe ſtore of it about the Ioynts leaſt it ſhould hinder their *Motion*, eſpecially when they bend into an acute Angle.

That it is fleſh not Fat.

In like manner in the ſides of the Fingers, there is ſome of this fleſh to fill vp the ſpaces betwixt the Ioynts which otherwiſe would haue bene hollow, becauſe the ſide knuckles at each bone doe ſtand ſomewhat out from the length of the bone, which equalitie was not onely made for ornament but rather and more eſpecially to make the Hande as we ſay thight, that is able to holde a liquid ſubſtance when we gather our Fingers toward the Palme to make *Diogenes* cup. Finally, this ſubſtance is very profitable in the toppes of the fingers for better apprehenſion, for if nothing had bene placed vpon the extremities of the bones which might yeelde a little when wee offer to take holde; ſurely the bones would haue bene in danger of breaking, and beſide wee could not haue gotten holde of many things which now we do by the helpe of this ſubſtance and the Nailes.

In what parts of the Finger this ſubſtance is.

CHAP. XXX. *Of the Muſcles which bend and extend the foreſingers.*

WE ſaide before that there were two Muſcles which did bend the foreſingers and 16 that did extend them. The firſt Bender [tab. 22. Fig. 4, ª] ariſeth with a round [ª] beginning and large, mixed of a fleſhy and Nerious ſubſtance, from the internall protuberation of the arme vnder the heads of the Palme-muſcle [tab. 22 Fig. 1 and 2ª] and thoſe two which bend the VVriſt, [Tab. 22 fig: 1, Δ, ⊖] Afterward becomming broader, it paſſeth thorough the middle and anterior part of the Ell and the VVand, and becommeth fleſhy and round, yet before it attaine vnto the roote of the VVriſte his Venter or Belly is anguſtated or ſtraightned, [tab. 22. Fig. 3 °] and diuided into four fleſhy pares, all which do determine into tendons exquiſitely nerious and tranſparant: and being together involued in one common, thin and mucous membrane; for their more ſafe progreſsion doe paſſe along vnder the annular or round Ligament [tab. 23 Fig. 1 V] which is ſeated ouerthwart the wriſt; and at the ſecond bone of the foreſingers nere the middeſt of the Ioynt are diuided with a long Section or ſlit through which the tendons of the next muſcle to be deſcribed (which lyeth vnder them) which were to reach vnto the third Ioynt are tranſmitted. There they become broader that they might mooue more eaſily and apprehend or take holde the better, and a little after the diuiſion or ſection they are inſerted into the ſecond bones of the foure Fingers. And truly this progreſſe and inſertion of theſe muſcles is an admirable and ſtrange worke of Nature: for they are ſo ſeuered, that the fingers in their motion might orderly follow one another, and each of them alone bend inward.

The 1 Bender of the foreſingers.

An admirable worke of Nature.

Moreouer, as they creepe vp the firſt bones of the Fingers they are rowled about againe with a tranſuerſe Ligament, which Ligament ariſeth out of the inner parte of the bone and maketh a kinde of Trough, wherein the tendon of this firſt bending muſcle, together with that of the ſecond muſcle vnder it, might ſecurely paſſe along the length of the Finger and holdeth it faſt leaſt it ſhould depart from his owne ſeate and ſo decline from his owne finger againe; that when it is contracted it ſhould not ſtrut or ariſe vp, eſpecially when we bend the ſecond or third ioynt of the fingers. For were it not for this tranſuerſe Ligament which ſtreightneth or bindeth the tendons in the place before named, they would not in their contraction bee curued backward but would ariſe vppe like right Chords, lift vp the skin and fill the ball of the hand, whereas the Ligaments althogh the tendons be contracted do yet keepe them cloſe vppon the bones into which they are not infixed, and ſo the way ouer the Ligament is ſmooth and euen.

The tranſuerſe Ligament.

The

The vſe of this Muſcle is primarily to bend the ſecond ioynt, ſecundarily alſo the firſt; becauſe in the paſſage they are firmely faſtened together by the interpoſition of membranes and fibres, and indeed the firſt ioynt hath no other Muſcle allotted for his flexion ſauing this onely.

the 2. *Bender.*

The ſecond *Bender* which *Laurentius* calleth *Muſculum profundum*, the Deep Muſcle, lyeth behinde the former [Ta. 23. fig. 2. 4.] being in his whole courſe, body and Tendons ſubiected vnder it euen to his inſertion. It ariſeth a little lower then the former from the proceſſe of the Ell on the foreſide thereof, [Ta. 23. fig. 2.] and is ſtronger then it, becauſe his motion is greater and of more moment. It is exactly fleſhy and broade, occupying the middle part of the cubite and groweth both to the Ell from which it taketh ſtrength, and alſo to the Ligament which ioyneth the Ell to the Wand, and ſeparateth the interior muſcles from the exterior; but when it is deſcended lower thē the middle of the cubit, it is anguſtiated or groweth narrower [Ta. 23. fig. 2. x fig. 4. e] and diuided into foure fleſhy partes which are couered with a neruous coate and by degrees bring forth neruous and round tendons which perforate or makeway through the Tendons of the former muſcle. All theſe Tendons paſſing vnder the tranſuerſe and membranous Ligament of the wriſt, are euery one of them in the ball of the hand inueſted with proper membranes which are ioyned to the Tendons by neruous tyes. Afterward they creepe vnder the foure Ligaments of the fingers, and paſſe thorough the holes or diuiſions of the Tendons of the firſt Muſcle, [Ta. 23. fig. 2. γ.] that ſo they may bee implanted into the third ioynt, yet a little before their inſertion they become broader, and in olde men there is found a little bone like the *Seſamum Seede*, or like that wherwith we feed Canary Birds, which hath the ſame vſe and forme that the Patell bone or whirle bone of the knee, for as theſe ſmall bones do grow to the tendons of the firſt muſcle, ſo they alſo growe to the Tendons of the ſecond muſcle before they are inſerted into the third bones of the fingers.

The vſe of this Muſcle is to bend the third ioynt of the foure fingers, yea which is more as *Aranzius* hath obſerued, it ſeemeth to contract twelue ioyntes, becauſe in his paſſage his tendons are affixed to the firſt and ſecond ioyntes by their membranous Ligaments. And indeed if we obſerue the motions of our hands well, when we would moue the third ioynt, the two former are curued whether we wil or no, whereas the third and the ſecond may be bent when the firſt is immouable and extended: and thus much of the Muſcles which bend the foure fingers.

The extending muſcles of the fingers, called *Vermiculares.*

The extending Muſcles are 8. beſide the *Interoſſei* of which wee ſhall intreat afterward: of theſe the firſt, ſecond, third and fourth [Ta. 23. fig. 2. ν.] are called *Lumbricales* or *Vermiculares*, that is, the wormy Muſcles, and doe cleaue to the ball or palme of the hand. They are fleſhy, ſmall, round and long, and doe lie vnder the tendons of the ſecond muſcle which bend the third bone of the foure fingers. They ariſe at the inſide from thoſe membranes of the Fingers which we ſayd euen now did inueſt the foure tendons: neither let it ſeeme hard that I ſay they ariſe from membranes, becauſe the muſcles alſo of the eie take their beginning from membranes. Afterward they runne along the finger on the inſide, and with a neruous and ſmall tendon they do adhere to the tendons of the Muſcle next to be deſcribed, which extendeth the foure fingers. Their inſertion is made about the middle of the firſt ioynt into the ſecond. Wherefore when theſe muſcles are contracted to their originals, the ſecond and third ioynts of the fingers, together with the help of the Muſcles called *Interoſſei*, are primarily extended, although the Fingers alſo are extended by accident, that in great conſtraynts they might ſerue to aſsiſt oblique motions. For becauſe the Tendons of theſe Muſcles in their paſſage to their exterior part of the Fingers are tyed to the laterall or ſide-ligament of the firſt ioynt, they are able alſo with a ſlender motion to leade the firſt knuckle vnto the thumbe: and becauſe the tendons of the next muſcle to bee deſcribed are ſeated on the outſide and therefore obnoxious to outward iniuries, Nature placed theſe on the inſide that if by miſhap the outward Tendons were violated or wounded, yet the fingers by the helpe of theſe might bee extended, and this is the manner of the poſition of the firſt foure extending muſcles.

[*Table 23. is the ſame with Table 19. Folio* 781.]

The 5. extender.

The fift *Extender* [Tab. 24. fig. 1. and 2. at the lower p which in the ſecond figure hangeth downe] ariſeth with an originall mixed of a fleſhy and neruous ſubſtance [*] from the outward protuberation of the arme. Afterward it becommeth more fleſhy, and deſcending

scending in the hinder part betwixt the Ell and the Wand, is neere the wrest above [b] much narrower, and for the most part cloben into three, rarely into foure fleshy partes, which presently degenerate into nervous Tendons exquisitely round for their better security; which Tendons are tyed together by a membranous ligament arising from the appendix of the Wand & so are together conveyed through a cavity exsculped or wrought in the externall part of the Wand into the wrest. And least these Tendons should at any time fall out of that cavity, or when the muscle is contracted, strut up as we see a broken veine doth, they are included with an annular or round ligament. [Tab. 22, fig. 3, and 4, charact. 3.] Presently after under the wrest they recede or depart one from another, remaining no more round, but becomming broad because the bone on the outside is round of it selfe: and one runneth into the second and third ioynt of the fore-finger, another of the middle finger, and the third of the Ring-finger. And hence it is that we feele so great paine if any thing get betwixt the nayles and the flesh. Sometimes it is divided into two Tendons onely, which are inserted into the fore and middle fingers.

Insertion.

The cause of peine vnder the naile.

The vse of this muscle is to extend the second and third ioynts of those three fingers. And the Tendons of it are long, for the bellies do not reach vnto the wrist, that the hand might be lighter and more slender for agility in his motion.

The vse.

The sixt *extender* [Tab. 24, fig. 1, and 2, ⁸] is slender and long, having a sharpe and nervous originall, which it taketh from the same protuberation of the arme with the former, afterward becomming fleshy it is mingled with the former vnto the middle of his belly, so that in their originall they seeme to be but one muscle. It passeth along the Cubit through a cavity common to the Ell and the Wand, and running vnder the transverse ligament is sometimes divided into two nervous and round Tendons, sometime it remaineth single. If double, one is implanted into the *posterior* part of three bones of the Ring-finger, the other becomming broader is fastened into the backepart of the 3 bones of the little finger.

The sixt *extender*.

His originall.

Implantation.

His vse is to extend these fingers and to leade them a little outward, especially the little finger.

Vse.

The seaventh *extender* [Tab. 24, fig. 2, and 3, ⁸] lyeth vnder the two former, & ariseth exactly fleshy from the middle of the Ell where you shall meete with a long and rough line made of purpose for the rise of this muscle: thence it descendeth obliquely vnto the *Wand* and climing ouer the appendix of the wrest is divided into two tendons, [Tab. 24, fig. 2, ⁹⁹.] which are transported through a proper cavity in the appendix of the *Wand* and vnder the transverse ligament. [Tab. 22, fig. 2, 3. charact. 4.] The vpper of these Tendons is inserted at the roote of the forefinger for the most part, more rarely at the roote of the thumb, the lower is inserted at the roote of the middle finger, sometimes onely saith *Fallopius* of the fore-finger: both their insertions are oblique, and indeed the whole course of the muscle is oblique. Their vse is to extend those fingers into which they are inserted: beside, that in extending the fore-finger, it also leadeth it from the Thumbe.

The seaventh *extender*.

His originall.

Implantation.

Vse.

The eight *extender* which is also the last, (not accounting the *Interossei* in this place) [Tab. 22 fig. 1, ⁵ and Tab. 24, fig. 1, ⁵] is seated within the hand. It ariseth short, strong, and fleshy from the fourth bone of the wrest, and passeth by the lower part of the *Afterwrist*, so ascending vnto the roote of the little finger to the outward side of the first bone, in which it is inserted slender and nervous. His vse is to extend the little finger, & withall to leade it from the rest of the fingers when we desire to comprehend any round forme as a Ball or a Globe in our hands. This muscle resembleth the fashion of a Mouse, because in the beginning and the end it is slender, but in the middest round and thicke.

The eight *extender*.

His originall.

Implantation.

Vse.

And these are all the eight extending muscles. There are also eight more *extenders* (for we reckoned sixteene in the end of the 27 chapter) called *interossei*, of which we will intreate in the next chapter saue one, because the method and order of dissection requires that we should first speak of those muscles that bend and extend the thumbe.

The *interossei*.

CHAP. XXXI. *Of the Muscles that bend and extend the Thumbe.*

WE saide before that there were seauen muscles which did bend the Thumbe, & foure that did extend it.

The first bender of the Thumbe, [Tab. 23, fig. 2, and 4. ⁵] is seated in the Cubit, and beareth vpon the second bending muscle of the foure fingers, [Tab. 23, ⁶] to which it is a little continuated at the ioynt betwixt the arme and the Cubit, but they cleave together in their whole progresse.

The 1 bender

It

It ariſeth with a round and fleſhy originall out of that part of the Ell which is nexte the ioynt of the Cubit where it receyueth the head of the *Radius* outward; and ſo it runneth along the wand to which it groweth throughout as if the whole length of the wande did miniſter vnto it a continuated originall.

Progreſſe. Moreouer, it getteth an additament or encreaſe by a portion it receyueth from the Membranous Ligament [tab.23.fig.4 *] & then running ouer the wriſt it determineth into a round and neruous tendon which together with the two benders of the foure Fingers creepeth vnder the annular Ligament of the wriſt to whoſe ſide alſo it is faſtened. In that place it is couered with a propper mucous or ſlimy membrane and is hidden betweene the muſcles which bend the firſt and ſecond bone of the Thumbe in a cauitie of a bone of the wriſt which ſuſtained the thumbe and hollowed onely for this tendons ſake. Munchies. Afterward it is receiued vnder the tranſuerſe ligament of the ſecond bone of the thumbe and dilated into his third ioynt where it is very ſtrongly inſerted and ſerueth to bend it. This muſcle is thicker then that which bendeth the ſecond finger, becauſe the thumbe is of greater ſtrength and magnitude then the reſt of the fingers. In Munkeyes (ſayth *Bauhine*) this Muſcle is not found, yet *Veſalius* deſcribeth a Subſtitute for it.

The 2. Bender The ſecond Bender of the thumbe [tab.23.fig.1 and 2 *] ariſeth fleſhy from the vpper part of the annular or tranſuerſe Ligament which is in the wriſt, [tab.23.fig.1 V] and is faſtened to all the inner region of the firſt bone of the thumb, to which alſo it is fleſhily inſerted, yet obſcurely it toucheth alſo the ſecond bone.

The 3. bender The third Bender [tab.23.fig.2 4.**] lyeth vnder the ſecond and is farre leſſe then it. It ariſeth partly out of the ſame place with the former, partly from that bone of the wriſt which lyeth vnder the thumbe and is inſerted into the root of the firſt bone of the thumb as farre as his middle. The vſe of 2 and 3. Theſe two laſt deſcribed muſcles doe bend the firſt ioynt of the thumbe and together with the third extender of the thumbe do make that mountainet or hillocke of fleſh which is ſeated at the roote of the thumbe.

The 4. bender The fourth Bender [tab.23.f.4.char.1,2,3. do note this muſcle with thoſe that follow next] ariſeth with a ſlender and broad originall from that bone of the After-wriſt which lyeth before the fore-finger, from thence it proceedeth fleſhy yet ſomewhat narrower, & is inſerted with a membranous tendon into that ſide of the ſecond bone of the thumb which is next the fore finger.

The fift. The fift Bender toucheth the former: is anſwerable to it in his originall, and being fleſhy proceedeth out of the middle part of that bone of the After-wriſt which lyeth vnder the middle finger. Some part of it alſo toucheth that bone which lyeth vnder the Ring-finger, and becomming fleſhy is inſerted with a ſmall tendon into the middle of the ſecond bone of the thumb on the inſide.

The ſixth. The ſixt Bender ariſeth ſomewhat broad from that bone of the After-wriſt which ſuſtaineth the ring-finger, and is inſerted into the ſame place with the former: ſometimes alſo it proceedeth with a neruous original from the bone of the After-wriſt which is vnder the little finger where it is ioyned with the wriſt.

[*Table 24. Is the ſame with Tab. 20. in fol. 783*]

The poſition of the 4. 5. 6. These three muſcles ſeated vnder the *line of life*, haue a ſemicircular and diſtinct original but yet do all determine into one and the ſame tendon which is tyed to the inner Seede-bone which alſo is the greateſt of all the ſeede-bones in the fingers, and is inſerted into the ſide of the ſecond bone of the ſame finger. And as thoſe muſcles which hereafter we ſhall call *interoſſei*, ſeated in the after-wreſt are carried directly or with a ſtraight line, ſo thoſe which bend the firſt bone of the thumbe run ſomewhat obliquely, and thoſe that bend the ſecond ioynt of the thumbe do run almoſt tranſuerſe or ouerthwart.

Their vſe. These Muſcles if they be contracted together doe mooue the ſecond ioynt of the Thumbe toward the ball of the Hand. If the firſt of the three mooue alone, the thumb is led vpward toward the fore-finger: if the ſecond it is led vnto the middle finger, if the third then is the thumbe bent downward and toward the little finger.

The ſeuenth. The ſeauenth Bender of the thumbe lyeth vnder theſe three laſt, and is fleſhy ariſing from the bone of the After-wriſt which ſuſtaineth the fore-finger below the middle, euen at the iuncture thereof with the wriſt. It is alſo ioyned as the three laſt mentioned, to the ſecond bone of the thumbe hauing a tranſuerſe poſition, and occupieth the ſpace which is betwixt the thumbe and the fore-finger. The vſe of it is to draw the thumbe toward the fore-finger and to lay it thereuppon. And ſo much of the Bending Muſcles of the thumbe.

The

The *extenders* of the Thumbe are foure. The firſt [Tab.24,fig.1,the lower [r]] ariſeth fleſhy from the outſide of the cubit at his rough line neare the membranous ligament [tab.24,fig.4,*] which ioyneth the cubit to the *Radius*, and paſsing obliquely toward the *Wand*, before it touch his appendix determineth into a round and neruous Tendon which attaineth vnto the hand through the cauity by which the by-horned muſcle of the wreſt doth deſcend vnto the ligament: and is inſerted into the whole length of the thumbe on that ſide which is next the fore-finger as farre as to the third ioynt. His vſe is, to extend the thumbe toward the fore finger, and to leade it from the wriſt, and therefore moueth it ſide-long.

The extenders of the thumbe. *The firſt.* *His originall.* *Inſertion.* *and vſe.*

The ſecond *extender* [Tab.24,fig.2,3,[s]] ariſeth fleſhy from the ſame line of the cubit after his length, and climing obliquely ouer the VVand, is diuided into two vnequal parts which cleaue one to another, and is ſeated in a proper cauity inſculped or ingrauen into the appendix of the VVand, and is inueſted with a peculiar ligament. [Tab.22,fig.2,and 4,charact.6.] The vpper part remaining a while fleſhy, determineth into a Tendon almoſt round, and is implanted into the vtter ſide of that bone of the wreſt which lieth vnder the thumbe. [t] The lower [l] is ſubdiuided into two fleſhy portions, both which doe end into a Tendon: one of them groweth very ſtrongly to the roote of the firſt ioynt of the thumbe: [m] the other with a membranous tie cleaueth cloſe to his ſecond and third bones. [n] His vſe is to extend the thumbe inward.

The ſecond. *His original.* *Diuiſion.* *Implantation.* *Vſe.*

The third *extender* [Tab.22,fig.4.[x]·Tab.23,fig.1,[x]·] ariſeth with a neruous original, which preſently after becomes fleſhy, from the inner part of the bone of the wreſt which ſuſtaineth the thumbe. After being carried downward, it is inſerted with a membranous Tendon into the firſt ioynt of the thumbe which it leadeth from the foure-fingers. This muſcle with the ſecond and third benders of the thumb maketh that fleſhy portion of the palme which is at the roote of the thumbe, wee commonly call it the brawne of the hand.

The third originall. *Inſertion.* *Vſe.*

The fourth *extender* [Tab.24,fig.1,2,3,4,[z]·] occupies the ſpace which is betwixt the the thumbe and the fore-finger. It ariſeth fleſhy, partly alſo ſinewy from the inner and backer part of the bone of the After-wreſt which lies vnder the fore-finger, and is fleſhily inſerted on the whole outſide into the firſt ioynt of the thumbe. Moreouer it tranſmitteth a membranous Tendon to the ſecond, which *Fallopius* in his *Inſtitutions* acknowledgeth he hath found, but in his obſeruations he ſaith he could neuer meete with it. This muſcle ſerueth for the laterall motions of the thumbe. It leadeth it alſo to, and layeth it vppon the fore-finger. And ſo much for the muſcles of the thumbe as wel *benders* as *extenders*. Now we proceede to the muſcles of the After-wreſt and wreſt.

The fourth originall. *Inſertion.* *His vſe.*

CHAP. XXXII. *Of the Muſcles of the After-wreſt and the wreſt.*

THE After-wreſt called *Metacarpium* or *Poſtbrachiale*, is a part of the hād ſeated betweene the wreſt and the fingers. It hath eight muſcles, for in euery diſtance betwixt bone and bone, there are two muſcles which are faſtened to the ſides of the bones and therefore are called *interoſſei*. Thoſe that ariſe from the bones to which they grow, are throughout fleſhy and run directly according to the length of the bones, creepe on the backſides of their fingers, and their tendons are mixed with the tendons of the foure firſt extending muſcles of the fingers which we called the VVorme-muſcles. Sometime this mixture is made before their inſertion, ſo that the wormy and bone-bound Muſcles do ſeeme to make but one broad tendon.

The After-wreſt. *The muſcles called interoſſei, that is, bone-bound.* *Their originall.* *Vnion with the wormy muſcles.*

They are a little gathered or bound together by the Ligament of the firſt ioynt, and run by the ſides to the outward tendons of the fift muſcle that diſtendeth the fingers, into which alſo they are inſerted and with them are the authors of the extenſion of the ſecond and third ioynt of all the Fingers; and becauſe they cleaue to the ſides of the fingers, it ſhould ſeeme they were ordained to part the fingers aſunder, and to leade them againe together.

Inſertion. *Vſe.*

Hence it is, that if a man be wounded on the outſide of the After-wriſt, he looſeth the motion of the firſt ioynts of the fingers, becauſe the muſcle which extendeth the finger is cut aſunder, yet the ſecond and third ioynts are ſtrongly and quickly extended becauſe theſe ſmall muſcles do remaine ſound. Theſe muſcles doe make the inward cauitie in the After-wriſt ſo plaine and equall (like as others do the ſame in the foote) that the particular

A note for Surgeons.

tular tendons of theſe muſcles may run directly to the performance of their offices vpon a ſmooth and ſoft bed. They are alſo by this meanes ſecured from the offence which they could not otherwiſe but receiue by the hardneſſe of the bones vnder them. Finally, they do not ſuffer thoſe muſcles, together with the fat placed aboue them, to bee exiccated or dryed but maintaine and cheriſh their moyſture.

The muſcles of the wriſt

The next part of the Hand is the wriſt called *Carpus* or *Brachiale*, and is in the midſt betwixt the Cubit and the After-wriſt. The motions of the wriſt are to be bent, to be extended and to be enclined to eyther ſide, wherewith alſo the reſt of the hand is mooued with one and the ſame motion, and all this is performed by the helpe of foure Muſcles, whereof two ſeated within do bend, and two extend which are ſeated without.

The firſt bender.

The firſt bender which is alſo the lower, [tab. 22. f. 1, 3, 4. and tab. 23. f. 1, & tab. 24. f. 1, and 2 Δ] ariſeth with an acute originall mixed of a fleſhy and neruous ſubſtance from the inner or lower protuberation of the arme, and being fleſhy ſtrengthneth himſelfe by adhering vnto the length of the Ell euen vnto the wriſte, and for retribution ſerueth the bone for a pillow, which vſe we eſpecially make of it when wee write, for then wee leane vpon this muſcle. Preſently after, that is to ſay at the very wriſt, it degenerateth into a fleſhy and neruous tendon which is implanted into the fourth bone of the wriſt called by *Galen Os Cartilaginoſum*, and to the Ligaments of that Ioynt it is connected and compaſſed about with a common Membrane. [ν is his beginning and Δ his inſertion]

The ſecond bender.

The ſecond Bender or the vpper [tab. 22 f. 1 and 2. and ta. 23. f. 1 and Θ] ariſeth from the ſame protuberation and deſcendeth obliquely after the length of the wand, but before it come to the roote of the wriſt it endeth in a ſtrong tendon which hauing ouer-paſte the inſide of the wriſt becommeth broader and is inſerted into the roote of the bone of the After-wriſt which ſuſtaineth the forefinger. It groweth alſo vnto the tranſuerſe Ligament.

The vſe of the two Benders.

Theſe two Muſcles if they worke together do bend the Wriſt forward, and ſecondarily the hand alſo: but when one of them onely worketh it moueth obliquely now vpward now downward that part of the wriſt into which it is infixed, yet it giueth ſome ayde to the two Muſcles which are ſeated without.

The firſt Extender.

The firſt Extender or the lower [Tab. 22. f. 4. and tab. 24. f. 1 & 2 Δ] ſeated betwixt the firſt muſcle of the wriſt and the fift extender of the Fingers, taketh his original aſwell from the roote of the externall or vpper protuberation of the arme, as alſo from the top of the cubite which it embraceth; it runneth through his length, and when it attaineth to the wriſt, it is infixed with a round, neruous and ſtrong tendon aboue the appendix of the Cubite into the bone of the After-wriſt which lyeth vnder the little Finger, and not farre from the VVriſt. Sometimes alſo before his Inſertion, it hath a Seed-bone growing to it.

The ſecond Extender.

The ſecond Extender or the vpper which is alſo called *Bicornis* or the two-horned Muſcle [tab. 22. f. 2, 4. ε and tab. 21. f. 2. 3, ε] ariſeth fleſhy with a broade beginning from the bony edge which is in the arme aboue the exterior protuberation [ta. 24. f. 3 ε]. It runneth vpon the wand and aboue the middeſt of it determineth into a thicke, ſtrong, and double horned tendon, whence it hath his name ſaith *Columbus* and *Archangelus*, and when it hath directly ridden ouer the wriſt, the one of them is inſerted into the firſt bone of the After-wriſt, which ſuſtaineth the fore-finger and into the extremity or ende of the VVand: the other is infixed into the ſecond bone of the After-wriſt, vppon which the middle finger leaneth. *Archangelus* ſaith that he hath often found this two-horned muſcle double, that is to ſay, two muſcles; one greater whoſe originall was neruous, & whoſe tendon ended below the ioynt of the arme into foure fingers. The other leſſe, whoſe originall was neruous alſo, but his tendon ended in the middeſt of the VVand. He addeth alſo that his tendons are firſt broade, afterward round.

The vſe of the 2. extenders.

Theſe two extending muſcles if they worke together, do bend the wriſt outward & extend it primarily, ſecondarily alſo the hand; and are holpen by a portion of the thirde muſcle which extendeth the thumbe. Secondarily alſo they leade the wriſt about when one in his motion immediately followeth another. But when one of them onely worketh, then diuers motions are produced: for if eyther they worke aſunder, or one of the benders worke together with an extender, it moueth the wriſt obliquely and to the ſide. And thus much of the muſcles of the After-wriſt and the wriſt, now we proceed vnto the muſcles of the Cheſt.

CHAP.

CHAP. XXXIII. *Of the Muscles of Respiration.*

THE Chest contayneth the Instruments or Organs of life: Life cannot bee maintayned without Respiration, neither can Respiration bee performed without motion; it followeth therefore that the Chest must needs be moued for Respiration sake. If it be demanded why Respiration is so necessary, we answere, because of the high and great heat of the Heart, which by the ayre attracted in Respiration is refrigerated and cooled, euen as a mans face in Summer is cooled by a fan that wasteth fresh ayre vnto it. Why the chest moueth.

Now the Chest is moued either by it selfe or by accident when it followeth the motion of the spine or Rackbones of the backe, for when the backe is bent the Chest is also bent with it.

It is moued by it selfe and with a proper and peculiar motion for Respiration sake, which Respiration is accomplished by a double motion of the Chest: which is dilated when Inspiration is made, that is, when we draw the ayre into our Longues and so coole the heat of our Hearts; or contracted in Expiration, that is, when the ayre is driuen back through the Rough artery for the generation of the voyce, and the sooty excrements are blowne away least the heart should be suffocaced by them. His different motions.

In these motions of the chest wee must consider notwithstanding, that in Inspiration the lower parts of the chest are dilated and the vpper angustated or straytned: on the contrary in Expiration the lower are constringed or straytned, the vpper dilated. And this was the reason why the Chest was not made of one bone as was the Scull, but of many, which also are ioyned together by gristles that their motion might be more pliant and easie. Why not bony.

But as the heart is moued with Naturall motion, so the Chest is moued partly with Naturall partly with Voluntary motion: with Natural; because in our sleepe it is moued Naturally not according to our Will. With Voluntary, for wee haue read of some that by reteining their breath haue hastned death vpon themselues. As for the Longues they follow the motion of the Chest especially to auoyde vacuity, as well in those that sleepe as in those that are awake. The kinde of motion.

Philosophers doe differ much concerning these motions, but because we haue already touched vppon their disputation in the tenth question of the sixt Booke, wee will not here Tautologize though haply we might say something now, because this Volume groweth far beyond that extent which was first limitted for it.

The Chest therefore needed Muscles for Respiration, Respiration is absolued by his Diastole or dilatation when we breath in, & by his *Systole* or contraction when we breath out. These Muscles are in all 65. on each side 32. that is to say, 22. *Intercostal* Muscles, 11. internall and as many externall, and one which is common to both sides called *septum transuersum* or the Midriffe. Of these we haue spoken before in the fourth and fift Chapters of the sixt Booke. How respiration is made. The number of the muscles of respiration.

There remaine yet the proper Muscles of the Chest, sixe on either side, vnlesse it please you to adde three more according to *Falopius*: Finally, the Muscles of the *Abdomen* (which helpe also our Respiration) are on each side foure beside the *Pyramidals* or Spirie Muscles, so that the whole summe will now amount to 71.

Of these some are Common, as the Muscles of the *Abdomen* which beside Respiration doe serue also for other purposes, others are Proper and serue for Respiration alone. But Respiration is double, one free or naturall, the other constrayned or violent. 2. kinds of respiration.

That we call Free which is done gently and easily, that is, when in Inspiration there is without constraint so much ayre drawne in as may suffice for the generation of vitall spyrits, and in Expiration when a part of the attracted ayre is againe gently returned for the generation of the voyce, and both these are wrought by the motion of the Midriffe alone. Free.

The first by the Contraction of the Midriffe wherein the end of the bastard ribs are gathered a little vpward, the lower and forward part of the Chest angustated or straitned and the backepart inlarged to the Racke-bones, the seauen lower ribbes parted as it were asunder and so the Chest dilated.

The second, when the Midriffe is relaxed or loosened, for then the Chest doeth easily fall with his owne waight. We call that Respiration constrained, when the Dilatation Violent.

or contraction of the chest is euident, that is, when in Inspiration the breath is drawne with violence or vehemencie, as it happeneth when the heart is too much heated: and in Expiration, when the ayre is forcibly blowne out; as when wee would speake or hallow aloude, when we would cough or sneese, or else when vpon expulsion it is retained when we would make vse of the midrise in duacuation of excrements or such like.

How the muscles moue.

This respiration is absolued by sixtie foure muscles assisted by the midriffe, yet so that in Inspiration fewer muscles do labour them in Expiration. In Inspiration, that which is called *Subclauius*, *Serratus maior*, *Serratus posticus superior & inferior*, and *Fallopius* his 3. muscles. The Intercostall muscles doe also conferre to this businesse, but that by accident onely. In Expiration more muscles are required, because we breath out with greater strength then we breathe in; these are called *Sacrolumbus*, *triangularis*, and all the Intercostalls; for the exteriour doe leade the lower ribs upward, and the interior the vpward ribs downeward. The eight muscles of the *Abdomen*, and haply in great necessities the muscles of the arm and the shoulder blades do lend their helping hands. The Intercostall muscles we will here altogether passe ouer, as also the midriff, because we haue spoken of them at large before. The muscles of the *Abdomen* we referre vnto the next chapter, here we will onely handle the proper muscles of the chest, which grow thereto. These are accounted by *Galen* eight, and so many they are indeed in Apes, but in men there are but sixe in either side commonly receiued, to which *Fallopius* addes three.

The position of the muscles.

Two of these muscles are seated before, the one called *Subclauius*, the other *Triangularis*, one occupieth the sides called *Serratus maior*; the rest lie vpon the back part, three in the backe, two called *Serrati postici*, and the third *Sacrolumbus*; three in the necke, and

Tab. 2 Sheweth the muscles especially of the chest, the head, and of the shoulder blade.

TABVLA XXV.

A, The fourth muscle of the Chest or the vpper & hinder Saw-muscle.

B, the 5 muscle of the chest or the lower and hinder Saw muscle.

a, b, A membranous beginning of the muscle of the *Abdomen*, descending obliquely downe from the spine of the backe.

C, the 1 muscle extending the Cubit at *c* his originall is from the necke of the arme, and from the lower basis of the blade at *d*.

E, the originall of the fourth muscle of the Bone *hyois* from the blade.

G, G, the outward intercostal muscles.

I, the Clauicle or Collerbone bared.

N the vpper, the 2 muscle of the arme cald *Deltos* Char. 4, 5, the beginning of this muscle.

N, the third muscle of the arme or the broad muscle separated.

O, the fourth muscle of the arme or the lower *Super Scapularis* or bladerider.

1, 2, 3 char: His originall at the basis of the shoulderblade at 1, 2 and his insertion into the ioynt of the arme at 3.

Q, the sixt muscle of the arme or the vpper *Super-Scapularis*.

X, The fourth muscle of the blade called *Leuator* or the heauer.

Z, The second muscle of the chest or the greater sawe muscle.

7. 7. Char. The ribs.

Γ, The sixt muscle of the chest, or the muscle cald *Sacrolumbus*.

Λ, The first muscle of the head or the splinter.

ΕΕ, the second muscle of the head or the insertion of the muscles called *complexi*.

Φ, The 2. muscle of the back or the longest muscle

Ω. The fourth muscle of the backe called *Semi-spinatus*.

those

theſe are they which we ſaid before were propounded by *Fallopius*. But by *Veſalius* are eſteemed to be parts of thoſe muſcles which occupy the necke and the back, but we come to the particulars.

The firſt proper muſcle of the cheſt is called *Subclauius*. [tab. 17, ᵛ· tab. 22, fig. 3, ᵛ·] The reaſon of the name is, becauſe it is ſeated vnder the coller-bone which is called *Clauicula*, for it filleth that ſpace which is betwixt the clauickle and the firſt rib. 1. ſubclauius.

This muſcle ariſeth fleſhy from the inner and lower part of the clauickle which is next to the rib, runneth obliquely forward, and is fleſhily implanted into the vpper part of the firſt rib which is ioyned to the breſt bone. His fibres are very oblique, yea almoſt tranſuerſe. The vſe of it is to draw the firſt rib vpward and outward, and ſo the cauity of the cheſt is dilated.

The ſecond muſcle is called *Serratus maior* or the greater ſaw-muſcle. [tab. 10, 17, 25. ᵃ] It is a large muſcle, ſituated in the ſide of the cheſt, broade alſo and euery way fleſhy. His originall is large and fleſhy from all the inner baſis of the blade, and towards the ribs it is dilated, coucheth vpon them, is tyed to the by fibres, and is inſerted as it were diuided into fingers into the eight vpper, ſometimes alſo into the ninth rib, before they do determine into their griſtles. And theſe inſertions of thes muſcles are acute or ſharp becauſe of the tendons which deſcend obliquely with points like the teeth of a Saw, to meet with the teeth of the oblique deſcendent muſcles of *Abdomen*, with which they are finger-fanged as alſo is the lower and backeward Saw. 2 Serratus maior.

The vſe of this muſcle is by the collection of his fibres in great and violent conſtraintes or endeuours to draw the eight ribbes outward, and ſo to dilate the cheſt. But in dogs and Apes it is not onely inſerted into the eight ribs, but implanted alſo in the tranſuerſe proceſſes of the fourth, fifth, ſixt and ſeauenth rackbones of the necke, or if you pleaſe it ariſeth therefrom.

The third proper muſcle of the cheſt is called *Serratus poſticus ſuperior* [tab. 25, ^] the vpper *backe-ſaw*. It lyeth in the backe vnder the muſcle called *Rhomboides* or the thirde muſcle of the blade, betwixt both the blades and aboue the firſt muſcle of the head. A little muſcle it is, and ariſeth broade and membranous from the ſpines of the three lower rack-bones of the necke and the firſt of the cheſt. Afterward it paſſeth a little obliquely vnder the blade, becommeth fleſhy, and being diuided into three parts is inſerted into the three diſtances of the foure vpper ribs. 3. Serratus poſticus ſup.

The vſe of it is to draw the ribs vpward, to which it is implanted by contracting his fibres, and ſo the cheſt is dilated and the hinder cauity thereof inlarged.

The fourth is called *ſerratus poſticus inferior*, the lower *backe-ſaw* [tab. 25, ᵃ] and ſeated almoſt in the middle of the backe vnder the broade muſcle that is the third muſcle of the arme. It ariſeth membranous, neruous, broade and almoſt quadrangular like a combe as the other, but broader then it from the ſpines of the two lower rack-bones of the cheſt, ſometimes of the three, ſometimes alſo from the vpper rackes of the loynes. Afterward it paſſeth ouerthwart and lyeth vpon the muſcles of the backe, and beeing increaſed with fleſhy fibres is inſerted at the diſtances of the foure lower ribs before they determine into griſtles. The inſertion is made into the ribs themſelues, and the muſcle at the inſertion diuided as it were into fingers. It is much broader in men then in apes and dogs and in dogs larger then in apes. 4. Serratus poſti. infer.

The vſe of this muſcle is to draw the three or foure lower ribs outward, and ſo doth dilate the lower part of the cheſt as we ſaide the ſecond muſcle did dilate the vpper part.

The fift muſcle is called *Sacrolumbus* [Tab. 10, [Γ] ſayeth *Laurentius* it ariſeth from the *Oſſacrum* and the ſpines of the *Lumbi* or loynes. This muſcle may be thought to be common as well to the cheſt as to the backe. It lyeth vnder the former, and ariſeth fleſhy from the backe part of the *holy-bone*, and the vpper and inner part of the haunch bone. Afterward it creepeth vpward faſtening it ſelfe to the tranſuerſe proceſſes of the rackes of the loynes, and as farre as to the lower racke of the cheſt, is mixed with the long muſcle of the backe, [tab. 10, at φ] ſo that a skilfull hand can very hardly ſeparate them, and therfore it is eſteemed but a portion thereof. [tab. 10, α, β.] A little aboue the lower rack-bone of the cheſt it departeth from the other muſcles to which it did grow, and becomming by degrees more ſlender, is inſerted obliquely with round tendons not altogether fleſhy produced from the outward ſide [ta. 10, γγ·] into ſixe protuberations of the lower ribs which are their rootes. From thence as *Fallopius* rightly obſerued, are produced ſixe new fleſhy 5. Sacrolumbus.

Fallopius his 6. new muſcles.

muſcles neruous both in their originall and inſertion, and are implanted into the ſixe vpper ribs: ſo that from the twelfth rib where this muſcle is inſerted there ariſeth a certaine tendon, which becomming fleſhy and climing vpward looſeth his fleſh againe and is infixed into the ſixt rib, carrying the reſemblance of a ſlender muſcle. In like manner from the eleuenth rib proceedeth another Tendon which is inſerted into the fift rib, and one alſo from the tenth which is inſerted into the fourth, one from the ninth into the third; finally, from the eight and the ſeauenth which are implanted into the firſt ribs.

All theſe Tendons doe reſemble diſtinct Muſcles, yet they are ſo commixed together and with the *Sacrolumbus* in the ſurface that they ſeeme to bee partes thereof whereas indeed they are not, ſo ſayth *Falopius* in his obſeruations. VVherefore when as the *Sacrolumbus* draweth the ſixe inferior ribs backward and therewith downward, it moueth alſo together with them the ſixe vpper foreſayde additaments which are called *anſulæ* or the handles, and ſo conſtringeth the Cheſt.

The 6. proper muſcle.

The ſixt proper Muſcle of the Cheſt hath his name from the forme and is called *Triangularis* or the triangular Muſcle, becauſe it conſiſteth of two long ſides & one ſhort. It is ſeated within the cauity of the Cheſt vnder the breaſt-bone: little it is and ſlender, & in ſome men eſpecially if they bee leane, there appeareth nothing fleſhy in it. In ſome parts it is like a neruous Membrane ſtuffed with fleſh.

His originall.

It ariſeth from the lower part of the Breaſt-bone and paſſeth obliquely vpward and outward, growing to the griſtles of the true ribs euen vnto the ſecond: and this is the reaſon why the *Intercoſtall* Muſcles and thoſe which are called *Intercartilaginei*, that is, betwixt the griſtles doe appeare diuers, becauſe of their diuers fibres. The vſe of this muſcle is to leade the griſtles of the ribs together, and ſo to conſtringe the Cheſt or to preſſe down the forepart therof ſo much as is neceſſary for Reſpiration, but in Dogs it is wholly fleſhy and occupyeth the whole ſide of the Breaſt-bone.

Falopius his 3. muſcles.

Falopius is of opinion that the firſt and third Muſcle are too weake to ſuffice for the eleuation of the Cheſt, for hee eſteemeth the ſecond rather to bee a moouer of the blade; and therefore he ſayth that there are three other muſcles which performe this office placed in the necke, which *Veſſalius* in his Apology accounteth for partes of theſe Muſcles which occupy the necke and the backe.

The firſt of theſe three ariſeth with a neruous beginning from the inſide of the tranſuerſe proceſſes of the 3.4.5. and ſixt Racke-bones of the necke; then becomming more fleſhy it is infixed into the firſt ribbe which it lifteth vp, and together with it the whole Cheſt.

The ſecond is called *Scalenus*, becauſe his figure is vnequally triangular, [Ta.29.λ Table 13.CC.] It ariſeth fleſhy from the tranſuerſe proceſſes of all the racke-bones of the neck, the firſt and the ſecond being ſometimes excepted, and hath a fleſhy inſertion into the firſt rib, ſometimes alſo into the ſecond. This alſo ſerues to lift vp the cheſt.

The third and laſt ariſeth from the tranſuerſe proceſſes of the fourth and fifth racks of the necke, and is implanted with a fleſhy termination into the ſecond ribbe ſometimes into the third, and lifteth vp the rib into which it is implanted.

By theſe three Muſcles therefore and the *vpper back ſaw*, *Falopius* conceiueth that the cheſt is eleuated. And thus much ſhall ſuffice to haue ſayde concerning the muſcles of cheſt. Now follow the Muſcles of the *Abdomen*.

CHAP. XXXIIII. *Of the Muſcles of the Abdomen or Pauneh.*

The order of the muſcles of the *Abdomen*.

THere bee tenne Muſcles which couer the nether Belly, on either ſide fiue called the Muſcles of the *Abdomen* which are placed in this order. Firſt do appeare two obliquely or ſidelong Deſcending and as many Aſcending, which haply may more rightly bee diſtinguiſhed if they bee called the oblique externall and oblique internall, for they all aſcend or deſcend equally as a mans eye pleaſe. Next two Pyramidall, after them two Right Muſcles, and laſt of all two Tranſuerſe or ouerthwart, ſo called according to the leading of the fibres which doe mutually deuide themſelues, as *rightly* ſo *obliquely* and *ſidelong*.

The oblique or ſidelong deſcending, or oblique externall Muſcles [Tab.26.A B] ſo called of their oblique fibres [Ta.26.H] are placed in the ſides: they are of a Triangle Figure, and amongſt all the Muſcles of the *Abdomen* the greateſt and the broadeſt. Theſe where they are more fleſhy proceede from the top of the haunch-bone, [Table 26.f] and from

from thence haue their ſtrength and firmeneſſe; more neruous they proceede from the ſhare-bone [Ta.26.ᵍ] where they are perforated, and membranous from the membrane ſpringing out of the Ligaments of the ſpondels or racke-bones of the loynes: and ſo riſe vpward and ending ſomewhat fleſhily do cleaue to ſeauen, ſometimes to eight of the lower ribs before they determine or end into their griſtles. Their ſituatiõ

That they doe ariſe from below it is manifeſt, becauſe by all mens conſent they ſerue to dilate the Breaſt and ſo helpe Inſpiration; and therefore they muſt end in the Breaſt and not ariſe thence from, becauſe it is a ruled Axiom that euery Muſcle draweth toward his owne originall not toward his inſertion. They are therefore inſerted into the great Saw-muſcle [Tab.26.ᵉᵉ Ta.27.ᵖ Ta.28.ᵒᵒᵒ] at the 6.7.8. and 9. ribs as it were with [Ta.26.ᵇᵇ] a Finger-fould, as alſo into the lower backe-Saw at the three loweſt ribbes: ſometimes they are ioyned to the Pectorall muſcle with a thin neruous Tendon. Forward they [Ta.26.ᶜᶜ] are carried with a broad neruous and membranous Tendon, and in the middle of the *Abdomen* doe ſo mingle themſelues at the white Line [Ta.26.ᵈᵈᵈ] that they make as it were a coate which ſpreadeth ouer all the *Abdomen*. Theſe Muſcles are ioyned alſo to thoſe vnder them by the interpoſition of a ſlimy ſubſtance like faſt glew.

This white Line [Tab.26.ᵈᵈᵈ. Ta.27.ᵉᵉ Ta.28.ᵘᵘ] is in the middle of the *abdomen*, bred out of the concourſe or meeting of all the Tendons of theſe muſcles except the *right*. For the Tendons of the oblique muſcles are ſo cloſely vnited, that it ſeemeth but one tendon, and the Tendons of the inferior oblique do grow to the tendons of the tranſuerſe where the right Muſcles doe ſeparate themſelues, and ſo meete in one line, into which alſo the Pyramidall or ſpiry Muſcles are implanted. The white line.

This Line beginning at the Sword-like Cartilage or the Breſt-blade neruous, paſſeth vnto the commiſſure or ioyning together of the ſhare-bones: aboue the Nauell it ſpreadeth it ſelfe broader, but below it is narrower and is therfore white, becauſe there is no fleſh or red foyle vnder it. It ſerueth tò hould together all the Muſcles as in a common end or termination, that ſo the right Muſcles might remaine in the right ſide and the left in the left, and neither bee halled ouer his limits. It hath alſo ſometimes Fatte lying vpon it. The vſe.

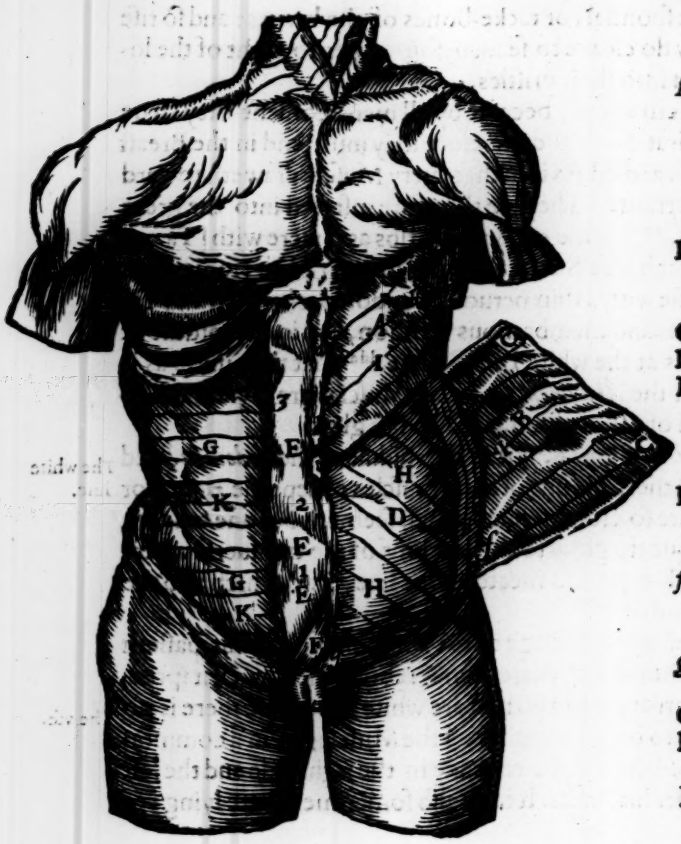
The oblique aſcendent [Tab.26.ᵖ Ta.27.i reflected from the *abdomen*] or oblique internall muſcles which doe interſect the former with their oblique aſcendent fibres like S. Andrewes Croſſe, or in the manner of the Greeke Letter χ [Table 26.ᵗᵗ] doe occupy the middle part of the *abdomen*, and are of a Triangular Figure. They ariſe fleſhy from the appendixe of the haunch-bone, and membranous from the membrane before named, & the ſpines of the Holy-bone, and being increaſed with fleſhy fibres and couering the hanches doe aſcend vpward, and becomming fleſhy are knit vnto the griſtles of the foure lower ribbes, and ſo are brought to the forepart of the *abdomen*, and end in a broad neruous and membranous Tendon: which when it meeteth with the right [Tab. 27.ᵇ] Muſcles is diuided into two tendons, one of which paſſeth aboue the *right Muſcle*, the other creepeth vnder it (for which cauſe *Galen* writeth that the right muſcles are not couered with any externall muſcle, meaning there by muſcle fleſh, for that that couers them is indeede but a Tendon:) ſo that by this imbracement the length of the right Muſcles is fortified and kept ſafe from ſolution or breaking, and as it were hemmed in the middeſt of three muſcles; where they do not as before couer the muſcle after the manner of a membrane, but doe ſo adhere to the interſections and partitions of the right Muſcles, that their tendon can be very hardly ſeuered from them. The oblique internall. Their original Their tendõs.

Being paſſed the right Muſcles, they againe mingle themſelues, are firmely and cloſly knit and vnited, and ſo goe hence away to the white Line [Ta.27.ᵉᵉ] framing as it were another membrane, and aboue doe meete with the ſword-like Cartilage or Griſtle of the Cheſt. Below they meete a little vnder the Nauel, but the vpper Tendon is inſerted into the ſhare-bones.

Theſe foure Muſcles haue Veines and Arteries from the *Muſcle-veine* and Artery, ſpringing about the Loynes which are diſſeminated through all the region of the *Abdomen* and the *Peritoneum* or Rimme of the Belly: they receiue nerues alſo from the laſt ſpondels or racke bones of the Cheſt, which are inſerted according as the leadings of the fibres are. Their veſſels.

The proper vſe of the externall oblique Muſcles is, when they worke together obliquely, to compreſſe the vpper and ſide parts of the lower belly on either ſide, and of the ob-

Table 26. Sheweth all the muſcles of the lower belly, on the left ſide the oblique muſcles, and on the right ſide the Piramidall, the right and the tranſuerſe.



TABVLA. XXVI.

A, The vpper part of the oblique externall or deſcending muſcle not ſeparated, wherein his connexion at *b b*, with the Saw-muſcle at *e e* is declared, and his implantation at C C into the white line at *d d*.

B B, The lower part of the oblique deſcending muſcle ſeparated from the white line at *d*.

C C, His tendon.

D, The oblique deſcending muſcle.

E E, the right muſcle on the right ſide, from which both the oblique muſcles are remoued, 1,2,3, The interſections of the right muſcles.

F, the *Piramidal* muſcle on the right hād, for both the left & the right pyramidal muſcles are vnder the oblique.

f, The fleſhy originall of the oblique externall muſcles from the haunch bone.

g, Their beginning from the ſhare-bone as alſo the *Piramidall* muſcles original.

G G, The tranſuerſe muſcle.

H H, The fibres of the oblique aſcending muſcle.

I, The fibres of the oblique deſcending muſcle that ſo the decuſſation may appeare.

K K, The fibres of the tranſuerſe muſcle.

oblique Internall in like manner to compreſſe the lower and ſide parts: but wee muſt not conceiue that all the lower belly is by theſe muſcles compreſſed, becauſe their Tendons reach but a little below the Nauill. The compreſsion is therefore made on either ſide but to the top of the groyne, for they are inſerted into the griſtly and moouable partes of the Ribbes.

The Pyramidall Muſcles, ſo called from their forme like a Pyramis or Broch, ariſing from the outſide of the ſharebone [Ta.26.' Ta.27,8] with a fleſhy and narrow beginning ſiding together like two parts of a ſpire, (for they are ſeldome ſo vnited that they make but one muſcle) doe clime with oblique fibres ouer the heads of the right muſcles from whom they are diſtinguiſhed by a peculiar membrane and different fibres; and do end in the white line (neuer in the right muſcles) with an acute tendon of their owne, but one longer then another; neyther in length exceeding the breadth of foure fingers: but theſe though they be moſt commonly ſeene in diſſections, yet in many bodies they are wanting, although *Fallopius* neuer diſſected body but he found them.

The Pyramidal muſcles

They are often wanting.

The vſe of theſe ſpiry muſcles is to compreſſe the bladder, for if one of them work alone, it draweth the white line obliquely downeward. If they worke together, they draw it directly downeward, and ſo compreſſe a part of the groine and the bladder therevnder, when we make water at leyſure. For if wee force our water with any violence, then the other muſcles of the *Abdomen* doe alſo helpe, preſsing the whole paunch & with it the bladder. And if we marke our ſelues in ſuch ſtrainings we ſhall manifeſtly perceiue, that the *Abdomen* is contracted downeward; and hence it is that they are alſo called *Succenturiati* the aſsiſtant muſcles becauſe they helpe all the reſt.

The vſe of the ſpiry muſcles.

And if at any time (as it happeneth but ſeldome) theſe pyramidall muſcles bee wanting, then the oblique aſcendents doe not take their firſt originall from the appendix of the haunch-bone, but lower from a ſtrong ligament which runneth from the aforeſaid appendix vnto the ſhare-bone, and then they vrge obliquely downeward what ſoeuer is vnder

der the groyne as is the bladder of vrine. They alſo adde ſtrength to the heads of the right muſcles to which alſo they ſerue as a defence. Whereuppon ſome haue imagined them (though falſly) to be another originall of the right muſcles. For if wee gently auoide our vrine neyther the inſpiration nor expiration is interrupted, which it certainely would be if they were parts of the right muſcles, becauſe when the right muſcles are contracted, the cheſt alſo is compreſſed, whence it would follow that when by the contraction of theſe muſcles we would exclude our vrine, we cannot draw in breath till wee remit or looſen the intention of the muſcles.

The right muſcles [Tab.26, [aa]. Tab.27, [a]. Tab.28, they hang downe and are marked with [aa]] haue their name both from their right fibres, and becauſe they are placed accor- The right muſcles. ding to the ſtraight length of the body: they are ſituated vnder the neruous thinneſſe of the oblique, and in ſome places ioyned vnto them: they occupy the higher place, where- Their tumors vpon their tumors being longer then round, may eaſily be diſtinguiſhed from the tumors how knowne. of other parts by their poſition. Their originall is neruous from the fore and vpper [Tab. 27, *bb*, Tab.28, charact. [a a]] part of the ſhare-bone, (not from the breſt becauſe the bones Their original of the ſhare, hips and haunches are not moued) but preſently they become more fleſhie, and inſertion. and climing ouer the belly about the nauill do ſeeme as it were to bee vnited [Tab.27, [f]] which yet is but the vicinity of their originall: but by how much they aſcend higher by ſo much are they more ſeuered [Tab.27, [e e]] and grow broader, and doe at length grow to the Cartilages or griſtles of the loweſt true ribs at the ſides of the breſt-bone with a fleſhy and ample inſertion. [Tab.27, [cc]] They are fleſhy and ſtrong the better to compreſſe Their interſections. the foreſide of the *Abdomen*, and haue three, ſeldome foure interſections or partitions very neruous and tranſuerſe or ouerthwart [Tab.26, charact. 1, 2, 3, Tab.27, [ddd]] as it were banked or knotted aſunder, ſo that they ſeeme to be not one, but many paire of right muſcles, diuided and diſtinguiſhed by the tendring or oblique bending of their fibres to theſe ſurfled interſections.

Theſe interſections are firme and ſolid membranes, whereof one is vnder the Nauill, two and ſometimes three aboue it; all which are ordained eyther to ſtrengthen the muſcle which is appointed for eſpeciall hard imployment, perticularly in deepe expirations; or elſe that being obliquated or *ſhelued* after the round figure of the *Abdomen* and faſtened with the tendons of the oblique aſcendents they might more cloſely preſſe the *Peritonæum*.

Table 27. Sheweth the Right, the Tranſuerſe, and the Pyramidall Muſcles.

TABVLA. XXVII.

A A, The right muſcles of the *Abdomen*.
bb, Their neruous originall.
cc, their implantation.
dddddd, their interſections.
ee, the white line where the right muſcles doe depart one from another.
f, the coniunction of the right muſcles vnder the Nauill.
g, The *Pyramidall* muſcles.
h, the membrane of the oblique aſcending muſcle which cleaueth faſt vnto the tendon of the trāſuerſe muſcle & ſo attaineth vnto the right muſcle.
i, the oblique aſcending muſcle here reflected from the *Abdomen*.
kk, the production of the *Peritonæum* or rim of the belly with the ſeede-veſſels.
lll, the tranſuerſe muſcles:
m, the groynes.
n, the circles which ſhew the bodies of the yard cut away.
o, the ſhare-bone without fleſh.
pp, the greater Saw-muſcle.
q, the leſſer Saw-muſcle.
rſſ, His amplitude and faſtening to the ribs.

They

um. They haue veines which we call *Recurrents*, and arteries from the *Epigaſtricke* [tab.28. ¹¹.fig.2.ᵇ] (from which alſo branches are ſent to the neck of the womb) diuided into many ſurcles or tendrils for their nouriſhment and life. VVhich being led vpward vnder their bodyes are about the nauell, [tab.28.fig.2.ᶜ ᶜ.] ioyned with the internall mãmary or pap [tab.28.fig.ˣ ˣ.fig.²•] veynes (which deſcend vnder the breſt bone) by *Anaſtomoſis*, that is, inoculation of their extremities.

Anaſtamoſis what it is.

VVhich *Anaſtomoſis* or kinde of vnion is the reaſon of the great conſent betweene the wombe and the paps, the *Abdomen* and the noſthrils. This conſent of the wombe with the paps, is alſo increaſed by certaine internal veins, one called the *Axillarie* which goeth vnto the paps, and by the branches of the *Hypogaſtricall*, which are diſtributed vnto the wombe. [*Tab.28. is the ſame with Tab.5. in the 2. Booke, fol.78.*]

They haue ſometimes foure nerues moſt what proceeding out of the middeſt of the laſt ſpondels or rackbones of the cheſt and ſo reaching to their hanked or ſurfled interſections or diſtinctions. Their proper vſe is to driue the higheſt and middle part of the lower belly not downeward but directly to the ſpine, to compreſſe it and to preſſe downe the lower parts of the cheſt by drawing them directly downeward. They helpe vs alſo in violent Expirations.

The vſe of the right muſcle.

The tranſuerſe or ouerthwart muſcle, [Tab.²⁶.° °. tab.27.¹¹¹· and tab.²8.ᵛ· a part of it is reflected,] is placed ouerthwart the belly, and ſo named from the tranſuerſe [tab.26. ˣ ˣ.] fibres which run through the bredth of their bodyes. Theſe are vndermoſt and doe ariſe neruous from the inward endes of the baſtard ribs, and the membrane twice before ſpoken of, and are inſerted, being become more fleſhy to the hanch bones, [Tab.28.ᵛ· where the hanche bones is bared, at which the tranſuerſe and oblique muſcles do meete and are implanted,] which after they haue inueſted and attained to the vtmoſt ſides of the right muſcles toward the middle of the *Abdomen* they couer all the reſt of it with a brode neruous and membranous tendon like that of the oblique muſcle, and tend vpward to the ſwordlike cartilage or breſt blade, forward to the right line and downeward to the groyne, and doe ſo cloſely adhere or cleaue to the *peritonæum*, that in a man they can ſcarſe be cleanly ſeparated from it, but in the groyne this *Aponeuroſis* or brode tendon forſaketh the *peritonæum* or rime, and leaueth it bare.

The tranſuers muſcles.

Their veſſels they receiue like their oblique muſcles. Their proper vſe is to compresouerthwart the middle and laterall part of the lower belly, and eſpecially the collicke gut. The tendons of theſe as alſo of the oblique muſcles are perforated at the exiture of the nauell to giue way to the vmbilical or nauel veſſels, & again, on both ſides neare the ſhare bone, that the preparing veſſels of ſeede may deſcend through them to the teſticles, and the eiaculatory may aſcend to the proſtates which are annexed to the necke of the bladder. Through theſe perforations [tab.28.ˣ ˣ.] the inward coate of the *peritonæum* being broken, or by ſtretching being dilated, the guts or the Kell ſlipping downe, cauſe the *Hernia* or Rupture. Beſide thoſe perforations common to both ſexes, they are alſo bored in women for the paſſage of thoſe ſinewy proceſſes which are called *Cremaſteres*, which doe reach vnto the vtter part of the lappe, whereupon women are troubled with the *Bubonocele*, and of it are cured by ſection.

That the tranſuerſe haue an inward ſituation, the right a middle, and the oblique an externall; a reaſon may be giuen from the Chyrurgicall deligations or ligatures, becauſe ouerthwart bandes doe preſſe or conſtraine more then right, and right more then oblique or ſide bands.

The reaſon of their ſituation from their vſe

All theſe muſcles of the *Abdomen* whoſe ſubſtance is partly membranous partly fleſhy that they might be ſtronger for motion haue this common vſe with other muſcles, that whileſt they are at reſt they ſerue for a muniment or defence vnto the parts ſubiected vnder them, beſide they contayne or hold the inward parts within their precinct, and keepe the body warme.

The vſe of the muſcles of the *Abdomen*. in generall

Particularly when they are together contracted toward their originals, and curued inward, the ſoft entrals giuing way vnto them, and are helped by the midriffe, depreſſed vpon the retention of the breath, then doe they equally and all ouer compreſſe the lower belly, (for if they worke ſeuerall, they preſſe ſometimes one part, ſometimes another) by which compreſſion the excrements which are violently thruſt downe into the great guts and there retayned at the fundament by the ſphincter muſcle are thruſt out by a recluſion or opening of the paſſage and a relaxation of that ſphincter, and there

thereupon they be called the inſtruments of Excretion by *Galen* in the 15. chapter of his fifth booke *de vſu partium*. But becauſe the compreſſion is equall from euery part, theſe excrements ſhould as well be preſſed vp to the ſtomach, as downe to the fundament, ſauing that the midriffe by his oblique ſituation and the breath retayned, doth driue them downward and helpe Excretion. They aſsiſt the Mother alſo in the time of the birth, by conſtringing or binding the *Hypochondria* and by drawing downe the ribs. They help alſo the motions of the Cheſt, for ſayeth *Galen* in the 14. chapter of the fift booke *de vſu partium*, they forme the voyce, ſerue to Inſpiration and Expiration and in ſtrong Efflations, as when a man windeth a Horne: yea ſayeth *Galen* they helpe vs alſo to hould our breath.

Wherefore becauſe theſe Muſcles doe night and day aſsiſt the breaſt in Reſpiration and the lower belly but at ſometimes when wee would vnburthen it, therefore they may be thought to be principally ordayned for the motion of the Cheſt. Againe, becauſe the Cheſt hath many other Muſcles which doe diſtend and contract it, but the lower belly theſe alone; it may therefore bee imagined that their primary vſe is to bee referred to the lower belly, their ſecondary to the Cheſt.

Finally, if each Muſcle worke by it ſelfe, then the oblique deſcendent drawes the haunch obliquely to his owne ſide, the right to the right ſide, the left to the left: the oblique aſcendent leadeth the cheſt obliquely to the haunches; the tranſuerſe drawes the paunch, the right into the right ſide, the left into the left. The worke of each muſcle alone,

It is alſo worthy obſeruation that the figure of theſe Muſcles whether they labour or reſt at quiet, is other and different from the figure of other muſcles: for theſe of the *abdomen* before they worke are crooked, & in their contraction hauing ſoft bodies vnder them they are bended or crooked inwarde: all other muſcles whileſt they are at reſt are right, when they labour they are curued and bent outward, becauſe of the bones againſt which otherwiſe they ſhould offend. And thus much of the Muſcles of the *Abdomen*: now we proceed vnto the backe. Their figure why differing from other muſcles.

CHAP. XXXV. *Of the Muſcles of the Backe.*

THe Muſcles of the Backe as alſo of the whole Spine are ſo diuers, ſo mixed and knit together, that ſome Anatomiſts haue deuided them into more, others into fewer muſcles, being led thereunto by reaſon of the infinite originals of the fibres and the multitude of their inſertions. All this variety *Aruntius* doth very wiſely aſcribe to the admirable wiſedome of Nature, who hath therefore intertexed and wouen one within another theſe Muſcles of the Backe, yea rather allowed them continual and indiuiſible particles, that they might the better ſuſtain and accompliſh thoſe ſtrong and violent actions ouer which they haue the commaund. For if power vnited be the ſtronger, then certainly if many muſcles doe conſpire together into one motion they will bee better able to abſolue it. The Muſcles therefore of the Backe together with the racke-bones were made to rayſe vp and there to hold the whole bulke of the body, which is eſtabliſhed vpon the holy-bone as vpon his foundation. We ſay therefore with *Galen* in the 24. chapter of his Booke *de diſſect. muſcul.* that becauſe theſe muſcles cannot by any meanes be truely ſeparated; either there muſt bee ſo many payres as there be racke-bones, or elſe we muſt ſay that there is one only paire offering tedinous diſtributions to all the *vertebra*. And of this payre if one Muſcle worke, the ſpine is extended and inclined into his ſide; when they both worke equally, the Spine bending on neither hand by reaſon of their intention or remiſsion is recurued backward. Why the muſcles of the backe are ſo wouen together. They haue no antagoniſts.

But whereas almoſt all Muſcles haue their Antagoniſts, that is, the authours of a contrary action to theirs (and therefore haue experience of their mutuall action and paſsion with an interpoſition of reſt in the middle figure) yet notwithſtanding theſe muſcles of the Spine (if you except the bending muſcles of the necke) haue no Antagoniſts or contraries.

For becauſe the inner Region of the Cheſt and the Loynes are deſtinated to thoſe moſt noble entralles which ſerue for Reſpiration or Nouriſhment, it ſeemed not good to Nature to aduenture to impeach their actions by any inſtruments of voluntary motion. Whence it is that when theſe Muſcles are relaxed (as they are in old men as well by reaſon of the waight and weakneſſe of the body, as alſo becauſe they abound with Phlegmatick humors) they are not able to containe or hold the body vpright. Notwithſtanding Anato-

Foure paires of the backe.

natomiſts, becauſe they haue obſerued eſpecially in Dancers and Tumblers, that the back is moued forward, backeward, to the ſides, and almoſt ſemicircularly, they haue reſolued that for the performance of theſe motions there are on either ſide foure muſcles, *Laurentius* maketh ten. *Siluius* but ſixe.

The firſt payre are called *Quadrati* the ſquare muſcles, [Tab. 17, Σ Σ, Tab. 11, & 29. Σ.] they ariſe broad, thicke and fleſhy from the backward and vpward cauity of the haunch-bone, and from the inner and vpper of the holy-bone, and lye as it were ſquare vpon the rackes of the loynes, vp which they climbe on the inſide of the *Abdomen*. There they are a little ſtreightened and cleauing to the tranſuerſe proceſſes of the rackes of the loines are fleſhily inſerted in the lower part of the twelfth rib.

The fibres of this muſcle do aſcend from without inward and obliquely vpward, and thoſe which proceede from the holy-bone are inſerted into the loweſt rack of the loines: the reſt of the fibres which ſucceede theſe toward the haunch-bone, doe by degrees determine into the vpper rackes, ſo that in the whole courſe of this muſcle the fibres are inſerted to the tranſuerſe proceſſes of the rackes of the loynes, and to their ſides.

Their vſe is to bend the rackes of the loynes or the lower part of the backe with the right motion forward, but if one of them worke alone, then is the flexion oblique and the backe drawne to one ſide and together forwatd. The forme of this muſcle in dogs and apes differeth much from his forme in men.

[*Table 29. is the ſame with Table 12. folio 770.*]

The ſecond payre called *Longiſſimi*, [Tab. 10, 11, 35] are indeed the longeſt muſcles in the whol body of man, for they reach from the lower end of the *holy-bone* vnto the firſt racke-bone of the cheſt, ſometime to the mamillary proceſſe of the temple-bones. They
Poſition. are like the fift paire of muſcles of the cheſt called *Sacro lumbi*, [Tab. 11, r] to which in their originall and their proceſſe thorow the loynes, they do grow as if they were a part of that paire. They are alſo the largeſt of all the muſcles of the backe.

They ariſe with a very neruous, ſtrong, and acute originall [Tab. 12,] from the top of the ſpine of the *holy-bone* [Tab. 11, t] paſsing through his length and from the ſpines of the fiue racke-bones of the loynes.

In the inſide of the haunch-bone [tab. 29, Φ] where they are ioyned to the *holy-bone* they produce a neruous originall, ſaith *Fallopius*: a fleſhy, ſaith *Veſalius*, vnder which neruous originall as vnder a certaine ligament or couering lurketh another originall very fleſhy.

From hence aſcending at the outer-ſide they become fleſhy and are inſerted in the tranſuerſe proceſſes of the racke-bones of the loynes: as alſo into all the tranſuerſe proceſſes of the racke-bones of the cheſt, growing by degrees narrower from the eleuenth into the firſt, where they offer one neruous tendon on the inſide like a neruous handle, [Tab. 11, ΜΜ] which is ſpread vpward obliquely toward the outſide, like as the muſcles cal-
Termination. led *Sacro lumbi* did from the out-ſide offer a tendon along all the ribs. Sometime alſo they determine into the firſt *vertebra* of the cheſt: ſometime departing frō the proceſſes they aſcend vnto the mammillary proceſſe of the temple-bone and there end.

A ſinus in thē. On their inſide becauſe of the thickneſſe of the fleſhy part and the tenuity or ſlendernes of the neruous, there is grauen through their length a certaine *Sinus* or boſome, [ta. 29, betwixt φ and ω] to giue way to the third muſcle of the backe which is called *Sacer*.

Their vſe is directly to extend the backe and the loynes if they be contracted together *Columbus* and *Archangelus* thinke that they bend the whole backe & head alſo backward, ſo that our body thereby may be compaſſed into a halfe circle, which kind of Poſture we may ſee in Tumblers when they play their feates. But if one of them onely be contracted, the ſpine is extended on one ſide, for their fibres are oblique.

The third paire are called *Sacri*, or the holy muſcles, [Tab. 29, Ψ] They lye vnder the former.

They ariſe both touching one another, [Tab. 29, ϰ] with an acute originall from the vtter part of the holy-bone where the ſpine is faſtened with the haunch-bones; as alſo frō the trāſuers proceſſes & the roots of the ſpines of the rack-bones of the loines, [ta. 29, ϡ] or if you pleaſe ſay with *Fallop.* that they aſcend frō theſe proceſſes & are increaſt with diuers originals,

originals; as also from the racks of the chest, and that with a threefold originall, one higher from the end of each transuerse processe, another lower, as it were from the roote of the same processe, the third from the spines of each racke bone: so that they seeme to bee three kinds of muscles mixed together; one outward hauing long fibres, another inward hauing short, a third hauing yet shorter, which ariseth from the spines. After their originall they grow brode by degrees, but before their termination which is acute and made into the spine of the twelfth, sometimes of the eleuenth sponder of the chest, they become slenderer. Their fibres run obliquely vpward and inward. Their vse is, if they worke together and contract their fibres to extend that part of the spine to which they are fastened. But if one of them alone worke, it extendeth a part of the backe obliquely, and putteth the body on the one side into a semicircular forme. Termination and vse.

The fourth paire are called *Semispinati*, [Tab. 10. 11. 29. 25. 9.] they arise with an acute originall from the spine of the twelfth rackebone, sometimes of the eleuenth of the chest; and arising vpward by degrees they grow thicke and fleshy, especially at the spine of the fifth racke of the chest being interexed or wouen with neruous fibres: they imbrace all the spines of the rackes of the same. Presently after they become attenuated and doe determine with an acute end into the spine of the first rackebone of the chest. Their fibres are most what right. These muscles as also the former paire do fill vp the distances betwixt the spines, where they are contigual, that is, touch one another. And nothing beside a membranous ligament issuing from the vppor spine into the lower commeth betweene them. Originall. Termination Fibres.

Their vse is to gather together the spines wherein to they are inserted, and to extend or lift vp that part of the backe to which they grow; or the backe properly called *Dorsum*, together with other muscles the loynes being vnmoued. When one of them onely worketh it mooueth the backe to the side; but when all eight muscles conspire together, the whole backe is bowed directly downeward. If foure worke together so as one follow another, they mooue it into a semicircle: but if the muscles that be on the one side do work alone, the body is inclined to that side. And thus much of the muscles of the backe. Their vse.

CHAP. XXXVI. *Of the muscles of the Fundament, the Bladder, the Testicles and the Yard.*

BEcause Man was a politique creature, made for Action and contemplation, it was not fit that he should either receiue his nourishment, or auoyde his excrements perpetually as plants doe, but at his owne choyce. As therefore in the Chops there are muscles seruing for diglutition or swallowing, so in the end of the guts and the outlet of the vrine, there are muscles set as porters to interclude the passage vnlesse we list to open it.

The muscles therfore of the Fundament are foure, two *Sphincters*, and two *Leuators*; one of the spincters is fleshy [ta. 30. fig. 1. ᵃ·] arising from the lower racks of the holy bone, and like a ring is so implicated with transuerse fibres to the extremity of the right gut, that it altogether shutteth the fundament. The other spincter is fleshy, and in my iudgment, saith *Laurentius*, seemes to be nothing else but hardened skinne wouen with fleshy fibres, therein following *Galen* in the thirtieth chapter of his booke *de dissectione musculorum*: *Falopius* also is of the same mind, yet *Bauhine* maketh but one muscle of these two, which saith he, is tyed on the backe side to the rumpe bone, on the foreside with fibrous tyes to the outlet of the bladder and to the yard, to whose muscles it affordeth an original as also to the necke of the wombe. At the sides it is tyed with round ligaments produced out of the holy bone vnto the haunch bone, and is strangely commixed with the insertions of the *leuators*. The spincters

The two leuators [tab. 30. fig. 1. ᵇ·ᶜ·] doe lie vnder the bladder, they are small muscles, but neruous and broade arising from the ligaments of the share, haunch and holy bones, thence descending they reach vnto each side of the *seate* where they compasse the gut, & Two leuators.

[*Table*; 9. *Is the same with Tab.* 12. *in the* 3. *Booke fol.* 126.]

are inserted into the vtter coate thereof, and the vpper part of the spincter, [tab. 30. fig. 1. E.] a portion of them also groweth to the roote [tab. 30. fig. 1. D.] of the yard, and the necke of the wombe. VVhence it is that some haue made them three muscles.

Their vse is after excretion to retract the fundament, and if these muscles be weake or resolued, then followeth that disease which they cal *Aniprocidentiam*, or the falling of the fundament. Their vse

The

Of the bladder. The bladder alſo hath a ſphincter muſcle ſeated in the beginning of his necke, from which it cannot be diſtinguiſhed, and indeede it is nothing elſe but a more fleſhy ſubſtance of the ſayd necke wouen with many tranſuerſe fibres, by which it is conſtringed. If this Muſcle bee either relaxed or refrigerated or wounded, the Vrine followes againſt our willes. In women it is thicker then in men, becauſe there be no proſtate Glandules.

Of the Muſcles of the Yarde we haue ſpoken before in the 8. chapter of the 4. Booke, which it ſhall not neede to repeate. Onely we remember that they are foure, two collaterall, and two called *Inferiores* or the lower Muſcles.

Of the Muſcles alſo of the Teſticles we haue ſpoken before in the 4. chapter of the 4 Booke. Remember onely that they are two and called *Cremaſteres* or the ſuſpending Muſcles. Now we deſcend vnto the Muſcles of the Legge.

CHAP. XXXVII. *Of the Muſcles of the Legge.*

BEcauſe the Muſcles of the Thigh cannot bee demonſtrated before the Muſcles of the Legge are viewed, wee will firſt ſpeake of the Muſcles of the Leg following therein the order of Diſſection. The Legge therefore is that part of the Foote in the large acception, which is betwixt the knee and the foote properly ſo called.

What the leg is.

It conſiſteth like the cubit of two bones: the one beareth the name of the whole and is called *Tibia* the *Legge*; the other is called *Fibula*, we may call it the *Brace-bone*. Now the Legge is moued either by it ſelfe or by accident with three motions, for it is bent or extended directly, and it ſeemeth alſo to be mooued obliquely outward. It is bent by fiue Muſcles, extended by foure, one onely moueth obliquely. By accident the Leg is moued after the Thigh, and that is either to one ſide or about. Firſt we will entreate of the Benders.

His motions And number of his muſcles

The firſt. The firſt Bender or the longeſt [Table 31. and thoſe that follow, fig. 1, 2, 4, 7, 8, *a*] with which we meete on the foreſide preſently vnder the skinne, ariſeth with an acute [fig. 1, 3 7, a] neruous and fleſhy originall from the inner appendix of the haunch-bone, preſently becomming fleſhy it runneth with a decuſſation like a ſlope ſwathe thorough the inſide of the Thigh, being very ſlender and lying vpon the other Muſcles. Neare the bone it is yet narrower [fig. 1, 2, 7, 8, *b*] and endeth in a neruous Tendon, which is inſerted in the fore and inſide of a ſharpe line which is in the bone of the Legge [Tab. 7. c is the inſertion of the firſt ſecond and third muſcles of the Leg].

His vſe is the ſame with the two following, that is, to bend the Legge inward, and withall to lift it vpward.

The 2 muſcle. The ſecond muſcle of the Legge which is alſo called *gracilis* or the ſlender muſcle, [Ta. 31. and thoſe that follow, fig. 1, 2, 4, 5, 7, 9, *c*] is ſituated, eſpecially the belly of it, in reſpect of the former inward and ſo lyeth cloſe vnto it.

It ariſeth with a neruous and large originall [fig. 2. *dd*] at the meeting of the ſhare-bones to which alſo it groweth, and is as big and large as that commiſſure or meering is: Afterward it becommeth narrower but more fleſhy, attaynıng through the inſide of the thigh vnto the knee, determineth into a Tendon exactly round at the inner head of the Thigh, not farre from the knee; where alſo the muſcle becommeth rounde before the Tendon grow from it. VVhen the Tendon is a little dilated it is inſerted into the Leg neare the firſt Muſcle but a little more inward, and it is of the ſame vſe with the former.

The third. The third bending Muſcle which is called *Semi-neruoſus* halfe ſinewy, [Tab. 31. and thoſe that follow, fig. 2, 3, 4, 5, 6, 7] is ſeated on the backſide, and ariſeth from the vpper part of the protuberation of the haunch-bone [fig. 5, 6, *f*] where it is neruous and ſlender, but aboue the middle of the Thigh it becommeth fleſhy and maketh a rounde Muſcle, which deſcendeth a little obliquely by the backſide and inſide of the Thigh, at whoſe inner head it is reflected and attenuated [fig. 5. *e*] and inſerted with a round tendon in a man (in Apes ſometimes it is broade) into the forepart of the Legge, where alſo the two former were inſerted, but the tendon of this third deſcendeth vnto the middle of the Legge.

The fourth. The fourth bender is called *Biceps* or the double headed Muſcle. [Table 31. and thoſe that follow, fig. 1, 3, 4, 5, 6, 10, 13, *g*] It ariſeth with a neruous acute and ſlender original, [fig. 6. *h*] out of the lower part of the haunch-bone or out of his protuberation. Preſently after it becommeth fleſhy, and deſcending through the vtter and backſide of the thigh in the inſide thereof about the middle (where it appeareth neruous) it receiueth a fleſhy

por-

portion [fig.6.k] as it were a new muſcle ariſing out of the middle of the Thigh whereby this muſcle is ſtrengthned, for the outward part there is onely this one muſcle, but on the inſide there are foure. This portion is ſo mixed with the muſcle when it produceth his Tendon, as if another muſcle did there ariſe. [fig.6.k ℓ] Wherefore it may be numbred for one or for two muſcles. A portion increaſing it.

Both theſe deſcending and on the outſide neruous, do end in a notable Tendon which is implanted into the acute proceſſe of the *fibula* or the *Brace*. [fig.10.i] For the behoofe alſo of this Tendon, the head of the Thigh hath a long externall *ſinus* or cauity cruſted ouer with a ſmooth and ſlippery Ligament wherin it is ſecurely conueyed, and beſide, leaſt bending obliquely that way it ſhould go out of his tract.

The fift bender is called *ſemi-membraneus* that is, the halfe membranous Muſcle. [ta 31. and thoſe that follow, fig. 2,3,4,5,6,13, ee] It runneth through the backeſide of the Thigh, and ariſeth with a neruous and acute originall from the appendixe or protuberation [fig.6.m] of the haunch-bone neare the head of the third Muſcle. [figu.6.f] It continueth neruous longer then any Muſcle of the body, but at the middle of the Thigh it beginneth to be fleſhy, and in his lower part thick, and neare the knee endeth into a round Tendon, [figu.6.] wherewith a little dilated it is inſerted into the inner ſide of the Legge, with the firſt ſecond and third Muſcles. The fift,

This Muſcle alſo being very liuid in the backpart beyond the middeſt hath a boſome or cauity in it, [fig.6.n] VVhereuppon the forepart of the third Muſcle leaneth, and in his whole courſe applyeth it ſelfe thereto, ſo that they appeare to be but one muſcle.

The ſixt Muſcle of the Legge or the firſt extender which is called the *membranous-Muſcle*, [Ta. 31. and thoſe that follow fig, 1,2,4,7,8,r] occupyeth the outward and middle part of the Thigh, & ariſeth [fig,1,4,7,p] fleſhy and ſharpe from the Spine of the haunch-bone: and being conuayed to the ioynte of the hip (at which place onely it is fleſhy) and becomming narrower it departeth neare the outſide of the greater proceſſe of the thigh, into a very long and broad [fig.7.*] membrane of the nature of a tendon, then which ther is no greater in the whole body, for like a skinne or a tranſuerſe Ligament it compaſſeth almoſt all the Muſcles of the Thigh (but it is not in all places alike thicke) and holdeth them in their proper ſeates (as we ſaid before the Muſcles in the cubit were inueſted) and incloſeth alſo the ioynt of the knee. The ſixt or the firſt extender.

This Tendon at his inſertion is mixed with the Tendons of the following Muſcles, and is infixed into the forepart and vtter ſide of the Legge. His vſe is to extend it directly and to moue ſtraight forward.

The ſeauenth or the ſecond Extender, which is alſo becauſe of his greatneſſe called *Vaſtus externus*, *The Vaſt Externall Muſcle*, is wholly liuid [Ta. 31. and thoſe that follow fig 1,3,4,5,6,8,9,10,12,H] and occupieth the outſide of the Thigh, as alſo a great part of the foreſide and the backeſide. The ſeauenth

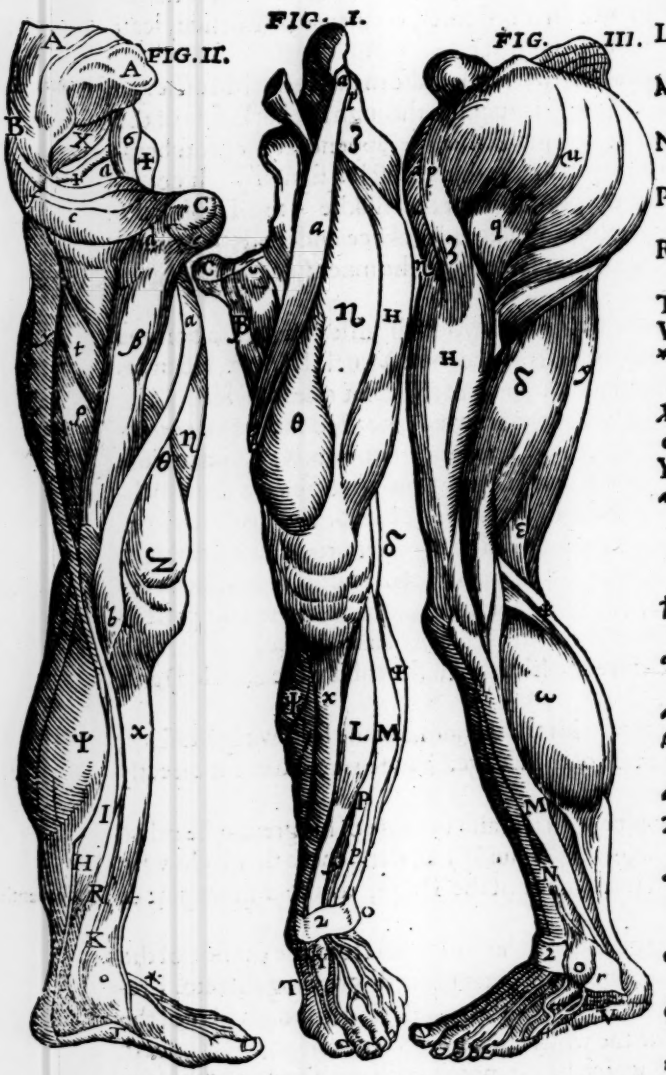
It ariſeth [fig.9.s] with a broade large and neruous originall from the outſide of the Thigh, and compaſſeth round about the root of his great proceſſe growing thereto. Preſently after the originall it becommeth thicke and fleſhy, and lying vppon a part of the eight, it is wholly fleſhy, and a little aboue the whirle bone of the knee [figu.9.x] it endeth into a large and membranous Tendon, which being mixed with the Tendon of the two following muſcles, deſcendeth at the outward ſide of the ſame whirle bone which it doth encompaſſe: and is inſerted [fig,9,u] into the foreſide of the Leg immediately vnder the ioynt.

The eight or the third Extender which is called *Vaſtus internus*, *The Internall Vaſt-Muſcle*, [Ta,31, and thoſe that follow, fig,1,2,4,5,6,7,8,10,11,12,13,14,θ] compaſſeth on the inſide almoſt all the circumference of the Thigh-bone. The eight.

It ariſeth fleſhy from the necke [figu,10,y] of the Thigh, and preſently becomming fleſhy, a portion of it groweth out of the roote of his great proceſſe as if it had a double originall. This latter originall, if you liſt ſo to call it, deſcendeth large and oblique, and becomming by degrees more fleſhy it buncheth or beareth out at the inſide of the Thigh neare the whirle-bone into a thicke and fleſhy ſemicircle, out of which groweth a ſtrong Tendon which occupyeth the whirle-bone alſo. [fig,9,u] This portion ſome doe make a diſtinct muſcle and call it *Crureum*. [figu,2,7,8,9,Z] This Muſcle with the former maketh a *ſinus* or boſome very liuid, [fig,9,char.1] that the ſubſequent muſcle might lye vpon it throughout his length.

Table 31 With thoſe that follow, ſhew the ſixe muſcles of the Legge, the Thigh, and of the foote. Fig. 1. ſheweth the fore and muſculous part of the left Thigh. Fig. 2. ſheweth the internall and laterall part of it. And fig. 3. ſheweth the externall laterall part of it.

TABVLA XXXI.



A A, The holy-bone.
B 2, A ligament drawne from the holy-bone vnto the hip.
G 1,2, the ſeate of the holy-bone.
H 2, the third muſcle extending the ſoale called *Plantaris*.
I 1, the fourth muſcle extending the foot or the ſoale muſcle.
K 2, the fift muſcle extending the foote, called *Tibiæus Poſticus*.
L 1, the firſt muſcle bending the foot called *Tibæus anticus*.
M 1,3, the ſecond bender of the foote called *Peronæus primus*.
N 3, the third bender of the foote called *Peronæus ſecundus*.
P 1,3, the ſecond extender of the toes, or the ſtretchers.
R, the ſecond bender of the toes, or the great bender.
T 1 2, the lower abductor of the great toe
V 3, the abductor of the little toe,
* 2, Tendons carried vnto the toes of the foote.
X 2, the internall part of the fourth muſcle of the thigh as it were three-fold, at *a, c, f*.
Y 1, the vpper abductor of the toes.
acf, A part of the tenth muſcle of the thigh as it were three-fold at *a c f*, and carried vnto the great proceſſe of the thigh.
† 2, A great nerue lying vppon the tenth muſcle betweene *x* and *a*.
α 1,2. the muſcle of the leg, or the firſt bender which is the longeſt muſcle.
a 1,3, His originall. *b* 1 2. His tendon.
β 1 2, the muſcle of the leg or the ſecond bender which is the ſlender muſcle.
de 2, His originall. *d* His tendon.
γ 2,3, the third muſcle bending the tibia called *Seminerueſus*.
δ 1,3, the fourth muſcle bending the leg, called *Biceps* or the double headed muſcle.
εε 2,3, the fift muſcle bending the legge called *Semimembraneus*.
ζ 1,2, the firſt muſcle extending the legge called *membranoſus*.
η 1,3. the ſecond muſcle extending the leg called *Vaſtus externus*. *θ* 1 2, the third muſcle extending the leg called *Vaſtus internus*. *κ* 1,2,3, the fourth extender of the leg, or the *Right* muſcle. *μ* 3, the firſt extender of the thigh, called *Glutteus maior*. *ο* 2. the inner anckle. *o* 1,3, the vtter anckle, *ρ* 1, A fleſhy part of the firſt extender of the leg, *ϱ* 2, the fift extender of the thigh called *Triceps* or the three headed muſcle. *σ* 2, the firſt bender of the thigh called *Lumbalis*. *τ* 2, the ſecond bender of the thigh called *Illiacus*. *υ* 1, the third bender of the thigh. *ϕ* 1,2, the firſt extender of the foote, or the internall *Gaſtrocnimius*. *ω* 1,2,3, the third extender of the foote, or the external *Gaſtrocnimius*. *p* 1, A portion of the ſecond extender of the toes, which *Veſalius* maketh the ninth muſcle of the foote. *q* 3, the greater proceſſe of the thigh called *Rotator*. *r* 3. the tranſuerſe ligament reaching from the brace to the heele. *t* 2, A portion of the 5. muſcle of the thigh. *x* 2, the bone of the legge bare. *y* 1,3, the tendon of the firſt extender of the toes. *z* 1 3, A tranſuerſe ligament aboue the foote.

The ninth or the fourth extender called alſo the right muſcle, [Tab. 31, and thoſe that follow fig. 1,2,3,4,5,7,8,9,*] lyeth on the outſide vppon the firſt bender, and is ſeated on the middeſt of the forepart.

It ariſeth with a neruous and acute originall [figure 8, character 1] from the internall protuberation of the haunch bone on the fore-ſide aboue the Cuppe of the Coxendix.

From

From thence it is deriued directly through the length and forepart of the thigh betweene the ſeuenth and the eight muſcles, and being by degrees increaſed with a fleſhly ſubſtance it becommeth againe by degrees more ſlender aboue the middle of the thigh, [fig. 8. char. 2.] and determineth into a very long and exceeding ſtrong tendon aboue the whirle, where it is a little narrower and more ſlender.

But in the forepart of the whirle it is againe dilated, and being mixed with the tendons of the two forenamed muſcles is very ſtrongly inſerted to the leg on the foreſide immediatly vnder the ioynt. But in Munkies it is moſt what membranous and inſerted into the leg much lower. Neither this onely, but alſo the tendons of the other muſcles are more membranous and broder in men then in Apes. And with this tendon of the three muſcles is the whirle bone couered, yea it groweth to his forepart, and ſerueth the knee for a ligament. Munkies.

This is the muſcle which is like a Snake or the fiſh (becauſe of his broade tayle) which is called *Mus* or the *Mouſe*, which vſhereth the Whall that he offend not againſt the rockes, from which fiſh the muſcles of the whole body haue their denomination.

The tenth and laſt muſcle of the leg is called the *oblique mouer*, and from his ſituation *poplitæus* the muſcle of the Ham, [tab. 34. 38. fig. 14. 16. 28. AA.] for it lurkes in the ham vnder that muſcle of the foote which is called *Gaſtrocnimius*, and *Plataris* next of al to the bones, and therefore we canot meete with it before theſe bee remoued. It is a ſhort and ſlender muſcle and iſſueth with a neruous [fig. 16. char. .] and round originall from the externall head of the thigh, after it is increaſed with fleſhy fibres and running vnder the ligament, climing obliquely ouer the bone *Tibia* or the leg, determineth brode and fleſhy and is inſerted into the backe and inner part of the legge at his appendix. [Tab. 31. char. 5. The tenth.

His vſe is to moue the leg obliquely outward, and therewith alſo to turne the foote ſomewhat inward toward the other, for the foote is ſpecially articulated with the leg-bone, and therefore *Galen* ſayd that it was the principall author of the bending of the leg.

CHAP. XXXVIII. *Of the muſcles of the Thigh.*

THE Thigh is that part which is betwixt the ioynt of the huckle bone and the knee, and conſiſteth of one bone as doth the arme. This part becauſe it is moued according to our good pleaſure by reaſon of his round head, and that with all kind of motion, it ſtood in neede to haue muſcles and thoſe very many.

Theſe muſcles doe moue the thigh either directly or in compaſſe. Directly, either lengthwiſe or ouerthwart, and that either by extention or by flexion. It is extended either when we ſtand vpright and make (as we ſay) a curteſie, bending the thigh moderately inward and downeward toward the earth. Or backeward into the poſterior part when wee lift our thighs vpward, eſpecially toward the outſide; which kinde of poſition may bee ſeene in that they call a *Backe caper*. This extention is made by the helpe of fiue muſcles, which moſt what doe occupie the poſterior part. And the firſt foure of theſe doe lie vpon the huckle bone, and the fifth vpon the thigh. The motions of the thigh.

The thigh is bent when we lift it vpward and forward, and eſpecially toward the inſide; (in extenſion it is toward the outſide) as it is in Anticke dances, and this motion is performed by three muſcles ſituated before; two of them are ſeated in the cauity of the belly, and the third in the thigh. 11. muſcles of the thigh.

The circumaction or compaſsing of the thigh is either inward or outward, and performed by three muſcles placed in the coxendix. VVee conclude therefore that there are eleuen muſcles of the thigh, although I know many more may be named if we diuide the fifth muſcle into foure; make two of the fleſhy pouch which compaſſeth the tendon of the tenth muſcle, & adde the twelfth muſcle deſcribed by *Arantius*: for then each thigh ſhall haue ſeuenteen muſcles which ſhall extend it, bend it, leade it in compas, draw one thigh two another, diuide them aſunder, or lift one thigh ouer another, as Taylers vſe to ſit at their worke. Of all which motions we will ſpeak in order.

The firſt extender is called *Glutæus maior* the greater *buttocke muſcle*, becauſe it maketh almoſt all the buttocke on one ſide; [tab. 31. and thoſe that follow fig. 3. 4. 8. μ.] for it is thicke and fleſhy and lyeth iuſt vnder the skin, being appointed with the two following to make the quiſhion of the ſeate.

It ariſeth with a fleſhy broade and ſemi-circular originall, from the whole circumference of the haunch bones, from the lower part of the holy bone where it is contiguous with his oppoſite, and from the beginning of the rumpe bone. [tab. 32. fig. 4. a b c.] Afterward deſcending a little obliquely and riding ouer the ioynt of the huckle-bone which it ſtrengthneth, as it were, with a couering it becommeth narrower and more ſlender, and ſo endeth into a ſtrong and brode tendon, which is partly inſerted into the roote of the greater proceſſe, partly below it into the outſide of the thigh bone, and that obliquely.

The vſe of this muſcle is when it worketh all together to ſettle the backeward and

ε 6, the hinder part of this muſcle.

χ 5, 6, the firſt circumactor or the muſcle leading the thigh about called *Obturator internus*, together with fleſhy portions both aboue and below, and growing vnto it.

ϟ 4, the firſt extender of the foote called *Gaſtrocnimius internus.*

ω 4, the ſecond extender of the foote called *Gaſtrocnimius externus.*

a b c, 4, the originall of the firſt extender of the thigh.

d e, His inſertion.

f g, 5, 6, the originall of the third bender of the leg called *Seminerueſus* at *f*, the beginning of his tendon at *g*. i k, 5, the ſemicircular originall of the ſecond extender of the thigh at *b*, His inſertion into a proceſſe of the thigh. *b* 6, the head of the muſcle called *Biceps*, or the fourth bender of the leg. *k* 6, A fleſhy portion whereby it is increaſed. H 4, the fourth extender of the foote called *Plantaris.* l 5, A portion of the fift muſcle extending the leg, or of the muſcle called *Semimēbraneus.* m n o 6, His head *m*. The beginning of his tendon *o*. A boſome or cauity in which the third extender of the leg doth reſt, *n*. r 4, A fleſhy part of the extender of the leg, called *membranoſus* at *p* His originall. *p* 6, the backe of the haunch-bone bare. *ſ x* 6, the circumſcription of the third bender of the thigh, *ſ* 6, the inſertion of the third and fourth extenders of the thigh, *t* 5, 6, the great and vtter proceſſe of the thigh. *u* 5, 6. A ligament going from the holy-bone into the acute proceſſe of the hip, x 5, A ligament going from the holy-bone into the back-part of the hip. *y* 5, the fourth nerue which is the greateſt nerue of the whole legge, wherein is the tumor collected which cauſeth the hipgowte. * A ſinus or cauity wherein the great veyne of the legge and the artery together, with the nerue are conueyed. 12. char. 6, the fourth nerue parted into two in the ham, the greater branch 1, the leſſer 2. 34. charact. 6, the membranous beginning of the oblique aſcendent muſcle of the *Abdomen* from the ſpine of the backe. 8, 9, charact. 6, Two fleſhy portions, or the *fleſhy ponch*, and heauing to the ſecond *Circumactor*, or compaſsing muſcle of the thigh.

to

to extend it directly; for if but one part of the muſcle bee contracted, then the motion is not equall but more outward to this or that ſide.

The ſecond extender which is called *glutæus medius*, the middle buttocke muſcle [tab. 32. and thoſe that follow fig. 4. 5. 8. 9. ν.] lyeth for the moſt part vnder the firſt. The reſt of it is couered with a membrane. It is alſo like the firſt in forme, but leſſe and very liuide, as alſo is the third in leane bodyes, but in thoſe that are fat eſpecially in women we often find neruous fibres running through them to which fat groweth, to make the ſeate the ſofter. The ſecond.

It ariſeth with a fleſhy, broad and ſemicircular originall, [Tab. 32, fig. 5, *hi*,] (a little lower then the firſt to whoſe originall it giueth way) from the rib of the haunch-bone on the fore-part and from the backe of the ſame haunch, and indeede it occupieth almoſt all the circumference of that bone: thence deſcending obliquely it groweth narrower by degrees, runneth vnder the forward muſcle, couereth the ioynt of the hippe, and determineth into a broade, ſtrong, and membranous tendon, [fig. 5. k.] which is implanted into the fore and vpper part of the great *Trochanter* or proceſſe of the necke of the thigh, which it compaſſeth on euery ſide but ouerthwart.

His vſe is to extend the thigh and to draw it vpward and forward into one ſide, and that more manifeſtly then the former muſcle. The fibres alſo of this muſcle make a decuſſation with the fibres of the former, [Tab. 5, μ with ν.]

The third *Extender* called *Glutæus minor, the leſſer buttocke muſcle* [tab. 32. and thoſe that follow fig. 6. 10. ξ.] lyeth wholy vnder the ſecond, and is ſo much leſſe then it, as the ſecond is leſſe then the firſt. It ariſeth from the backe of the hanch bone, and from his backeward and lower part where the bone of the coxendix beginneth; and his original, (as the two former) is fleſhy, thick, and ſemicircular. [fig. 6. qſ x.] Then declining downward and forward, it cleaueth eaſily with fibrous tyes to the ligament of the ioynt of the hippe and becomming narrower determineth into a brode and ſtrong tendon, which climing ouer the greater *trochanter* or proceſſe of the thigh, is implanted to the very top of his forepart, where it is a little inuerted. [fig. 6. ſ.] The third.

His vſe is to drawe the thigh moderately vpward and backeward, and ſo to extend it.

The fourth extender called *Iliacus externus pyriformis, the outward hanch peare muſcle* [tab. 32. fig. 5. 6. and tab. 34. fig. 13. π.] becauſe it filleth the outward and lower cauity of the hanchbone with his oblique poſition, and is like a round peare. This muſcle is liuide, and ariſeth with a fleſhy and round originall from the three lower rackes of the holy bone, or from the inner part of the ſides, where ſomtimes it is continual with his oppoſite: thence it runneth downeward but fleſhy and ouerthwart to the great *trochanter*, but before it touch the thigh it becommeth narrower and endeth in a round tendon, which is obliquely implanted into the great *trochanter* or head of the thigh on the backeſide neare his appendix. His vſe is to draw the thigh moderately vpward and backeward, and ſo to extend it. It is alſo ſome litle helpe toleade the thigh round but forward, yet more then the third muſcle. The fifth extender is comonly called *Triceps* becauſe it hath a threefold originall, but may better be called *Quadriceps*, for his originall is fourefold. [Tab. 31. and thoſe that follow fig. 2. 4. 6. 8. 9. 10. 11. 12. 13. 14. ſſ.] This is the thickeſt muſcle in the whole body of man, and ſtuffed with a wonderfull variety of fibres, inſomuch that becauſe the parts thereof doe differ among themſelues in their originall, fibres, inſertion, coates, and in ſome ſort in their vſe likewiſe, *Falopius* ſaith, and ſo may we alſo, that there are ſo many muſcles as there are parts of this muſcle, to which alſo the right muſcle which ſeemeth to be a part thereof muſt be referred, whoſe originall is ſeated vnder the three heads of the muſcles which make the bulke of the leg. [Tab. 32. fig. 6. fhm.] But we wil here vnder exhibite his diſcription according to *Falopius*. The fifth. The thickeſt muſcle of the body.

The firſt part [Tab. 35. fig. 12. a part of the muſcle is at ν.] ariſeth with a neruous originall from the vpper line of the ſhare bone, and deſcending is inſerted into a rough line of the thigh vnder the middle. Notwithſtanding from his tendon proceedeth a ſlender portion which is vnited with the tendon of the fourth part and is inſerted into the lower head of the thigh, and the inſide of the knee.

The ſecond part [Tab. 35. and 34. fig. 13. and 14. char. 6.] ariſeth from the lower parts of the commiſſure of the ſhare bones where they ioyne together. It is fleſhy and broade and hath oblique fibres, deſcending alſo downeward, it is implanted into the line of the thigh in the vpper part thereof.

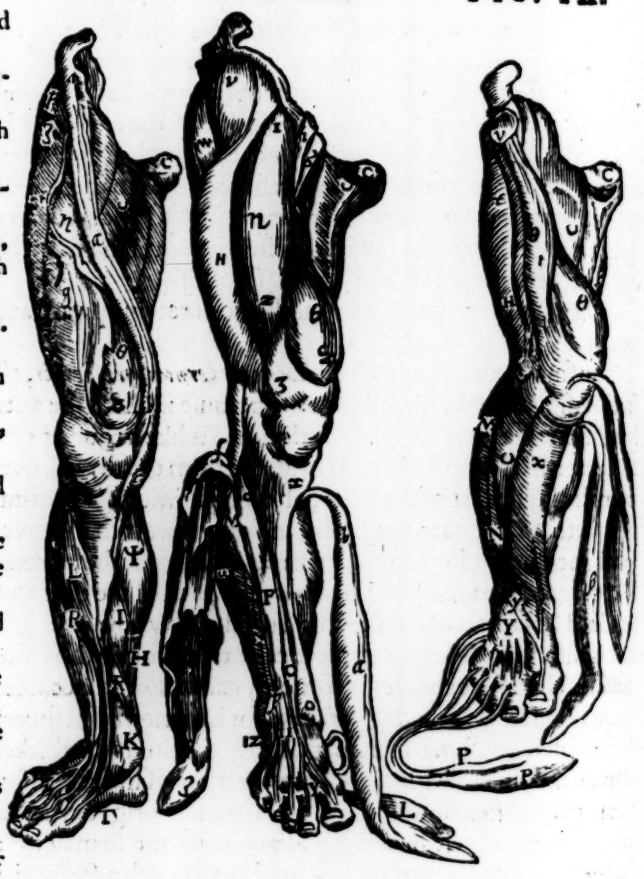
Third part [ta.34.fig.13.char.6.fig.14.char.7.confered fig.13.ρσυ, among themſelues] ariſeth with a fleſhy, ſometimes a neruous originall from the apendix of the *Coxa* yea from the whole coxendix round about the circumference of his brode hole, his fibres are very diuers, ſo that it ſeemeth to be a double muſcle, for the vpper fibres are as it were, tranſuerſe, but many of the lower oblique. This part deſcending is inſerted into a rough line vnder the little *trochanter* or head of the thigh.

The fourth part, [Tab.34.fig.12. and 13.ρuxy, ariſeth with a neruous fig.13.ª.] and then fleſhy [ˣ] originall from the the appendix of the *coxa*, which two originals forme a muſcle whoſe belly is dilated into a ſtrange breadth [fig.13.ρ] afterward running along the backeſide of the thigh, it endeth into a round tendon [fig. 13. vnderᶻ] which with a ſlender portion of the tendon of the firſt part is inſerted into the inner and lower protuberation of the thigh [three parts of this muſcle are demonſtrated, tab.36.12.ρσυ. where they hang downe alſo. Tab.34.fig.14.ρ 6. 7.]

Table 33. ſheweth ſome Muſcles of the Leg and the Foote.

TABVLA. XXXIII.

FIG. VII. FIG. VIII. FIG. IX.



α 7,8. The firſt bending muſcle of the Leg called *Longiſſimus.*

β 7,9, the ſecond bender of the Leg called *Gracilis.*

ζ 7,8, The firſt extender of the Leg called *Membanoſus.*

η 8,9, the ſecond extender of the leg called *Vaſtus externus.*

θ 7,8,9, the 3. extender of the Leg call *Vaſtus internus.*

ι 6, A *ſinus* or cauity vpon which the ninth muſcle of the thigh lyeth.

χ 7,8,9, the fourth extender of the Leg called *Rectus.*

1,2,3.char.8. The originall, 2. The tendon, 2. the place where the tendon groweth to the tendons vnder it.

μ 8, the firſt extending muſcle of the thigh.

ν 8,9, the ſecond extender of the thigh.

ρ 9, A portion of the 3. muſcle of the thigh called *Triceps.*

σ 8, the firſt bender of the thigh called *lumbalis.*

τ 8, The ſecond bender of the thigh called *Iliacus internus.*

1,2,3, char. 8, His original, 1, tendon 2 the place where the tendon groweth to the tendons vnder it.

υ 7,8,9, The third bender of the thigh cald *Glutæus minor.*

ω 8, The ſecond externall extender of the Foote.

b 7,8, the tendon of the firſt muſcle of the Leg neare the knee.

c 7, The inſertions of the 1 2 and 3 muſcles of the Leg.

d 8, the inner ankle.

p q 7, the fleſhy part of the firſt extender of the leg, his large membrane at *q.*

r 7, his originall. ſ 8, his inſertion. *t u x* 9, the beginning of the 2 extender of the Leg. *t.* his inſertion, *u.* his tendon *x.* *y* 8, the tendon of the firſt extender of the toes at the great toe. C 7.8.9. the place of the ſhare-bone. H 7, the third extender of the foote called *plantaris.* I 7, The fourth extender of the foote called *Soleus.* K 8, the fift extender of the foote called *Tibiæus poſticus.* L 7,8, the firſt bender of the foote called *Tibiæus anticus.* M 8.9, the 2 bender of the foote called *Peroneus primus.* N 8,9, the third bender of the foot called *Peroneus ſecundus.* O 8,9 the firſt extender of the toes called *Pollicis tenſor.* P 7,8,9. the 2. extender of the toes. ρ 8,9. A portion of that muſcle which *Veſalius* maketh ths 9. muſcle of the foot. 10, 11 12: char. 8. the originall thereof 10, his diuiſion into tendors 11, the inſertion of the 9 muſcle 12. R 9. the 2 bender of the toes called *Flexor magnus.* T 7: the lower abducter of the great toe. X 8: 9: the bone of the leg bare. Y 8,9, the vpper abducter of the toes. Z 7,8: the muſcle called *Crureus.* † 7. the firſt extender of the foote called *Gaſtrocnimins internus.*

The

The vſe of this Muſcle although it be to liftvp the Thigh and leade it to the body: yet according to the diuerſity of his partes it hath diuers particular offices: for the backeparte which hath right fibres, eſtabliſheth the thigh and faſtneth it vppon the ground being extended, as when a man ſettes his foote to paſe forward. The backe portion alſo of the anterior part performeth the ſame; but it leadeth the thigh moderately inward as it were to the other thigh, ſo the firſt part of the anterior leadeth the thigh inward and croſſeth one thigh ouer another. And thus much concerning the extending Muſcles, which primarily extend the thigh, and theſe alſo doe helpe it when it is moued ſidelong or ledde about. The vſe of the 5. muſcle.

The Bending Muſcles are three: The firſt is called *Lumbalis* [Table 31. and thoſe that follow fig. 2,8,10,11,12,14,16, char. 6] the Muſcle of the Loynes which *Hippocrates* and *Galen* called ψόας. They are placed a little obliquely in the cauity of the *Abdomen*, and when the entrals are taken forth they preſently appeare in the Loines. It is a roũd, fleſhy, thicke and ſtrong Muſcle, and altogether liuid. The firſt bending muſcle.

It ariſeth fleſhy [Ta. 35. fig, 12. a] from the two lower racks of the cheſt, and the three vpper of the loynes: preſently after it climbeth ouer the reſt of the rackes of the Loynes, and deſcending fleſhy by the haunch-bone [from a to b] it runneth a little obliquely and ſomething outward aboue the ſhare-bone, and ſo determineth into a ſtrong and round Tendon which is inſerted on the foreſide at the vpper part of the leſſer head of the thigh. His vſe is ſtrongly to drawe the Thigh vpward and to bend it inward. And becauſe the tendon of this Muſcle ſhould be ſecurely conuayed, not hurt by the hardnes of the bone, nor yet erre or wander out of his way, there is a *ſinus* or cauity inſculped in the ſharebone which is couered ouer with a membranous, ſmooth and ſlippery Ligament ariſing out of the bone. And becauſe the kidneis lie vpon this muſcle ouer which a notable nerue is diſſeminated. Hence it commeth to paſſe that thoſe that are troubled with the ſtone in the Kidneyes doe find a *ſtupor* or ſleepineſſe on the Thigh on that ſide the ſtone is on.

The ſecond Bender is called *Iliacus internus* the inward haunch-Muſcle. [Ta. 31. fig 2. ↓ Ta, 33. fig. 10,11,12,16, r] At the lower part it toucheth the former Muſcle [tab, 35, fig, 11,12, r as farre as σ] and occupyeth all the inner cauity of the haunch-bone. From thence as it were out of a ſemicircle it ariſeth fleſhy and broade and by degrees becommeth narrower and thicker, and deſending forward aboue the vpper part of the *Coxendix*: it is implanted with a round tendon [Ta, 34, fig, 14 c T] into the leſſer head of the thigh like as the former but ſomewhat lower then the firſt bender. The 2 Bender.

His vſe is together with the firſt Bender to lift the Thigh vpward and ſo to bend it, but this Muſcle mooueth it leſſe inward. And whereas it is carried aboue the *Coxendix*, the bone hath in it a ſmooth and ſlippery cauity for the better conuaying thereof, which cauity where the muſcle bendeth it is liuid, neruous and ſtrong, the better to defend it ſelfe againſt the hardnes of the bone.

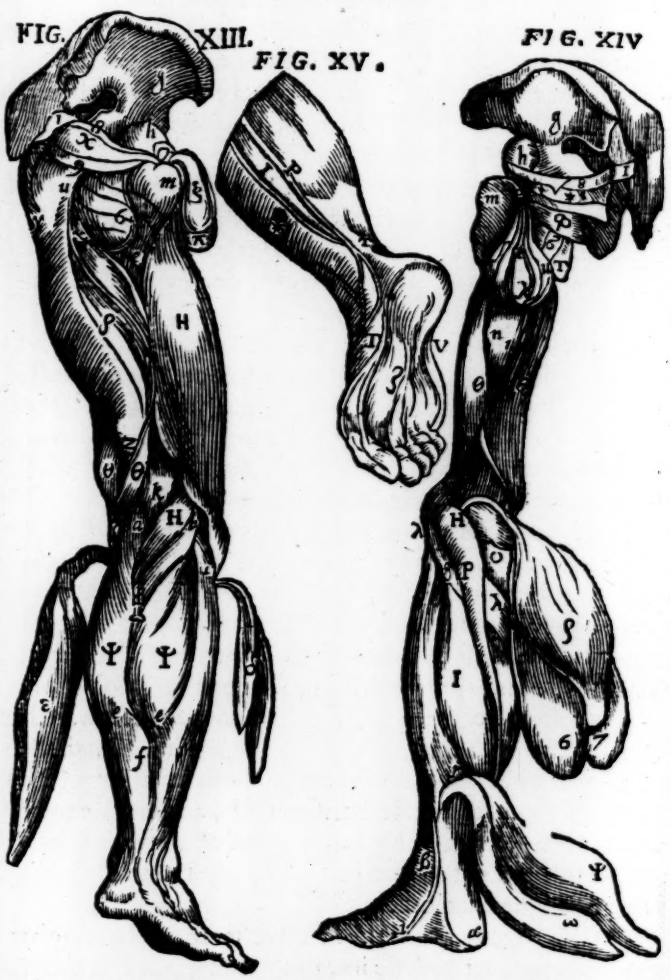
The third Bender [Tab. 31. and thoſe that follow, fig, 1,7,10, 11, 12 υ] is alſo liuid, and ariſeth broade and fleſhy from the Line of the ſhare-bone, hard at his griſtle and runneth obliquely within the fift extender, ſo that ſome haue accoũted it for a fift part of the ſame fift muſcle, and ſo determineth into a ſhort, broade and large tendon which is inſerted at the inſide of the Thigh ouer againſt the leſſer heade and runneth out vnto the backeſide. His vſe is to leade the thigh vpward and inward very ſtrongly and ſo to croſſe one Thigh ouer another. And ſo much for the benders of the Thigh. The 3. bender.

The firſt compaſſer which is called *Obturator externus* the outward filler [Tab, 35. fig. 12,14,16, φ] lyeth vnder the former & filleth vp on the outſide all the hole which is before in the ſhare and the haunch-bones. The forme of it is like a Peare as was the fourth extender. It ariſeth fleſhy and broade from the circumference of the foreſaid hole, and on the foreſide is liuid. It runneth ouerthwart and behinde by the hip ioynt away and the necke of the thigh, is by degrees anguſtated and determineth into a ſtrong and large tendon, which is implanted into a cauity of the great trochander or the head of the thigh. His vſe is to turne the thigh inward, *Laurentius* ſayth outward. The firſt compaſſer.

The ſecond compaſſer *Obturator internus* the inward filler [Ta, 31, and thoſe that follow, fig. 2, [illegible] fig, 5, 6, aboue char, 9 f. 13, 14, χ] lurketh in the bowle of the hanch-bone, occupyeth the inſide of the forenamed perforation, is ſtronger then the former, and diſtinguiſheth therefrom by a Membrane to which it groweth. It ariſeth fleſhy & broad from the circumference of the perforation on the inſide and appeareth notably liuid hauing The 2. compaſſer.

Tab.14. Sheweth the muſcles of the thigh and of the foote.

TABVLA XXXIV.



α 14, A tendon made of three muſcles of the foot & inſerted into the heele
β 14, The beginning of the tendon of the firſt *Peronæus* out of the middle of his body.
γ 14 The tendon of the ſecond *Peronæus* reflected to the outward ankle.
δ 13, The fourth bending muſcle of the leg called *biceps*, hanging downe.
ε 13, The fifth bender of the leg called ſemimembraneus hanging downe.
ζ 15, A ligament in the ſole of the foot ſeruing in ſtead of the brode tendon.
η 13, The ſecond extender of the legge called *vaſtus externus*.
θ 13,14. The third extender of the leg called *vaſtus internus*.
ι 13.14. An acute ligament going from the holy bone into the proceſſe of the hip bone,
κ 14, The muſcle called *poplitæus* mouing the leg obliquely.
ξ 13. A portion of the third muſcle extending the thigh.
ο 13, The fourth extender of the thigh or a portion of the Illiack muſcle.
π 13,14, the fifth extender of the thigh called *triceps*.
ρ 13. Another part of the fifth muſcle.
σ 13, the firſt bender of the thigh called *Lumbalis*.
τ, The 2 bender of the thigh or a tendon of the internall Illiacke muſcle.
υ 14, the firſt compaſſer of the thigh called *obturator externus*.
χ 13,14, the ſecond compaſſer of the thigh called *obturator internus*.
ψ 13,14, the ſecond extender of the foot called *Gaſtrocnimius externus*.
a b, 13, the beginning of the two extenders of the feete. c c 13, their fleſhy beginning. d 13, Their contiguity or meeting together. e e 13, the ſwelling of both the calues. f 13, The beginning of the tendon of theſe muſcles. g 13,14, The backe of the ſhare bone without fleſh, h 13,14, The head of the thigh bone compaſſed and defended with a membranous ligament, k 13, The place of the thigh bone without fleſh. l 14, The rumpe bone without fleſh m 13,14, The exteriot and great proceſſe of the thigh. n 14, A rough line of the thigh whereinto is inſerted the fifth muſcle of the thigh called *triceps*. o 14, The bone of the legge and the outward head of the thigh bored. p 14, The tendon of the third extender of the foote. q 14, The beginning of the fourth extender of the foote, r 14, The inſertion of the tendon of the firſt and ſecond muſcles of the foote. ſ t u, The tendons of the tenth muſcles of the thigh reflected to the hanch bone. u 13. The neruous head of the backe part of the fifth extender of the thigh. x 13, The fleſhy head of the ſame muſcle. y 13. Carrying the proportion of a mouſe. z 13, the tendon of the firſt part inſerted into the inner tendon of the thigh. 6. Char. 13. the third part of the fifth muſcle. 7. Cha. 14. another part of the fifth muſcle. 8 9. Char. 13. two fleſhy portions or the fleſhy pouch which adheereth to the ſecond compaſſer of the thigh. H, 13, 14, the third extender of the foote called *Plantaris*. I 14,15, the fourth extender of the foote called *Solæus* † 15, a cauity betwixt the tendon of the forenamed muſcle & the other. * 15, the place of the bone of the leg without the fleſh, T 15, the lower abductor of the great toe. V 15, the abductor of the little toe

hauing three lines, or inſcriptions. Afterward it is by degrees contracted or ſtraightned, [tab.31.fig.2.[a] c vnto [f]] and runneth ouerthwart aboue the coxendix outward [tab.34. fig.13.[x]] and aboue the ?cauity which is formed like a pully, it haſteneth to the great trochanter where it is reflected: the reflected part being fleſhy, and that which toucheth the cauity neruous. At which cauity it is increaſed with three round tendons [Tab.34.fig. 14.[f.h]] in the very reflection, which tendons beeing a little ſeparated one from the other doe paſſe forward, and when they are paſt the cauity on the backe ſide they are againe collected and make one neruous tendon [tab.43.fig.13.X.8.9.] which tendon is led ouerthwart

thwart and together with the firſt compaſſer is inſerted into the hinder cauity or ſinus of great *Trochanter* or head of the thigh, and into his roote. And this was Natures counſell determining to adde ſtrength to this muſcle; for if it had bene wholy fleſhy in his reflection and motion it would haue beene hurt by the hardnes of the bone. Wherefore alſo there groweth to the Sinus a ſtrong membranous ligament which is ſmooth and lined ouer with a viſcide humor for the more eaſie circumaction of the muſcle. But this Sinus hath appearing in it two lines lightly eleuated, which running ouerthwart doe diuide the three forenamed tendons into three cauities; ſo that in this one cauity euery tẽdon hath a peculiar Sinus.

And leaſt theſe tendons ſhould ſlip out of the cauity of the bone after they are reflected, Nature created a fleſhy purſſe wherein the tendon of this muſcle is placed, which purſſe reſembleth two muſcles, [Tab.38, fig.16.**] one vpper and another lower. The vpper [Ta.32, fig.6, char.8. as alſo the lower [ta.31, fig.6, 13, 14, char.9, fig. 16,*] do ariſe fleſhy and ſlender, from the acute proceſſe of the haunch-bone the vpper, the lower from his appendix & both of them do accompany the ſecond compaſſer euen to his inſertion and are together inſerted into the cauity of the great *Trochanter*.

The purſſe.

like two muſcles.

Their vſe is together with the ſecond compaſſer to helpe the circumaction or compaſſing of the thigh.

Their vſe.

There is alſo another muſcle firſt deſcribed by *Fallopius*, which lyeth vnder the foreſayde purſſe, [Tab.34, fig.14,*] which ariſeth ſhort and very fleſhy from the backe-part of the coxendix and being led about to the outſide of the thigh, is with a ſtrong and roũd tendon inſerted into the backſide of the great *Trochanter*, or into that ſpace which is betwixt the two *Trochanters* or heads of the thigh.

Fallopius his 11. muſcle.

His vſe is to lead the thigh in compaſſe backeward. And this muſcle haply may be diuided into two.

Arantius after he hath deſcribed this muſcle found out by *Fallopius*, he addeth another ſo making the number of the muſcles of the thigh to be a full Iury in theſe words.

Arantius his 12. muſcle.

When you haue cut away the muſcles which bend the legge from their originals, if you diligently marke the place, you ſhal finde vnder the eleuenth muſcle a twelfth, which is much ſtronger then the former, but lyeth very deepe. It hath an originall oppoſite vnto the eleuenth, beginning from the forepart of the ſhare-bone where it is perforated & it is diſtinguiſhed with a membrane of the nature of a Ligament. This originall ſayeth hee, is fleſhy and almoſt orbiculer or round. It degenerateth into a ſtrong and round tendon.

This muſcle being ledde about like a ſemicircle to the outſide of the thigh, together with the ſecond compaſſer and the purſſe, that is, with the tenth and eleuenth muſcles to guide the ſphericall or round motion of the thigh.

CHAP. XXXIX. *Of the Muſcles of the foote.*

THE Foote is moued two wayes directly and to the ſides; directly alſo or in length two wayes: for it is eyther extended backward when it is led out of his tranſuerſe poſition, a little obliquely toward the earth (and that by the helpe of fiue muſcles placed in the back part, together with the ſecond and third benders of the toes) as when we walke or dance: or it is bent forwarde by three muſcles to which may be added that portion of the muſcle which ſome make the ninth, but we account it for a part of the ſecond muſcle which ſtretcheth the toes: and theſe are placed together with the firſt and ſecond extenders of the toes on the foreparte, but the outward ſide of the legge, for the inſide of the legge euen vnto the calfe is without fleſh. This motion is not ſo ſtrong as the former, and therefore doth not ſtand in need of ſo great muſcles.

The motions of the foote.

The foote is alſo moued to the ſides, and ſo a little compaſſed, which motion becauſe it is very weake, hath not any particular or priuate muſcles allotted thereto, but is ledde to the outſide by the anterior muſcles and to the inſide by the poſterior. The extending muſcles therefore of the foote are fiue, and the benders three.

His muſcles.

The firſt *extender* is called *Gaſtrocnemius internus* [Tab.31, and thoſe that follow fig. 1, 2, 3, 4, 13, 14, ☿] *the internall Calfe-muſcle*, ariſeth from the inner head of the thigh about the knee as it were with a double originall. The one vpper [fig 13, *b*] which is fleſhy and broade: the other lower and vtter which is neruous and liuid. [fig.13, *c*.] The firſt

The firſt extender.

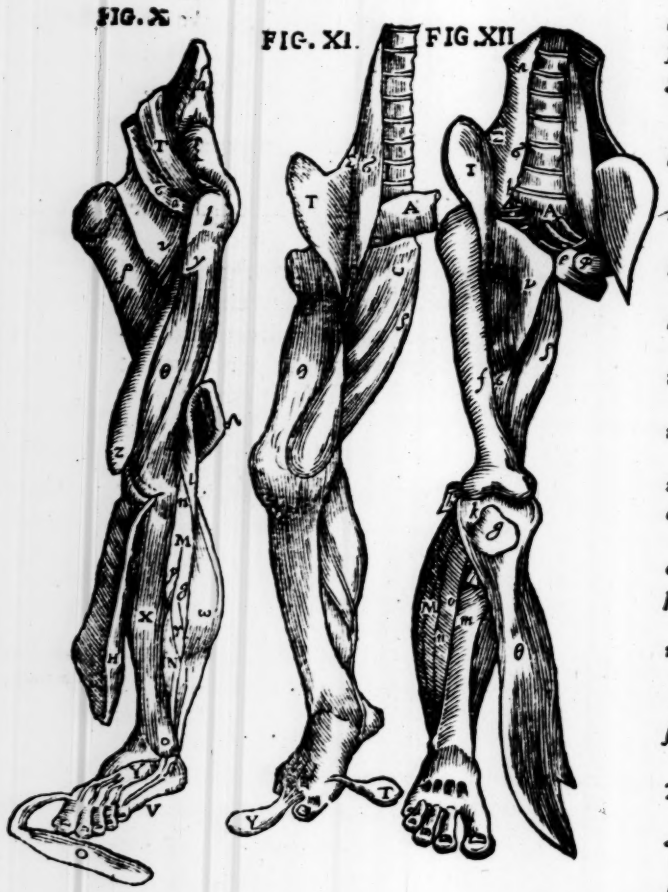
deſcending a little vnder the ioynt of the knee is confounded with the ſecond, and both together make a fleſhy and thicke muſcle which about the middle part of the legge after it hath formed the inner part of the Calfe [fig. 13, aboue c] becommeth narrower and endeth into a broad [fig. 13, f] and neruous tendon, in the middeſt whereof notwithſtanding a fleſhy portion ſheweth it ſelfe running a little way therein, which being vnited with the tendon of the next muſcle following, [fig. 13, and 14, ω] is in Apes inſerted into the heele but in men it groweth to the 4 extender of the foot, [fig. 14, '] in ſomuch that euen to the very heele it cannot be ſeparated there-from. And theſe three muſcles doe draw the heele vpward and backeward, and doe faſten the foote vpon the earth, or reflect it downeward and backward.

The ſecond extender.

The ſecond extender is called *Gaſtrocnemius externus, the outward Calfe-muſcle* [ta. 31, and thoſe that follow. fig. 3, 4, 10, 13, 14, ω] It proceedeth from the vtter head of the thigh, & is in all parts like the former, ſauing that the firſt deſcendeth fleſhy lower, which

Table 35. Sheweth ſome Muſcles of the Thigh, the Legge, the Foote and the Toes.

TABVLA XXXV.



a 10, the ſpine of the haunch-bone bared from the muſcles.
b 10, the greater exterior proceſſe of the thigh.
a b, 12, the originall of the firſt extender of the thigh at *a*, his tendon at *b*.
e 12, the ſhare-bone bared.
f, 12, the thigh-bone without fleſh.
g 12, the backpart of the whirle-bone regarding the ioynt, the tendons grow to the foreſide.
h 12, the tendon of the ſecond extender of the leg called *Vaſtus externus*.
i 12, the inſertion of the fourth bender of the leg called *Biceps*.
k 12, The connexion into one of the tendons of the 7, 8, and 9. muſcles.
l 12, The tendon of the ninth muſcle of the legge called *Rectus*.
m 12, the forepart of the leg bone without fleſh.
n 10, the original of the ſecond bender of the foote.
n 12, the forepart of the *Brace* bared,
o 12, A ligament placed betweene the bone of the leg and the brace.
o 10, the outward anckle.
p q 10, the body of the ſecond bender of the foot before and behind.
r 10, the beginning of the tendon of this muſcle ariſing out of the middeſt of his body.
ſ 10, The tendon of the third bender of the foot reflected to the outward ankle.
γ 10, the originall of the third extender of the leg called *Vaſtus internus*.
δ 10, the fourth bender of the leg called *Biceps*.
θ 10, 11, 12, the third extender of the leg called *Vaſtus internus*. *ζ* 10, the third extender of the thigh called *Glutæus minor*. *ρ* 10, 11, 12, the firſt muſcle of the thigh called *Triceps*. *σ* 10, 11, 12, the ſixt muſcle of the thigh called *Lumbalis*. *σ* char. 12, the forepart of the fift muſcle of the thigh. *τ* 10, 11, 12, the ſeuenth muſcle of the thigh called *Iliacus Internus*. *υ*, 10, 11, 12. the eighth muſcle of the thigh. *φ*, 12. The firſt Compaſſer of the thigh called *Obturator externus*. *ω* 10, the ſecond extender of the foote called *Gaſtrocnimius externus*. A 11, 12, the holy-bone. H 10, the ſecond extender of the leg called *Vaſtus externus*. M 10, 12, the ſecond bender of the foot called *Peroneus primus*. N 10, 12, the third bender of the foot called *Peroneus ſecundus*. O 10, the firſt extender of the toes called *Pollicis tenſor*. T 11, the lower abductor of the great toe. V 10, the abductor of the little toe. X 10, the bone of the leg without fleſh, with the ligament which runneth betwixt it and the *Brace*. Y 10, 11, the vpper abductor of the toes. *Z* 10, makes the muſcle called *Crureus*. Σ 11, 12, the firſt muſcle of the backe called *Quadratus*.

alſo

alſo may bee perceiued before Diſſection in thoſe bodies that are muſculous or fleſhy. This Muſcle not farre from his originall is ioyned with the firſt with fibrous tyes and groweth thereto at the middle of the Leg: [Tab. 13.d] and therefore *Syluius* and *Laurentius* call them *Gemelli* or the *Twinus*.

This Muſcle when it hath formed the outward part of the calfe endeth in a tendon which is ſo mixed with a Tendon of the former that it ſeemeth to bee but one Muſcle to *Columbus* and *Archangelus*, for they haue but one tendon and one implantation, and theſe two together with the fourth doe make the pulpe or calfe of the Leg.

But becauſe in the direction of the Leg thoſe heades are returned backward and ſo compreſſed; leaſt any offence ſhould thereby proceede, each originall hath a ſmall ſide-bone ioyned to it to receiue the violence and abate it in their ſmooth and ſlippery Surface which ſtandeth vp from the ſubſtance of the Muſcles, and doeth regard the ſmooth ſuperficies of the heades of the thigh whereuppon they leane. Theſe Seede-bones alſo doe keepe the Muſcles from attrition and laceration and adde ſtrength vnto them. The ſeede bones.

The third Extender is called *Plantaris* or the Muſcle of the palme or treade [Ta. 13. and thoſe that follow, fig. 7, 14, 16, n] It lurketh in the hamme vnder the former and is very ſlender. It ariſeth with a fleſhy and narrow originall from the outward head of the thigh neare the ioynt, but deſcending obliquely from the externall toward the internall part it is dilated: yet the fleſhy part thereof is ſmall, for preſently vnder the knee it determineth into a very ſlender neruous and exceeding long tendon [fig. 14. 15. 16. Ta. 31. fig 2. and 4. n] ſo long that among all the round Tendons of the body there is none longer. This Tendon is ſpread ouer the muſcle following, whereto in his progreſſe it is ſtrongly tyed and implanted into the inſide of the heele behinde. Sometimes it groweth broade and by the ſides of the heele is ſpent into the whole skinne of the palme or plant of the foote, as the palme muſcle in the hand. But when this muſcle (as it is with the muſcle of the palme of the hand) is wanting, then his tendon is ſubſtituted by the ſecond bender of the toes. His vſe is to writhe and turne the foote inward. The 3. extender.

The fourth Extender is called *Soleus* or the Muſcle of the Soale. [Tab. 31. and thoſe that follow, fig. 2, 7, 14 16, I] It is the greateſt and the thickeſt Muſcle of the foote and lyeth vnder the former Muſcles, and where the two firſt leane vppon it, it is liuid like them. It ariſeth neruous and ſtrong from the backepart of the *Fibula* or Brace, where it is articulated with the *Tibia* or Leg-bone, and becomming thicker it exceedeth in bredth both the bones of the Leg, but about the middle it is by degrees anguſtated or ſtraytned, and a little aboue the heele degenerateth into a thicke and very ſtrong Tendon, which on the foreſide is nouriſhed or encreaſed with a ſubſtance like fleſh farther then it is on the backſide, and being vnited with the Tendon of the firſt and ſecond Muſcles [Ta. 38. fig. 16. ω I] is implanted very ſtrongly into the backpart of the heele, where for this Muſcles ſake it is depreſſed and rough. His vſe is to extend the foote and firme it vpon the ground. The 4. extender.

But becauſe the bone of the heele ſtandeth out beyond the rectitude of the bone of the Leg, this tendon a little before his inſertion departeth from the legge [fig. 15. *] and maketh an empty cauity, through which the Butchers peirce their Cammockes to hang the beaſt vpon in the ſhambles; for in the whole body there is no Tendon ſtronger then it. *Hippocrates* calleth it *Chorda*, where he ſaith that vppon the fracture of the heele there follow dangerous Agues full of Hiccocks and conuulſions.

The fift and laſt Extender is called *Tibiæus poſticus*, the hinder Leg-muſcle. [Ta. 31. fig. 2, 7, 18, 19, K] It lyeth next to the bone betwixt the *Brace* and the *Legge* vnder two Muſcles which bend the Toes. The 5. extender.

It ariſeth from the two foreſaid bones [fig. 18, l] and preſently becommeth fleſhy and broade, deſcending fleſhy vnto the extreame appendix of the *Legge*, vppon which bone for the moſt part it lyeth through his length: it cleaueth alſo to a Ligament which lyeth betwixt theſe two bones, from whence haply his originall gathereth ſtrength; and in the middle of the *Leg-bone* from the inſide only it produceth a round neruous and ſtrong Tendon which tooke his beginning a little within the ſubſtance of the Muſcle. This tendon creepeth through a cauity grauen in the Leg-bone neare the inner ankle; vnder the tranſuerſe Ligament and obliquely attayneth vnto the ſoale of the Foote vnder the Muſcles which occupy the plant [Ta. 36, fig. 18, 19. m] or Treade, and is ſtrongly inſerted into the proceſſe which is on the lower ſide of the bone of the *Tarſus* or After-wreſt of the foote which is neare the Cube-bone, which proceſſe was onely created for his inſertion.

His

His vſe is to draw the foot inward, it helpeth alſo the motions of the firſt, ſecond & fourth Muſcles, and therefore moueth the foot to the earth, and ſometimes leadeth it backward, when we would ſtand vpon our tip-toes as we ſay. And thus much concerning the extending Muſcles of the foote on the backpart thereof. It followeth that we ſhould intreat of his bending or *anterior* muſcles which we ſayd are three.

The 1 bender

The firſt Bender is called *Tibiæus anticus*, the foreward Leg-muſcle, [Ta. 31. and thoſe that follow, fig. 1, 7, 8, L] becauſe it cleaueth to the forpart of the Leg-bone at his outſide.

It is the larger of the Benders and very nearly reſembleth a Snake and lyeth vppon the Muſcles of the Toes. It ariſeth acute or ſharpe neare to the *Brace* where it is articulated with the Leg-bone. Preſently it is dilated, and on the inſide of the Leg-bone it is ioyned to an acute line and becõing ſtreighter by degrees vnto the middle of the leg-bone determineth farre aboue the foote into a round, neruous and ſtrong tendon [fig. 2. and 18. n] which tendon alſo ſometime riſeth vp vnder the skinne, and growing from the lower appendix of the leg and the brace vnder the tranſuerſe ligament attaineth to the inſide of the foot, and couuayed in a reaſonable open cauity aboue the vpper part of the After-wriſt or the *Tarſus*, is wholly inſerted into the inner proceſſe of tha, bone of the wreſt of the foote which ſuſtayneth the great toe. His vſe is to bend the foote it ſelfe, and to draw it forward and vpward. This muſcle as alſo that that went before, eſpecially in that part where they are reflected vnder the wriſt and After-wriſt of the foote, haue a griſtle and ſeede bone allowed them by Nature to preuent their attrition.

The 2. bender

The ſecond bender called *Peronæus primus*, or the *firſt brace muſcle*, [tab. 31. and thoſe that follow fig. 1. 3. 8. 9. 10. 12. 16. 18. 19. M.] is in his whole progreſſe ioyned with the outſide of the precedent muſckle, and by it ſelfe is repreſſed in the outtſide of the leg. It ariſeth fleſhy and neruous [fig. 10. n.] from the vpper and outward part of the appendix of the *fibula* or *brace*, and becomming fleſhy it paceth along the ſame, cleauing ſom part to his ſide: departing from the *brace* it is on the outſide liuid, but on the inſide fleſhy and ruddy, and being conuayed a litle below the middle of the *brace* between two fleſhy ſides [fig. 10. p q.] out of the very middle of his body produceth an exceeding ſtrong tendon [fig. 10. r.] which is increaſed in the inſide on either hand with fleſh; which tendon becomming by degrees without fleſh, and reflected obliquely toward the backe-ſide of the appendix of the brace, and leauing the outward ankle naked [fig. 10. o.] beeing inuolued in a tranſuerſe ligament which proceedeth from the brace into the heel and the bone called the *cockall* or the *talus*, it paſſeth the fiſſure of the ſame outward ankle, and being very much reflected vnder the *plant* [tab. 36. fig. 19. tu.] is inſerted brode into the root of that bone of the wriſt of the foote which lyeth vnder the great toe. I ſay into the proceſſe which is on the outſide of that bone: ſometime into that bone vpon which the middle toe reſteth.

His vſe is to leade and bend the foote upward and outward. But this tendon paſſeth in the middeſt betwixt the bones and the muſcles of the plant or ſole of the foote [fig. 19. t u.] leaſt if it ſhould walke onely vnder the skinne when it is contracted vpward it might compreſſe the muſcles ſeated in the ſoale and hinder their functions. So alſo in the lower part of the *cube-bone*, there is a cauity ſomewhat brode but not deepe, ſineared ouer with a viſcide humor and compaſſed with a ſlippery ligament, at which the tendon is compaſſed not round leſt it ſhould fall thereout, but dilated [tab. 36. fig. 19, t] that ſo it might more firmely be reuolued at the ſhallow cauity. Againe the tendon in the ſame place is ſo hardened that it is like a gryſtle, yea ſometime ſo bony as if it were a ſeede bone, that it might better and more readily auoyde the violence of the bending or flexion at an acute angle.

The third.

The third and laſt bender called *Peroneus ſecundus*, the ſecond *brace muſcle*, [Tab. 31. and thoſe that follow fig. 3, 8, 9, 10, 18, 19. N] is hid vnder the former (his tendon excepted) and is like thereto. It ariſeth alſo with a long originall from the ſame appendix of the brace, and being fleſhy deſcendeth downe the ſame brace to which it is tyed, and when it hath ouercome the middeſt thereof, it departeth into a round tendon which is reflected toward the backeſide of the brace and is faſtened to the foreſide of the tendon of the ſecond bender, and lying vpon a cauity ingrauen in the backeſide of the appendix of the brace and compaſſed with the tranſuerſe ligament it deſcendeth forward: but at the vtter and lower part of the ankle it is againe reflected, deuided, and becommethforked, [tab. 35. fig. 10. ſ.] leſt it ſhould bunch vp too high and is implanted [tab. 36. fig. 19. x.] very ſtrongly

strongly with a double and broad insertion into the processe of that maner bone of the wrist of the foot which sustains the litle toe. His vse is to leade and bend the foot outward.

To these eight muscles of the foote *Vesalius* and *Fallopius* add a ninth [Tab. 33 fig. 8,9,P.] which *Bauhine* taketh rather to be a part of the second extender of the toes [ta. 33 fig. 7,8,9,P.] then a particular muscle of it selfe. And thus much of the muscles of the foot. *Fa'opius* ninth muscle.

CHAP. XL. *Of the muscles of the Toes.*

THe foure toes of the foote are moued almost with the same motions that the fingers of the hands are mooued with. But the great or thumbe-toe is not led after the same maner with the thumb of the hand, that is, with a flexion opposit to the other fingers. But his first ioynt is bent after the same manner with the first ioynts of the rest of the toes, because his position is in the same order. The toes therefore are moued directly or sidelong. If directly, then either they are bent toward the earth, euery ioynt being mooued apart, and that either directly onely, as the second and third ioynts of the foure toes, and the second of the thumbe or great toe; or directly & obliquely together, as the first ioynts of all the fiue toes. If they be extended, the extention is made directly or in a right line, and so all the ioynts are moued together. If they moue to one side that motion is either outward, as when the foure greater are led to the little toe, and the litle toe led from the rest; or inwarde when the thumbe-toe is ledde from the rest and the foure lesser toes moued toward it. All these motions are absolued by three and twenty muscles, whereof some are seated in the leg, that is to say, part in his fore part & part in his backpart. Others are placed in the foote it selfe, properly so called. The motion of the toes. Their muscles 23.

The first muscle of the toes is called *Pollicis tensor, the extender of the great toe or the first extender*, [Tab. 33, fig. 8,9,°] It is seated in the foreside of the legge, together with that which next followeth at whose inner side it lyeth. First.

It ariseth fleshy from the outside of the legge where the bone of the leg or the *Tibia* departeth from the *Brace* or the *Fibula*. After it descendeth and groweth in his whole passage to a membranous ligament which commeth betwixt the leg & the Brace bones and so attaineth vnto the foreside of the leg; thence creeping vnder the transuerse ligament [Tab. 31, fig. 1, char. 2] and ouer the foote, it is inserted into the vpper part of the whole length of the great toe to extend it. Sometimes the tendon is diuided into two, one of which is inserted into the last ioynt of the great toe, the other into the wrist of the foote to bend it. And this latter tendon in some bodies seemeth to be a distinct muscle. But that saith *Columbus* is very rare.

The second extender [Tab. 31, and those that follow fig. 1,3,7,8,9,P] is placed in the forepart of the leg, but lurketh vnder the sixt muscle of the foote. It ariseth with an acute and neruous originall [Tab. 33, fig. 8, char. 10.] which presently becommeth fleshy, from the top or extremity of the appendix of the leg, where vnder the knee it is fastened to the Brace; thence it descendeth directly along the Brace and about the middle thereof it casteth off from his outside a fleshy portion, [tab. 31, & those that follow fig. 8,9,P] which portion descending downeward, maketh that muscle which *Fallopius* calleth the ninth muscle of the foote: presently falling yet lower vnder the transuerse ligament which is on the foreside of the leg, [tab. 31, fig. 1, char. 2,] to which it adhereth; at the end of the *Fibula* or *Brace* it degenerateth into a tendon, [tab. 33, fig. 8, charact. 12,] which tendon before it passe the transuerse ligament is diuided into foure round tendons separated & conueyed through the backe of the soale vnto the foure toes, (beside the great toe) which run through their whole length, and becomming broader are inserted into their vpper parts. Their vse is to extend the three ioynts of the foure toes together. Second. Fleshy parts.

The third muscle of the toes is called *Pollicis Flexor, the bender of the great toe, or the first bender*, [ta. 31, and those that follow, fig. 2,7,16,17,°] and is seated with that which next followeth in the backpart of the leg vnder the muscles, which make the *Pulp* or *Calfe*, and it is almost altogether fleshy. Third.

It ariseth [figure 16, character 13,] from the backe-part at the connexion or conjunction of the *Brace* with the Legge-bone, and growing for a time to the *Brace*, it approcheth to the ende of the Legge-bone, where from his inside there issueth a rounde Tendon, [figure 16,17, character 14,] which may bee seene manifestly to haue his originall out of the flesh, [Table 36, figure 16, ω] which tendon passeth obliquely vnder the Ankle at the inside of the heele, where a cauity is engrauen for it, and

where alſo it is couered with a tranſuerſe ligament: thence it inclineth vnder the plant or treade of the foote, at which place ſometimes it tranſmitteth certaine ſmall portions into the tendons of the third muſcle with which it is commixed, [fig. 16, cha. 19] and when his ſpeciall tendon is receiued by the tranſuerſe ligament, it is inſerted with a broade implantation into the ſecond bone of the great toe after it hath paſſed the length of the firſt, which ſecond bone it bendeth. Sometime vnder the ſoale it is diuided into two tendons the larger wherof it tranſmitteth to the great toe, the leſſer vnto the next, and then the ſecond bender is diuided onely into three tendons and no more. This tendon before it is inſerted into the ſecond bone of the great toe hath a great ſeſed-bone ſet before it with a ſlippery and ſmooth ſurface.

The fourth. The fourth Muſcle of the Toes or the ſecond Bender which is called *Digitorum flexor magnus*, the great Bender of the Toes [tab. 36. fig. 16, 17, 18, R] lyeth neare the former and leaneth rather vpon the Legge then vpon the Brace-bone [table. 36. fig. 18, rather A then B.]

It ariſeth fleſhy from the Leg-bone vnder the hamme [fig. 16. cha. 8] and deſcending almoſt to the heele, it produceth from the inſide a round tendon [fig. 16 char. 7.] which paſſing along vnder the inner ankle, and in a peculiar cauity of the heele [fig. 19, ⁿ] and vnder the tranſuerſe Ligament which groweth from the appendixe of the Legge, it runneth vnder the tendon of the third Muſcle in the ſoale of the Foote with which it maketh a decuſſation [fig. 17. betwixt the 17, and the 15, characters] and in the middle of the foot is deuided into foure tendons, [fig. 17, char. 18.] which being bound with Ligaments and paſſing through the Section or diuiſion of the Tendons of the ſubſequent muſcle are inſerted broade according to the length of the bone into the third ioynt of the foure Toes. The vſe of this Muſcle is to bend thoſe foure toes, to contract them ſtrongly and to lead them one to another.

The fift. The fift Muſcle is alſo the third bender. [ta. 36. fig. 16, 17. S] It is ſeated vnder the middle of the ſoale and ariſeth with an originall mixed betwixt a neruous and a fleſhy from the lower part of the heele-bone, and the forepart of his protuberation. Preſently after his originall it becommeth fleſhy and paſſeth toward the Toes, being by degrees dilated or ſpread abroad according to the forme of the foote. At the middeſt whereof it is deuided into foure fleſhy parts; [ta. 36. fig. 16. char. 21.] which parts being ſeparated doe each of them produce a round tendon which are receiued at the roote of the firſt ioynt by the tranſuerſe Ligament, and being deuided (as it is in the hand) with a long ſection each of them growing broade, are inſerted into the ſecond bone of the foure Toes.

The vſe of this Muſcle is to bend the ſecond ioynt of the foure Toes. There alſo groweth very ſtrongly a broade tendon [ta. 34. fig. 15. Z] vnder all the fleſhy ſubſtance of this Muſcle, which ſerueth inſteade of the broade tendon of the hand, and ſometimes is the tendon of the third muſcle of the Foote which is called *Plantaris*. This tendon is of exquiſite ſenſe the better to forwarne vs vppon the inſtant of externall iniuries.

[*Table 36 is the ſame with* 31. *Folio* 806.]

The ſixt or The ſixt Muſcle is called *Abductor pollicis inferior*, the lower backe-leader of the great Toe. [tab. 31. and thoſe that follow, fig. 1, 2. 7, 11, 16, ᴮ] It lyeth to the inſide of the Foote throughout the length thereof, and reſembleth the faſhion of a Mouſe. His originall is neruous from the heele on the inſide neare the muſcle foregoing, and becomming fleſhy it is faſtned to that bone of the wreſt of the Foote which ſupporteth the great Toe, & degenerateth into a round tendon which is implanted on the outſide into the firſt bone of the ſaid great Toe to lead it from the reſt.

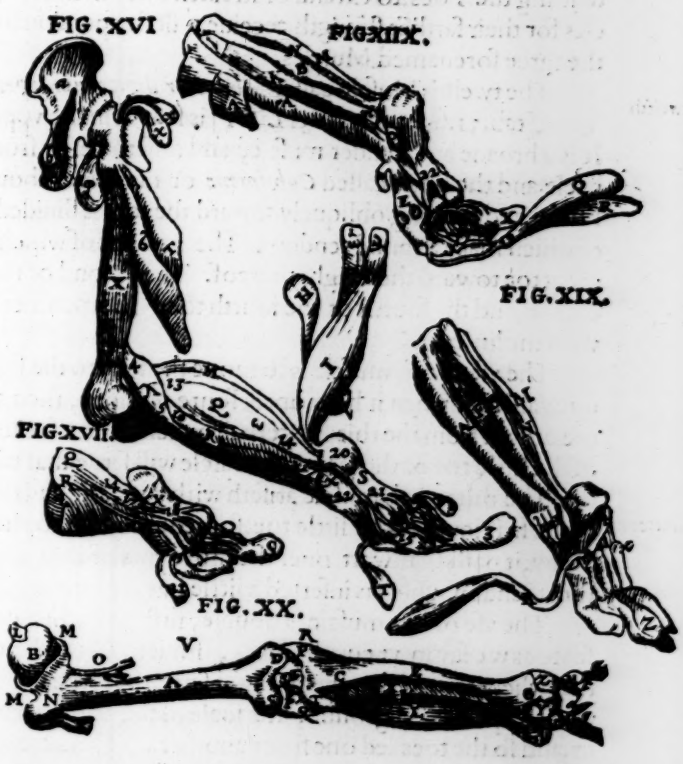
The ſeauenth The ſeauenth Muſcle is called *Abductor minimi digiti inferior*, the lower back-leader of the Little Toe. [tab. 31. and thoſe that follow, fig. 3, 4, 15, 16. V] It is ſituated in the externall part of the Foote and ariſeth with a neruous originall from the vtter part of the Heele where there is a protuberation, and becomming fleſhy it expreſſeth the forme of a perfect Muſcle, and is affixed to that proceſſe of the wreſt-bone which ſuſtaineth the little Toe, and determineth into a round Tendon which is infixed into the outſide of the firſt bone of the little Toe to lead it from the reſt.

These three are couered or inueſted by a thicke and broade tendon as it was in the palme of the hand.

The 8. 9. 10. & 11. The 8. 9. 10. and 11. Muſcles, or the 3. 4. 5. and 6. Extenders, called alſo *Lumbricales*, the

Table 38. *ſheweth the Muſcles of the Foote and the Toes thereof. But the* 18. *the* 19. *Figures ſhew the right Foote as did thoſe two in the* 34. *Table, but here it is more bared from the Muſcles.*

TABVLA XXXVIII.



a 16, The backe of the hanch bone bare.
b 16. A membranous ligament occupying the greate perforation of the ſharebone.
l m 18. The beginning of the fift extender of the Foote at *l*, his tendon at *m* 18, & 19.
n 18. A portion of the Tendon of the firſt bender of the foot.
p 16, The tendon of the 3. muſcle extending the foote.
q m 19. the 2. bender of the foot or the firſt *Peroneus* reflected in the ſoote.
x x 16. two fleſhy partes compaſſing the Tendons of the tenth muſcle of the thigh.
x 19. The inſertion of the 3. bender of the ſoote.
A 18, 89, The bone of the leg.
B 18, 19. the *Brace*.
C D 18, The boſome or cauity of the tendons o the 2, and 3, muſcle f the toes
E 18, Small bones neare the firſt ioynt of the great toe.
F 19. a ligamẽt going betwixt the bones of the leg and the *Brace*.
H 16, the 3, extender of the Foote called *Plantaris*. I 16. the 4. extender of the foote called *Solens*. K 18, 19, the fift extender of the foote called *Tibiæus poſticus*. M 16, 18, 19. the 2, bender of the foote or the firſt *Peroneus*. N 18, 19. the 3, bender of the foot or the ſecond *Peroneus*. Q 16, 17, 18, the firſt muſcle bending the toes of the foote or the bender of the great toe. R 16, 17, the ſecond bender of the toes or their great bender. S 16, 17, the 3 muſcle bending the toes or their other bender. T 16. the lower *abductor* of the great toe. V 16, the *abductor* of the little toe. X 17, 18, the foure muſcles called *Lumbricales*. Z 16, the muſcles called *Interoſſei* or the bone bound muſcles. λ 16, the muſcle mouing the Leg obliquely called *Popliteus*. ο 16, the firſt bender of the thigh called *Lumbalis deſcendens*. π 16, the 2, bender of the thigh called *Illiacus internus*. ρ 16, a portion of the firſt compaſſer of the thigh. ϕ 16, the firſt extender of the foot called *Gaſtrocnimius internus*. ω 16, the ſecond extender of the foote called *Gaſtrocnimius externus*. * 16, the thigh bone bare. 1, 2, 3, Char. 19, three *Sinus* or boſomes made to carry three tendons. 3, char. 16 a ligament hanging from the ioynts of the Toes, doing the office of the broad tendon. 4, 5, char. 16, the originall of the muſcle of the ham called *Popliteus* at 4, his inſertion at 5. 13, char, 16, the originall of the firſt bender of the toes. 14, 15, char, 16, 17. the tendon of that muſcle at 14, his inſertion at the great Toe 15. 16, char, 16, the beginning of the ſecond bender of the toes. 17, cha, 16, 17, the tendon of the ſame ariſing there. 18, char, 17, the tendon deuided into foure parts. 19, char, 18, the commixtion of the tendons. 20, 21, char, 16, the third bender of the toes, his originall from the heele at 20, his diuiſion into foure tendons at 21. 22, char, 16, 17, 18, a fleſhy portion growing to the bones of the foote at the great toe,

Figure 20, *ſheweth the Ligaments growing to the ioynts and the Bones of the Leg & the Thigh.*

A B, The thigh bone at A his vpper head at B. C D, the 2 lower heads thereof. E, the bone of the leg. F, his vpper protuberation. G, the lower *ſinus* or cauity. H, the inner ankle. I, the *Brace-bone* called *Fibula*. K, the vtter ankle. L the vpper, a round ligament of the head of the thtgh. L the lower, a muſcle in the calfe or the fourth of the foote. M M, a ligament compaſsing the vpper ioynt of the thigh. N, A ligament growing to the greater proceſſe of the thigh. O, A Ligament affixed to the leſſer proceſſe of the thigh. P P, a ligament involuing the ioynt of the knee. Q R, a ligament ſet to the vtter and inner ſide of the knee. S, a ligament coupling the protuberation of the leg-bone marked with F and the thigh together. T V, a ligament binding the leg-bone and the *Brace* together aboue and below. *X*, a membranous ligament faſtning together the Leg and the *Brace*. Y Z, a tranſuerſe ligament gathering the nerues. α a tendon made of three muſcles of the foote and inſerted into the heele. *a b*, ligaments ioyning the heele to the *Leg* and the *Brace*: from the bone of the leg to the heele at *a* from the *Brace* to the heele at *b*. *c d*, A griſtly Ligament running from the inner Ankle into the inſide of the *Talus* at *c*: another ioyning the *Brace* to the *Talus*.

the wormy Muscles [tab.36.figu.17,18,x] are seated vnder the soale of the Foote, and arising from the Ligament which compasseth the foure tendons of the perforating Muscle or the second Bender, are implanted round and small into the Tendons of the Muscle extending the Toes, to extend or streatch forth their second or third ioynts. These Muscles for their farther strength receiue a fleshy portion from the heele, which lyeth vnder the three forenamed Muscles.

The twelfth

The twelfth Muscle called *Abductor digitorum superior*, the vpper backe-leader of the Toes, [tab.31.fig.1,8,9,10,11,T Y] is seated in the vpper and gibbous part of the Foote. It is a broade and slender muscle, and ariseth fleshy from the Ligaments which are at the heele and the bone called *Cubiforme* or the Dye aboue the wrist and After-wrist of the Foote, and running obliquely toward the toes is diuided into foure fleshy parts euery one of which make a round tendon. The greatest of which is inserted in the vtter side of the great toe toward the height thereof. The second of the next toe. The third of the middle toe, and the fourth of the fourth toe. Sometimes also but rarely a small part is lent vnto the little toe.

The vse of this muscle is to moue the toes to the sides and to leade them backward & outward. But when it hath onely foure tendons, then the tendon belonging to the little toe ariseth from the third externall muscle of the foote although the lower backe-leader of the little toe or the seauenth muscle will serue that turne.

The thirteenth

The thirteenth muscle ariseth with a broade and neruous original from the ligament of the first ioynt of the little toe, sometime of the toe next vnto it, afterward becomming fleshy, it passeth thwart ouer the first ioynts of the toes and determineth in a broade but short tendon which is inserted a little inward into the first ioynt of the great toe.

The vse of this muscle is double, first that when it worketh wee may better hold our feete as we say in vnequall places, for it maketh a kinde of apprehension. The second that when it worketh not, it might serue the foote in stead of a ligament, least when wee walke vppon euen ground, the soale of the foote should be enlarged beyond that that is fit, and so the toes led one from another. Concerning this muscle saith *Bauhine*, *Iulius Casserius* first writ vnto me.

Casserius.

The ten muscles betwixt the bones.

Vnder this muscle lye the ten muscles called *Interossei* or the *bone-bound* muscles (for you must giue vs leaue to make englisn words as our Authors haue done in greeke and latine) [tab.36,fig.18,19,*] which are to be referred to the benders of the toes. These haue their situation in the soale of the foote where they make a rude and indigested lump of flesh diuersified with right fibres, which lumpe proceedeth from the beginning of the after-wrest, and passing throughout his length fill vp the spaces betweene the bones and are inserted two and two into the rootes of all fiue toes or at the ligament of the first ioynt toward the inside, that so when two worke together, they may bend the first ioynt, but when one alone worketh, it leadeth the same ioynt to the side eyther outward or inward as the site and originall of the muscle is. To the short and broade tendons of these muscles do grow for their further strength seed-bones, such as are in the hands, but greater.

The conclusion of the muscles.

And thus haue we brought to an end this crooked and crabbed history of the muscles cõcerning which, I know not whether I should rather craue pardon or pitty, pardon I presume I shall not neede to craue of them that vnderstand through what a laborinth I haue led my pen: pitty also will do me little good now the paine is past. Acceptance shall bee better welcome then eyther, and an ingenious mind that measureth my foote by his own Last. One other passage remaineth in this booke, and that is concerning those other kindes of flesh which are found in the body of man, to wit, the flesh of the *viscera* or *Entrals* and that of the Glandules, which two when we haue lightly passed ouer, we will proceede vnto the booke of the Vessels.

CHAP. XLI. *Of the flesh of the Entrales or Bowels.*

Parenchyma what it is.

Galen esteemed the flesh of the Bowels to be similar and simple, not onely in respect of the mistion, because all euen their least particles are of one and the like nature, whence some Arabians haue called it *Confusa*. *Erasistratus* called it first of al men παρεγχυμα as it were an affusion or cocretion of blood. This flesh *Erasistratus* esteemed to haue no other vse but only to separate the vessels and to serue as a soft cushion or pillow for them to rest on, and to strengthen and establish their passage, but we esteeme it to be of a great deale more excellent vse, for wee thinke

thinke that it is the chiefe part of the bowell to which the officiall or common action thereof primarily appertaineth. So Sanguification primarily and of it selfe belongeth to the Flesh of the Liuer; to the veines secondarily onely and by influence. His excelencie.

The Flesh of the Longues prepareth the aire for the Heart, the Flesh of the Spleene purgeth the Lees or fœculencie of the bloud, the Flesh of the Kidneies draweth and separateth the whey or vrine. Wherefore this Flesh maketh the proper substance of the bowell or entrall. Onely this among all sorts of Flesh is insensible, and according to *Galens* testimony *in Arte parua* is of the number of those partes which haue their faculties seated and established in them not influent or deriued from other parts.

The Flesh of the Liuer is red and moderately thicke, neither doeth the heate thereof alone further the sanguification of the veines, as the Kell, the Spleen and the parts thereabouts doe assist the concoction of a Stomacke: But by an in-bred and proper power it sealeth or imprinteth vpon the bloud his stampe or forme his temper and colour. Of the Liuer.

The Flesh of the Spleene is a rare spongy or funguous *Parenchyma*, loose like the faster sort of sponges, and fit to draw and receiue muddie and melancholique humors. Of the spleen

The Flesh of the Kidneies is red, fast and solid, differing not much from the substance of the Heart, sauing that it is not intertexed or wouen with fibres. It was made solid, least if it had beene loose and flaccid it should not haue beene able to containe the vrine that it receiued. It draweth by an inbred power whey or vrine from the whole body, separateth it being mingled with the bloud, and transfuseth it drop by droppe into membranous cauities. Of the Kidneies.

The Flesh of the Longues is light, rare and like vnto a sponge, made as it were of the froth of bloud congealed together. It is light that it might easily be lifted vp, and fall againe without violence, and so readily obey or follow the motions of the Chest. It is rare and spongy that like a paire of bellowes it might presently be filled with the ayre we breath in, as also to make the way fit for the breathing out of sooty and smoaky vapours. This Flesh prepareth for the Heart one of the materials of the vitall spirit, that is ayre, for the outward ayre which hath much impurity mixed therewith, could not at the first hand be made a fit nourishment for the inward spirit, & therefore it was necessary that it should be altered by little and little, and by some stay made in the Lungs, acquire or attaine a quality familiar to the inbred spirit. Of the Lungs

Concerning the flesh of the heart, it may be doubted whether it ought to be referred to the flesh of the bowels or to the flesh of the Muscles: *Galen* holdeth on neither side; for a *Parenchyma* hath no fibres, the Heart is wouen with them after a strange and admirable manner. Againe, the motions of the Muscles are Voluntary, so is not the motion of the Heart. The Flesh therefore of the Heart is peculiar to it selfe alone, such as you cannot finde in the whole body againe. Of the heart.

There is no lesse scruple also concerning the Flesh of the Tongue, for it is as nimble as an Eele; turning it selfe into a thousand motions, yet are there no fibres running therethrough, and therefore the Flesh thereof cannot be sayde to bee musculous, rather if all things be considered it inclineth to the nature of a *Parenchyma*. And so much shall be sufficient to haue said concerning the Flesh of the Bowels or Entrals.

CHAP. XLII. *What a Glandule is, and how many kinds there be of them.*

BEcause many of the Ancients haue defined a Glandule to bee a *Flesh rowled vp into it selfe*: I haue thought fit sayth *Laurentius* for order sake to refer the whole kinde or kin of Glandules vnto Flesh. What a glandule is.

A Glandule therefore which the Græcians call ἀδὴν is a simple part, Rare and fryable, soft like a sponge, appoynted by Nature to firme and establish the vesselles, to sucke or drinke vp superfluous humours, and to water or dew some partes that stoode need of moysture.

The Author of the Booke *de Glandulis*, whether it were *Hippocrates* or *Polybius*, hath elegantly expressed the nature of a Glandule, where hee sayeth *Their Nature is spongy for they are rare and fat.* That they are of such a nature you shall easily find if you presse them hard betwixt your Fingers, for they will yeilde an oylie humour and bloud, white like phlegme. Now it is consonant to reason that they haue such a substance, not for nought but for some particular and especiall vse. That vse is three-fold.

The first vse of glandules.

The first vse of Glandules is to firme or establish the diuarications or diuisions of the vessels. For it was to be feared least the vessels running through large and ample cauities, if they had no other muniment or defence sauing their owne membranes, would in violent motions be broken off, as in great windes boughes are torne from a tree; vnlesse these glandulous bodies did lye soft vnder them and establish and sustaine them. And therefore where the vessells are forcked or deuided, there Nature hath euer placed Glandules vnder them.

So in the diuision of the Gate-veine there is a notable Glandule called *Pancreas* or the Sweete-bread. In the diuarications of the veines of the Mesentery there are Glandules almost infinite. In the distribution of the ascending trunke of the hollow veine is the glandule called *Thymus* which is the sweetebread in calues. In the vessels of the braine the glandule called *Conarium* or the pine-glandule. In the the necke, in the arme pits and in the groynes where the *Iugular axillary* and crurall veins are diuided there are glandules placed to support their diuisions. VVherefore they were made soft and rare, that neyther their hardnesse might offend the vessels, and by yeelding they might giue way to the distentions when they strut with blood.

Their second vse.

The second vse of the glandules is like sponges to sucke and drinke vp fleame, whey and other superuacuous humours, that they should not rush vpon the more noble parts. In which respect their forme is round, somewhat long, and their substance rare and open; so fitted to receiue the greater quantity of any kind of influxion. This vse the authour of the booke *de glandulis* openeth vnto vs in these words. They beare away the redundancie or surplussage of the rest of the body, and that indeede is their familiar Alement. It may also by reason be demonstrated that they were ordayned by nature to purge away moyst superfluities; for those parts that are hollow, and especially if they bee moyst and full of blood, haue more and larger glandules then those that are solide and lesse succulent, as are the ioynts. So behind the eares about the necke where the iugular veines run, about the arme pit where the axillary branch is, and about the groynes where the crurall veine appeareth, there are notable glandules which receiue the superfluities of the principall parts, the Brayne, the Heart and the Liuer, which glandules are commonly called *Emunctories*, and if they swell or bee otherwise affected, they betoken the distemper of their owne bowell or some ill disposition therein. *Hippocrates* in the second section of his 6. booke *Epidemion*, saith *Abscesses* or *Apostemes* (as for example the tumors of the glandules) are produced as fruiteless water shootes of those places, out of which they grow. They also bewray the condition of other places and parts, and especially of the bowels. *Galen* also in the thirteenth booke of his Methode saith, that when an Apostemation ariseth neare any notable artery or vein sudainly do spring vp *Bubones*, that is, inflammations of the glandules.

The thire vse.

Thirdly we added in the definition, that the vse of the glandules was to irrigate or water some parts lest they should too easily bee exiccated and dryed or made vnfit for motion. Such are some of the glandules of the Mesentery, which with their moysture do dew the guts. Such are also the glandules of the Throttle or the Tongue, which ingender or gather spittle. The glandules in the corners of the Eyes doe make much toward the celerity and ease their motions, and finally those prostate glandules in the neck of the bladder doe water and moysten the Vreter with an oyly humidity, lest it should bee offended by the Acrimony of the vrine. And this is the nature of glandules properly so called.

Glandulous bodyes.

There is also another kinde of glandules which may more truly be called *Glandulous bodyes*. Their substance indeed is like vnto a glandule that is rare and lax, but it is ordayned by Nature for the generation of humours or iuyces which are profitable for the creature. Proper or simple glandules haue neither peculiar veines, nor arteries, nor nerues And according to *Galen*, they are in the last of those parts which haue faculties inbred & seated in them, not flowing from otherwhere: but these glandulous bodyes haue manifest and conspicuous vessels, and are also of exquisite sense. The former haue onely an vse in the body: these latter haue not onely an vse, but doe also performe an action. So in *Galen* the Testicles are called glandulous bodyes: for their substance is soft and hollow, in which the seede is boyled and perfected. So the dugs are glandulous bodyes and haue a power or faculty in them for the generation of milke. Notwithstanding these glandulous bodyes doe sometimes affoord the same vse that the other glandules doe, that is, to sucke or sup vp the recrements or excrements of the whole body: for Nature doth often abuse

one

one and the ſame part to diuers vſes. So *Hippocrates* reckoneth the Kidneyes in the number of the Glandules, yea and the braine it ſelfe *is like vnto a Glandule, for it is white and friable* and performeth the offices of a Glandule to the head.

CHAP. XLIII. *A briefe enumeration of the Glandules in the whole body.*

THE number of the Glandules is almoſt infinite, we will onely run ouer the moſt notable, and of them giue you but a light view, becauſe you haue heard their particu ar deſcriptions in their proper places.

In the braine there are 2 Glandules not very great indeed but very notable. The first is of a turbinated figure commonly compared to a pine-kernell and called *Conarium*; of which you ſhall reade in the twelfth chap. of our ſeauenth booke. It is thought to be ordained for an eſtabliſhment vnto the veines and arteries which are diſperſed into the braine, and maketh the way open for the Animall ſpirit out of the thirde into the fourth ventricle. The other is called *Glans Pituitaria*, the phlegmaticke Glandule; of which you ſhall reade in the thirteenth chapter of our ſeauenth booke. The glãdules in the braine.

His porous or open fleſh like a ſponge receiueth the ſuperfluities of the vpper ventricles of the braine, and diſtilleth them into the Pallate through the holes of the wedge-bone. Vnder the eares and behind them there are many glandules called Parotides appointed to eſtabliſh the diuiſions of the veſſels, and to drink vp the humors of the braine, whoſe Emunctories they are commonly ſtiled. Betwixt the skinne and the fleſhy membrane of the Face there are many glandules, ſayth *Platerus*, which they call Animelles, as alſo betwixt the lower ſide of the puffe of the cheeke, and the beginning of the necke, where the Kings euill doth often ariſe.

In the inſide of the chops which from the narrownes is called *Iſthmus*, there do appeare two glandules like blanched Almonds, and therefore they are called the Almonds of the throate and Tonſillæ, and theſe do perpetually moyſten the chops, the mouth, and the tongue with ſpittle. There are alſo two at the roote of the Larinx or throttle, and two vnder the gullet, which often-times do ſo ſwell that they interclude the way both of meate and drinke: but of drinke eſpecially, for the ſolid meate makes it ſelfe a way by cõpreſsion, wheras that which is liquid doth rather fil the fungous ſubſtance of the glandule. The glãdules of the Larinx.

Vnder the top of the breſt-bone, in the very diuiſion of the aſcending trunke of the hollow veine there is a glandule called *Thymus* a lecker or ſweete-bit for nice pallats, made to eſtabliſh the veſſels.

There are alſo many others in the cauity of the cheſt, in the arme-pits, in the groynes, in the armes and in the legs. All which want proper names.

Vnder the Stomacke and the Gut called *Duodenum*, there is a glandulous body, which becauſe it reſembleth a ſimple fleſh, they call *Pancreas*, whoſe vſe is to ſuſtaine, imbrace and comprehend the branches of the Gate-veine, which are to be diſtributed into the ſtomacke, the gut *Duodenum* and the Spleene, which are onely ſupported by the lower membrane of the Kell.

In the Meſſentery there are many Glandules as well to diſtinguiſh the veſſels as to keepe them from compreſsion, when the guts are ouer-filled or when the *Abdomen* is too much ſtrained, for otherwiſe the tranſcolation of the chylus would be hindered. Theſe Glandules alſo do moyſten the guts, and tye as it were the veſſels together that in violent motions they might not bee broken. In the necke of the bladder neare the ſphincter muſcle are thoſe glandules which are called *Proſtatæ*, of whoſe vſe we haue ſpoken partly in the fourth booke, and partly in the former chapter.

The Glandulous bodies we neede not in this place ſo much as to rehearſe for their deſcriptions arè large enough in their proper places; whereto we referre the Reader, and heere put an end to our booke of Fleſh: and proceede vnto the Veſſels.

The end of the tenth booke.

THE ELEAVENTH BOOKE,
Of the Veſſels vvhich hath three parts:

The firſt of the Veines.
The ſecond of the Arteries.
The third of the Sinewes.

The Præface.

AS in the Heauens the Angels are the Meſſengers of God, carrying down his commandements vnto men whome alſo they guard and defend; ſo in this *Microcoſme* the dull Fleſh being of too ſlow a kind to enſue the noble motions of the Soule, which with his counterpoiſe it oftner doth oppreſſe, our wiſe Creator ordained ſpirites of a middle Nature betweene the Soule and the Body, which like quicke Poſtes, like Purſeuants or Heralds might traſuell betweene them, and communicate their commiſſion to the particular partes which they receiue either at the firſt hand from the Soule it ſelfe in the Brayne, or haue it ſealed in the Heart or the Liuer, as in her ſubordinate offices.

Theſe Spirits *Galen* calleth ὁρμῶντα Impetuous bodies, becauſe their motion is ſudden & momentanie like the lightning, which in the twinkling of an eye ſhooteth through the whole cope of Heauen; yea ſo much more ſubtle are they then the Lightning, as that the one is viſible the other inuiſible: or they are like the winde which whiskes about in euery corner and turnes the heauy ſaile of a Wind-mill, yet can we not ſee that which tranſports it. How neceſſary therefore was it that ſuch ſubtle and vndertaking or actiue Creatures ſhould be confined as well to guide their motion which otherwiſe would be inordinate, as alſo to keepe them from exhaling or vaniſhing away. Nature therefore becauſe the Spirites are of three ſorts, Naturall, Vitall and Animall, hath prepared three kindes of Veſſelles for their tranſportation, Veines, Arteries and Sinewes. The Veines becauſe their gueſt is not ſo ſubtile but a more cloudy and thick ſpirit, generated immediately out of the purer ſubſtance of the bloud, haue but a ſingle coate, as being ſufficient to conteine a more quiet ſpirit. The Arteries becauſe their ſpirits are more ſprightfull and impetuous, mouing alwayes with a ſubſultation, and perpetually playing vp & down, are made as ſome thinke ſixe fould as thicke as the Veines, the ſafer to immure the vnruly Inmate. The Nerues are nothing elſe but productions of the marrowy and ſlimy ſubſtance of the Brayne, through which the Animall ſpirits do rather Beame then are tranſported, inueſted with the two Membranes wherein the Braine it ſelfe is inueſted, commonly called the *Pia* and *Dura mater*. And this ſubſtance was indeede more fit for Irradiation then a conſpicuous or open cauity, which would haue made our motions & Senſations more ſudden, commotiue, violent and diſturbed, whereas now the members receiuing a gentle and ſucceſsiue illumination are better commaunded by our Will and moderated by our Reaſon.

The Natures of theſe three kindes of Spirites wee haue partly handled before in the third, the ſixt and the ſeauenth Books: & therefore we will no longer detaine the Reader by way of Introduction, but deſcend vnto their particular Hiſtories.

CHAP.

CHAP. I. *What a Veine is.*

HAuing wrought our way through the darke and shady groue of the muscles *Nulli penetrabilis astro*, into the secret whereof I thinke no wit of man is able to reach. (And therefore it shall be no wonder if we bring some scratches out of so thorny a copse) we are now arriued in these medows, where the vessels like so many brooks do water and refresh this pleasant Paradise or modell of heauen and earth; I mean the body of man. And surely by these streames doe grow many pleasant flowers of learning to entertaine and delight our minders beside the maine profit arising therefrom vnto the perfection of that art we haue in hand.

Vnder the name of vessels we vnderstand three kinds veines, arteries and sinewes, because out of these as out of riuers, doe flow into all the parts of the body Blood, Heat, Spirits, Life, Motion and Sense. Three kindes of vessels.

Wherefore *Hippocrates* in his booke *de Corde* calleth them ποταμοὺς ἐνόσου ἀνθρώπου, the riuers of the body of man. Neither let any man taxe vs for inuerting our order when wee first begin with the history of the veines, then descend vnto the arteries, and lastly vnto the nerues; because the veines are most simple as hauing but one proper coate and that thin; the arteries two and those thicker; but the substance of nerues is manifold, as being within soft and marrowy without membranons. For they must remember that the maine guide of our labour is the order of dissection. Now the originall of the veines is in the lower region, at which we began our discourse. The originall of the arteries in the middle region, and that of the nerues in the vpper.

A veine therefore is by the later Greeke writers absolutely called φλὲψ. *Eudox.* calleth it ἀνθρωμοὺς, *Hesychius* ἑξαιμίην, because it is the canale of the blood. The Antient Physitions, as *Hippocrates* vsed φλὲψ as a common name to veines and arteries, so in his booke *de carnibus*, *There are two* κοῖλαι φλέβες, saith he, *two hollow veines issuing from the heart*: the one is called a veine, the other an arterie. Sometimes *Hippocrates* distinguisheth betwixt these two veines by adding the word σφύζειν, which signifieth to beate, as if he should say arteries are beating veines, veines those that doe not beate. Many places might be alledged to proue this distinction if wee thought it needfull: *Auicen* cals the arteries beating and hold veines. *Cicero venas micantes* which doe sometimes lift vp themselues, and sometimes sinke againe. *Celsus* calleth them veines fitted for the spirits, and the true veines he cals *quietas*, *still* veines. *Hippocrates* in his booke *de morbo sacro*, to distinguish the veines from the arteries which are the conceptacles of the spirits calleth them αἱματίτιδας bloody, because they conuey the blood. The names of veines.

The latter Grecians haue included this name within narrower bounds and restrained it onely to quiet or still veines which haue but one simple coate, in whose footesteps we also doe insist calling the arteries not φλέβας but ἀρτηρίας, so the vessels beeing distinct their names also are distinct.

Furthermore, the vessels are distinguished in their structure, motion and vse. In the structure, because a veine hath a thin coate, whereas the coate of the artery is very thicke. In their motion, because an artery is mooued perpetually and conspicuously with a diastole and systole, that is, a dilation and contraction, whereas the veine is altogether immooueable. In vse because the artery transporteth the vitall spirit together with exceeding thin blood. The veines carry a thicker blood and a more cloudy spirit: the veins haue an inbred faculty to alter and boyle the blood; the arteries haue no such faculty, because their blood attaineth his vtmost elaboration and perfection in the heart. But let vs come to the definition of a veine. How veines & arteries differ.

A veine may be considered two manner of wayes, either as it is a Similar, or as it is an originall part. *Galen* in his 2. booke *de Elementis*, accounts it Similar, if not indeed, yet at least according to the iudgement of the sense; againe, in his boooke *de morborum differentiis*, he proueth that it is organical, for hee calleth veines arteries and muscles organs of the first kinde and most simple organs. Two considerations of a veine.

If you regard a veine as it is a Similar part, then must you define it by his temper, (for the temper is the forme of the similarity, that I may so speake) to be *A cold and drie part generated out of a slimy and following portion of the seed.* I sayde it was cold. In respect of his

his naturall temper for otherwiſe by the contaction of the blood and the perfuſion of the ſpirits it is very hot. And in *Galens* firſt booke *de temperamentis* It is ſayd to be hotter then the skin.

If you conſider a vein as it is an organicall part, then ſhall you define it to be *A veſſell long, round, excauated or hollowed like a reede hauing but one and that a thin coate wouen with all kindes of fibres, ariſing from the liuer and appointed or ſet a part by a Nature to contain boyle and diſtribute the blood.* In this definition you haue the figure, compoſition, originall, vſe and action of the organ elegantly deſcribed. The roundneſſe and cauity of the veſſel expreſſeth the figure of the organ whereby a veine is diſtinguiſhed from a nerue, for nerues haue onely pores but no ſenſible cauities. *Praxagoras* therefore was in an error and ſo are thoſe that follow him, who call nerues *venas continuatas* continued veines.

The explication of the definition.

The ſimple and thin coate noteth the ſtructure of the veſſell, and diſcriminateth or putteth a difference betwixt a veine and an artery, for an artery hath a double coate, one outward and another inward, and if we may beleeue *Erophilus* it is fiue-fold thicker then a veine, becauſe it containeth thinner and more ſpryghtfull blood, which if it were not concluded or ſhut vp within thicke wals would eaſily breake priſon and vaniſh away.

This ſimple coate hath fibres of all kindes, right, oblique and tranſuerſe, if not for his owne priuate nouriſhment, to which the attracting, retayning, and expelling faculties are ſeruiceable; yet for a common vſe to retayn and draw the blood which is the treaſure of Nature from the neighbour veynes to tranſmit the ſame from one to another and ſo to make diſtribution: finaly to ſeparate the pure from that which is impure. I thinke alſo ſayth *Laurentius* that the fibres were ordayned *ad ἐυρυθμίαν*, that is to auoyde an inconuenience, for becauſe oftentimes the blood aboundeth in quantity and offereth a kinde of violence to the veynes. Sometime by right, ſometime by oblique, ſometime by tranſuerſe extentions; he veynes ſtood in neede of all kindes of fibres, that they might bee ſo extended according to all the violent occurſions and impreſſions made by the blood, for otherwiſe they would certaynly be broken. Theſe fibres are the firſt moſt ſimple and truly ſolyd particles of the veine, but that ſubſtance which filleth vppe or ſtuffeth out the ſpaces betwixt the fibre. is called fleſhy by Analogy or proportion.

The fibres of the veyne ſayth *Galen* in his ſecond booke *de temperamentis*, are colder then the skin, but the fleſh that commeth betwixt them is hotter. Hence it appeareth, that the coate of the veyne differs much from the nature of other membranes, as of the *peritoneum* or rimme of the bell, the *pleura* which compaſſeth the ribs and the *periſteon* which immedyatly inueſteth the bones: for theſe are indeed ſimple hauing no ſeparated fibres, and may be borne or diuided euery way as paper may. But the coate of the veynes is diſſimilar becauſe it hath both fibres and fleſh.

The common coate of the veines.

This proper coate of the Veines is inueſted oftentimes with another called a *Common coate* which it borroweth from the neighbour partes, from the *Pleura* the Veines of the Cheſt doe borrow, and from the Rimme thoſe in the lower belly. I ſaid they haue often a Common coate, for all veines haue it not, for example, thoſe that are ſpinkled thorough ſome bowell, thoſe that wander through the bodies of Muſcles, and finally thoſe which are inſerted into the parts & in them are propagated or encreaſed: for ſuch a membrane would hinder the bloud that it ſhould not ſo readily ſweat through. Thoſe Veines onely haue this common coate, which either doe runne a long iourney, or lye vpon ſome hard body, or at ſome place are ſuſpēded or hung to any particular part: & ſuch is the ſtructure Veine.

The common vſe of the veines.

The beginning of the Veines the Definition ſayeth is the Liuer, not a beginning of generation or *original* (for that is the common worde though the firſt I thinke bee better) for all the parts are formed together, but of *Radication* and *Diſpenſation*. Of *Radication*, becauſe the roots of the gate and hollow veines are ſprinkled through the whole *Parenchyma* or fleſh of the Liuer according to that of *Hippocrates* in his Booke *de Alimento*, ῥίζωσις αἱμαβδῶν ἧπαρ *the Radication of the Veines is the Liuer*. Of *Diſpenſation*, that is, of diſtribution and office, becauſe from it a common matter, to wit the bloud which is the common Aliment of all the partes, is deriued into the Veines; wherefore by *Hippocrates* it is called ἰχμαλέον the fountaine and originall of pleaſant and benigne humour.

The laſt particle of the Definition deſigneth the common vſe and action of the Veines, for they are ſet a part to leade or tranſport, to diſtribute or apportion & to boyle the bloud. But why this is ſo and how it commeth to paſſe, I wil now addreſſe my ſelfe to declare.

CHAP

CHAP. II. *Of the Vse and Action of the Veines.*

BEcause the threefold substance which is in euery particular part flowing from the originals or principles of our generation, doth continually waste and suffer detriment; Nature who is studious of her owne conseruation by a perpetuall affluence of Aliment, laboureth to restore and make good that which is so necessarily spent and depopulated. The common Aliment of the parts is the blood, which all the Veines do draw from the Liuer as out of a common *magazine* or store-house. Now the blood could not be transported from the Liuer to those parts which are most distant and remote from it, vnlesse those parts had some continuity with the fountaine. The necessity of the veins.

It was therefore necessary that there should be made and formed certaine canals as it were water-pipes, bored to containe, conserue and conduct the blood throughout the whole body. Such are the Veines which *Aristotle* cals the vesselles or conceptacles of blood. The blood therefore is contayned in the veine as in his proper place, and as the Elemẽts in their proper places receiue no alteration; (for the place is the conseruer of the thing placed) so the blood within the veines retaineth his benigne nature, but out of the veines it presently either putrifieth or caketh. Their first vse

There is therefore in the Veines an inbred power to contayne and preserue the blood, which also is their primary vse. Another vse that the veines haue is to distribute the blood; which distribution is performed by an action. that is, by attraction or drawing from the neighbour veines, and by transmission or transportation vnto others, and for this action sake were the right and circular fibres of the veines ordayned. The second.

Hippocrates in his Booke *de Alimento* maketh mention of a third vse of the Veines, & that is to leade along heat and spirits into the particular parts. And thẽce it is that though the Arteries bee tyed the partes doe not presently *sphacelate* or mortifie, because by the veines there is an influence of a double heate and spirit, that is to say, Vitall and Naturall. The Vitall they receiue from the Heart by the wonderfull Anastomoses or innoculations of the Arteries; the Naturall they drawe directly from the Liuer. By this influent spirite the Inbred *Genius* of euery part is rouſed vp and quickned, and by it as by a good Mancible is the nourishment conuayed into the whole body. The third.

The last vse of the Veines which must bee referred also to their common action, is the alteration of the blood, for they are qualified to coyne and change the blood, some to prepare it as the Mesentery, others to perfect it as the great branches of the hollow veine. And this faculty or qualification they haue from the Liuer by *Irradiation*, as the Seminary vessels haue from the Testicles that power which they call σπερματοποιητικὴν. The fourth.

There are also other particular vses of priuate veines; as of the Emulgents to conuay the Serous or wheyie humor; of the seede vessels to giue a rudiment vnto seed: of the *Mesaraicks* to alter the *Chylus* and to transport it to the liuer; of the venall or short vessell to belch out melancholy iuyce into the cauity of the stomacke for the prouoking of appetite; of the veynes of the wombe to exclude the surplusage of blood at certaine and determinate periods, of the veynes of the splene to purge *faculent* or drosy blood, and so of the rest: for particulars we shall better handle in the following discourse. Peculiar vses of priuate veines.

Hippocrates the Oracle of Physicke from the habite and structure of the veynes, drewe many and those notable signs of the state of the whole body. Those that haue broade veines, sayth hee, haue also broade bellyes and broade bones, for, because the blood through the veines is diuided into the whole body, we may well make estimation of the plenty and temper of the bloode by the amplitude or straytnesse of the veynes. They that haue much blood are esteemed hot for their veynes are large. If the veynes be narrow and slender, *Aristotle* accounteth them cold. They that haue much flesh haue small veynes, red blood, and little bellyes and bowels: on the contrary, they that haue litle flesh haue large veynes, blacke blood, great bowels, and side wambes or bellyes. Finally by the veynes the whole body hath a kind of connexion or coherence, whence it is that they are called common ligaments.

CHAP.

CHAP. III. *The differences of veynes.*

THere are of the veynes innumerable & almost infinite surcles, yet al of them are saide to flow from fiue trunkes or bowes. For Anatomists doe account fiue especiall veynes. *The hollow veyne*, the *Gate veyne*, the *vmbilicall veine*, the *arteriall veine* and the *venall artery*. The *Cana* or hollow veyne is the largest of all the rest. It issueth out of the gibbous part of the Liuer, and is diuaricated or diuided into the stomacke, the spleene, the guts, and the *Omentum* or Kell. The vmbilical veine which is the Nurse of the infant runneth from the fissure or partition of the liuer vnto the Nauill, and whilest the infant is in the wombe it leadeth nourishment vnto it, but after the birth it looseth that vse altogether and degenerateth into a ligament. The arteriall veine hath both the name and office of a veyne, but is indeed an artery, and is all spent into the Lungs. The venall artery hath the coate and structure of a veyne, and might better be called a veine then an artery. The branches of this vessell are diuersly diuided and dispersed through the flesh of the whole Lungs. There are therefore fiue vessels commonly called veynes, which we (because we endeuour to deliuer nothing but truth) will referre to two: the *Hollow* and the *Gate* veynes. For the vmbilicall veyne is a propagation of the Gate veyne, and is so continuated thereto that I cannot perswade my selfe but it is a branch thereof. The venall artery is a shoote of the hollow veine, as may bee prooued by that wonderfull inoculation in the heart of the infant before the birth, of which we spake in the 25 question of the fift booke, and the 15 chapter of the 6. The arterial veyne hath his continuity with the great artery, by the *Arterial vessel* in those places mentioned, and may rather be saide to be an artery then a veine, because it hath a double and thick coate. There remain therfore but two notable veynes, the Hollow and the Gate veynes. The rootes of both these veynes are confusedly sprinkled through the flesh of the Liuer, yet so that there are many moe rootes of the Gate veyne in the hollow side of the liuer, and fewer in the gibbous or conuex: on the contrary, there are many moe rootes of the hollow veyne which runne through the gibbous part of the liuer, and fewer through the hollow part: so that it seemeth sanguification is made rather in the hollow of the liuer, distribution and perfection in the gibbous or embowed part. The rootes of these two vessels (which hath beene obserued but of late yeares) are wonderfully inoculated one with another, for the extremities or ends of the rootes of the Gate veyne are fastened into the middle of the rootes of the hollow veynes, and the ends of the hollow veyne into the middle of the rootes of the Gate veyne, that so the bloud might flow and reflow out of one into another of them. *Aristotle* therefore in his second booke *de partibus Animalium* saide true, (truer it may bee then hee wist, for haply hee had a Genius at his elbow) *that all the veynes were continuall*, yet *Hippocrates* before him hath the same thing in his booke *de locis in homine*; *All the veynes* saith he, *doe communicate and flow mutually one with and into another.*

Fiue vessels called veines.

Two veines onely.

Their inoculations.

Hippocrates.

And this saith *Lauren.* I haue somtimes proued to be true in childrē new born, for if you put a hollow bugle into the vmbilicall veine and blow it, you shal perceiue that the guts, the branches of the hollow veyne, the heart and the very flesh of the Lungs will be distended because the vmbilicall veine endeth into the Gate veine. Now in the parenchyma or flesh of the liuer there are many inoculations of the gate and hollow veines. The hollow veine also hath a continuity with the venall artery, which is the proper vessell of the Lungs by a large hole. This therefore shall be the first and most generall diuision of the veines.

Laurentius his obseruation.

The peculiar differences of veynes are taken from their magnitude, number, site, office, and the name of the parts to which they are deriued. In regard of the magnitude some are great, some middle, some small. Great and large veines *Hippocrates* calleth κοίλας καὶ αἱμόῤῥυς hollow and sanguifluent because they yeelde aboundance of bloud if they be eyther wounded, or broken, or opened. The lesser veynes are called *Capillares*, hairy or threddy veines, because when they be diuided they yeeld, but slender and small streames of blood, and are easily stanched. Those parts that neede abonndance of nourishment or which are moued continually haue greater veynes. So the Lungs haue notable vessels, so the flesh and all hot and moyst parts haue great veynes; but bones, gristles, & ligaments very small veines.

The peculiar difference of veynes from the magnitude.

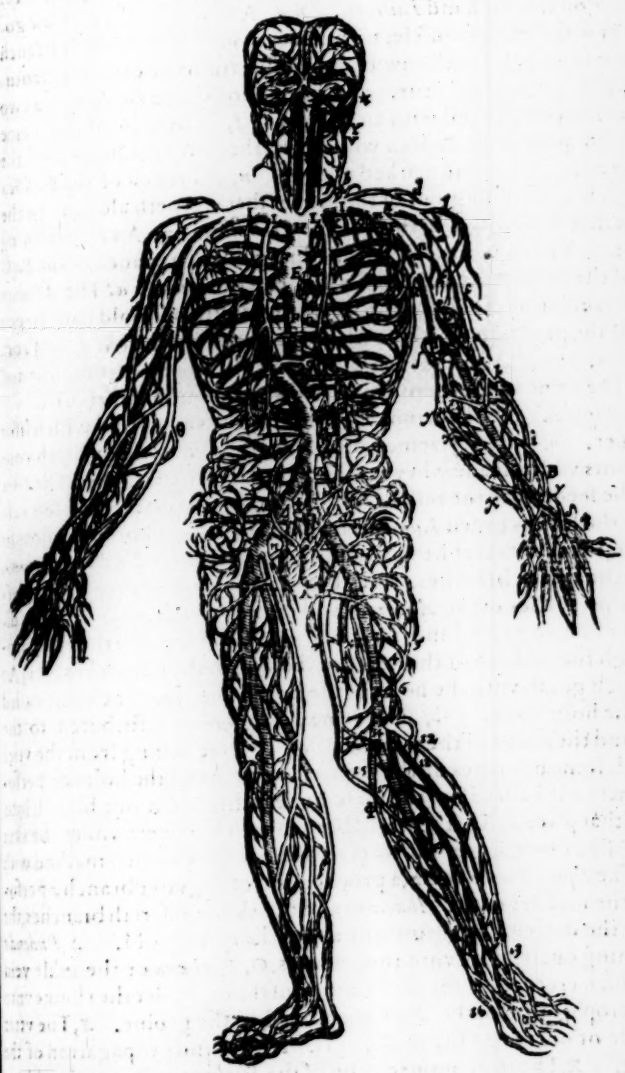
From the number; some veynes are without companions, as that in the Chest called

Number.

Azygos,

Table 1. Sheweth the hollow veine, whole and freed from the whole Body.

TABVLA I.



A, The trunke of the hollow veine.

the lower A A, At this place of the Liuer, is seated the left part of the veyne, and distributeth branches to the left side.

B, Sheweth how the trunke of the hollow veine in the chest, to giue way to the heart, is curued or bowed to the right hand.

Betwixt A and B; that part of the hollow veine which is betwixt the gibbous side of the Liuer and the Midriffe.

C, the left midriffe veine called *Phrenica sinistra*, from which surcles doe run in a man vnto the pursse of the heart, for the midriffe and it do grow together.

D, the orifice of the hollow veine which groweth vnto the heart.

E, the crown-veine called *coronaria*, which like a crowne compasseth the basis of the heart, and sprinkleth his surcles on the outside thereof as farre as to the cone or point.

F F, the trunke of the veine, *Azygos* or *non parill* descending along the right side of the racke-bones vnto the loynes.

G G, the lower intercostall veines, or the branches of the veine *Azygos*, which go vnto the distances betwixt the ribs, and affoord surcles vnto the muscles which lye vppon the ribs and the racke-bones, and the membranes of the chest.

H, the diuision of the hollow veine into 2 subclauian trunkes neare the Iugulum vnder the breast-bone.

I I, the subclauian branch tending on eyther side vnto the arme, called by some *Axillaris*.

K, the vpper intercostall veine which commonly sendeth three slips vnto the distances of the vpper ribs, vnto which the first intercostall veine sent no branches.

L L, the descending mammary veine: this descendeth vnder the breit-bone vnto the right muscles of the *Abdomen*, and affoordeth surcles to the distances of the gristles of the true ribs, to the Mediastinum, the muscles that lye vppon the breast and the skinne of the *Abdomen*. M, the coniunction of the mammary with the Epigastricke veine ascending about the Nauill vnder the right muscles. N, the veine of the necke called *Cernicalis*, ascending toward the Scull which alloweth surcles to those muscles that lye vppon the necke. O, the veine called *Musculs*, which is propagated with many surcles into the muscles that occupy the lower parts of the necke and the vpper parts of the chest. P, *Thoracica* superior, the vpper chest veyne which goeth to the muscles lying vpyon the chest, to the skinne of that place and to the dugges. Q, the double *Scapularis* distributed into the hollow part of the shoulder-blade and the neighbour muscles: so also betwixt *P* and R, sometimes small veines do reach vnto the glandules that are in the arme-holes. R, *Thoracica inferior* running downeward along the sides of the chest, & especially distributed into the muscle of the arme called *Latissimus*. S, the inner Iugular veine which entreth into the Scull after it hath bestowed some surcles vppon the rough artery. T, the externall Iugular veine. V. The diuision of this veine vnder the roote of the eare. X. A branch of the externall Iugular which goeth into the inside of the mouth, and is diuersly diuided into the parts therein contained. Y, the exterior branch distributed neare the *Fauces* into the muscles of the chops and the whole skin of the head. Z, A portion of the branch, y, reaching vnto the Face. *a a* the veyne of the fore-head, *a*, A portion of it creeping through the temples *a*. * A propagation that goeth vnto the skinne of the Nowle or *Occiput*. *a a* The veine called *Cephalica*, or the externall veyne of the arme which others call *Humeraria*. *b Musculs superior*, A propagation of the *Cephalica* veyne which goeth vnto the backward muscles of the neck. Betwixt *c* and *d* on the backeside issueth a branch from the *Cephalica* which passeth vnto the outside of the blade, and a portion thereof runneth betwixt the flesh and the skinne. *d d* A veyne from the *Cephalica* which attaineth vnto the top of the shoulder, and is consume d into the muscle that eleuateth or lifteth vp the arme & into his skinne. *e e* A small veine from the *Cephalica* disperssed through the skinne and the muscles of the

arme. *f*, The diuision of the *Cephalica* into three parts. *g*, The first branch runneth deepe vnto the muscles which arise out of the externall protuberation of the arme. *h* The second branch which goeth to make the *median* veine. *i*, The third branch running obliquely aboue the wand and the outside of the arme. *k*, From this branch certaine surcles are diuided into the skin, the chiefe whereof is marked with *k*. *l*, The third branch at the wrist which is ioyned at *l*, with the branch of the *Basilica* marked with *x*. *m*, The *Basilica* which or the right hand is called *Hepatica*, on the left hand *Lienaris*. *n*, *o*, A branch of the *Basilica* going to the heads of the muscles of the cubit at *n*, and to the muscles themselues at *o*. *p*, A notable branch of the *Basilica* running obliquely, and bestowing surcles to the muscles that issue from the externall protuberation. This branch descendeth together with the fourth nerue. *q*, The diuision of the *Basilica* into two branches, and that that is noted with *q*, is euer accompanyed with an arterie. *s*, A branch of this veine bestowed vppon the skin of the arme. *t* A branch of the *Basilica* which together with the branch of the *Cephalica* marked with *h*, makes the *mediana* or middle veine marked with *a*. *u*, A branch of the *Basilica* going to the inner head of the arme. *x x*, A branch issuing out of the former that creepeth along vnto the wrest and toward the little finger conioyneth it selfe with a branch of the *Cephalica*. *y*, A veine running out vnto the skin at the outside of the cubit. Vpper *z*, a propagation issuing out of a branch of the *Basilica* marked with *t*. Lower *z*, A branch of the *Basilica x*, going to the inside of the arme. *α*, The *Median* or common veine. *β*, The partition of the median veine aboue the wrest, this diuision should haue beene made aboue *γ*. *γ*, The externall branch of the partition which goeth to the outside of the hand. *δ*, From which issueth a small branch to the inside. *ε*, The internall branch vnder *ε*, which toward the middle and the ring finger is especially disposed. *ζ*, The veine of the thumb dispersed into his mountenet or hillock which is conioyned with the branch noted wieh *δ*. *ζ*, The trunke of the hollow veine from which issue branches vnto the parts seated vnder the liuer. *η*, The fatty veine called *Adiposa sinistra* which goeth vnto the fat of the kidnies. *θ ι*, The two Emulgents which leade wheyey blood vnto the kidnies. *κ μ*, The two spermaticall veines leading the matter of the seede vnto the testicles. V, The beginning of the bodden vessell called *vas varicosum*. *ξ*, The veines of the loynes called *Lumbares* which are sent in knots or knees to the rackebones, to the marrow of the backe, to muscles that lie vppon the loynes, and to the *Peritonæum*. *ο*, The bifurcation of the hollow veine into the Illiack branches, which bifurcation is not vnlike *λ*. *π*, *Musculasuperior*, a transuerse branch going to the muscles of the *Abdomen* and to the *Peritonæum*. *ρ σ*, The diuision of the left Illiacke veine into an inner branch a *ρ*, and an vtter at *σ*. *τ*, *Musculamedia* the vtter propagation of the branch *ρ* distributed through the muscles of the *coxa* and the skin of the buttockes. *υ*, An inner propagation of the same branch *ρ* which goeth vnto the holes of the holy bone. *φ*, The veine called *Sacra* which goeth to the vpper holes of the holy bone. *χ ϟ*, The veine *Hypogastrica* distributed to the bladder, to the muscles of the fundament, and the necke of the wombe. *ω*, A veine arising from the vtter branch marked with *σ* which is ioyned with some branches of the internall veine, neare the holes or perforations of the share bone. *ա*, A veyn which when it hath passed the share bone distirbuteth one branch into the cup of the *coxendix* & to the muscles of that place. *א*, Another small branch which runneth vnder the skin at the inside of the thigh. *χ*, The congresse or meeting of the foresaid veine with a branch marked with char. 2, and distributed into the leg. *ר*, The *Epigastricke* veine, a propagation of the vtter branch *σ* perforating the *Peritonæum*, whereto as also to the muscles of the *Abdomen* and the skin it offereth branches, the chiefe branch of this veine is ioyned with the descending mammarie about the nauell at M. *Δ*, *Pudenda* an inner propagation of the branch *σ*, running ouerthwart vnto the priuities. *Θ*, *Saphæna* or the ankle vein or the inner branch of the crurall trunke, which creepeth through the inside of the leg vnder the skinne vnto the tops of the toes. *Λ*, The first interior propagation of the *Saphæna* offered to the groine. *Ξ*, The vtter propagation thereof diuided to the foreside or outside of the thigh. *Π*. The second propagation of the *Saphæna* going to the first muscle of the leg. *Σ*, The third propagation of the *Saphæna* going to the skinne of the whirlebone, and vnto the Hamme. *Φ*, The fourth propagation of the *Saphæna* dispersing his surcles forward and backeward. *Ψ*, Branches from this vnto the foreside of the inner ankle, to the vpper part of the foote, and to all the toes. *Ω*, *Ischias minor* called also *musculainterior*, the vtter branch of the crurall trunk diuided into the muscles of the *coxendix*, and to the skin of that place. 1, 2, And this also may be called *musculus*. 1, the exterior and lesser which passeth into some muscles of the leg: 2, the interior greater and deeper vnto the muscles of the thigh. 3, 4, The veine called *Poplitea*, made of two crurall veines diuided vnder the knee. 5, From this a surcle is reached vpward vnto the skinne of the thigh. 6, But the greater part runs by the bent of the knee vnder the skinne as farre as to the heele. 7, Also to the skin of the outward ankle. 8, The veine called *Suralis* or calfe veine, because it runneth vnto the muscles that make the calfe of the leg. 9, The diuision of the Surall veine into an exterior trunk 9 and an interior 14. 10 11, The diuision of the exterior trunke vnder the knee into an externall branch, which along the brace attayneth vnto the muscles of the foot 11, and in internall, 12, 13. 12, 13, Which descending a long the outside of the legge to the vpper part of the fotte is clouen into diuers branches, and in the backe of the foote mixeth it selfe with *Poplitea*, or hamme veine 20. 14, The interior branch of the Surall veine which runneth into the backeside of the leg. 15, A branch hereof descending to the inside of the heele and the great toe and is diuided into diuers surcles. 17, *Ischias maior* issuing out of the internall trunke at 14, and running through the muscles of the calfe. 18. A propagation hereof deriued vnto the vpper part of the foot, and affording two surcles to euery toe. 19, The remainder of the inner trunke 14, behinde the inner ankle, approcheth to the bottome of the foote and is consumed into all the toes. 20. the commixtion of the Veine *Poplitea* with the surall or Calfe-branch at 13,

are

Azygos or the *nomparell.* Others haue companions, as almost all the rest. Others agine are solitary, that is, haue no artery accompanying them, as the veine of the arme which is called *Humeraria*, others haue arteries bearing them company.

This by the way we must obserue, that the veines are more and greater then the arteries, because they containe a thicker Aliment and more cloudy spirit,

From the situation a veine is sayd to bee vpper and lower, ascendent, descendent; right, left; externall, internall, so the splenicke branch is called *sinister* the left, the mesentericke *dexter* the right. So *Hyppocrates* in his booke *de victus ratione in acutis*, calleth the *Basilica venam internam*, the internall veine, because it runneth through the inside of the cubit, and the *Humeraria* he calleth *externam*, because it runneth on the outside.

In respect of their office or function, some veines are called *Emulgentes* the suckers because they sucke and separate wheyie humours; others *spermaticæ*, because they giue the seede a rudiment.

In respect of the parts through which they run, the veins haue diuers names, *Iugulares*, *Phrenicæ*, *Renales*, *Iliacæ*, *Hypogastricæ*, *Epigastricæ*, *Axillares*, *Humeraria*, *Crurales*, *Poplitea*, *Malleoli*, &c. because they run through the sticking place, the midriffe, the kidneyes, the hanches, the watercourse, the lower belly, the arme pits, the armes, the legs, the hammes and the ankles.

But because you might haue, as it were, in one view all the veines of the body, to know their deriuations, we haue to this chapter annexed a table which exhibiteth the course of the hollow veine from the crown of the head to the soale of the foote, and the description adioyned thereto, which wil poynt out euery particular. As for the skin veines how they appeare on the surface of the whole body, you haue also a general view of them in the eight chapter of the second booke, and therefore we will not repeate their Tables in this place, but descend vnto the particular hystory, beginning with the gate veine.

CHAP. IIII. *The description of the Gate veine and his branches.*

I Gaue you (because the order of dissection so required) a briefe compend of the distribution of the Gate veine in the third chapter of the third booke, reseruing there the more exact discourse vnto this place, which therefore we will now attend as carefully as we may.

That which they call the Gate veine [Tab. 2.] some thinke is a propagation from the vmbilicall veine, to which as we sayde it is continued. It issueth out of the hollow part of the liuer, which part or rather the very ingresse of the vessell (betwixt the 2. small Eminencies of the liuer) *Hippocrates* and *Galen* and the whole family of the *Asclepiads* doe call πύλας the *Gate*. It is the greatest of all the veines next the hollow veine, and therefore *Galen* in the twentyeth chapter of his fourth booke *de vsu partium* calleth it μεγάλην, or the great veine. The hollow veine he calleth μεγίστην, or the greatest veine, but commonly he cals it *the veine which is at the Gate*, because by the roots hereof, that is to say, the Mesaraicke branches the *Chylus* is suckt away from the stomacke and the guts, and through the trunke hereof as through an open gate is let into the liuer. Whereupon the *Mesaraicks* are called *manus hepatis*, *the hand of the liuer*. The Physitions call it commonly *vena portæ*, the gatevein; the Arabians *venam lacteam*, or the milky vein, because it draweth the *Chilus* which is like vnto milke. The names of the gate vein and the reason thereof.

For order sake we will diuide this Gate veine into rootes, branches, and the trunke it self. The roots are small and aboundant, desseminated [tab. 2. ch. 1, 2, 3, 4, 5.] through the substance of the liuer from whence as from a principle of distribution (saith *Galen* in the fourth chapter of his booke *de formatione fœtus*, and in the third of the seuenth *de placitis*) and of Radication (saith *Hippocrates* in his booke *de Alimento*) they doe arise. These small rootes by degrees grow into greater, and those yet into greater, till all of them about the middle of the liuer on his hollow side neare vnto the backe are vnited, and make one notable trunke [Tab. 2. B.] which issueth out of the liuer. These rootes whilest they remaine in the liuer, are ioyned by inoculation into the middle of the rootes of the hollow veine as wee haue shewed in the thirteenth chapter of the third booke and the fourteenth table. The diuision the gate vein

In dogs there are so many bowes of the gate veine as there be lobes of the liuer, euery one of which is diuided into his owne lobe, and yet all of them meete into one common trunke. Notwithstanding they may be called Rootes and Branches. Rootes, be-

cauſe this veine is ſayd to be the ſprout of the Liuer, and becauſe they leade blood vnto other parts. They may alſo bee called braunches becauſe the meſaraicks (which *Galen* likening it to a tree, calleth the Rootes) when they haue ſuckt the Chylus doe ſend it vnto the Trunke, from whence by theſe branches it is diſtributed into the Liuer.

Sometimes from the rootes of the Gate-veine from the very top of the left part of Liuer neare his Ligament, yſſueth a braunch which is communicated to the Midriſſe, and deſcending on the backeſide is ioyned vnder the *Pancreas* or Sweete-breade with other braunches which ariſe out of the trunke of the gate-veine. Sometime alſo a few branches ariſing out of the ſame place doe attaine vnto the Spleene and are diſſeminated into his ſubſtance.

The trunke. The trunke [Table 2.B] deſcending from the Liuer runneth a little obliquely downeward vnder the Gutte called *Duodenum*, hauing gotten a firme ſeate aboue the Rackebones.

It maketh his diſtribution betwixt the Stomacke and the Guts as in the fitteſt place, becauſe it is the middeſt of the organs of nouriſhment where it was fit that diſtribution ſhould be, that the veines might be equally deuided amongſt them. For if it had deſcended lower it had departed too farre from the Stomacke. If it had aſcended higher, firſt it would haue beene too far from the Guts; and againe, could not haue had ſo eaſie acceſſe vnto the ſtomacke, which ſometimes ſtrutteth with aboundance, and againe falleth when it is empty. From this Trunke therefore diuers propagations are diſtributed in the lower belly into the Stomacke, the Guts, the Kell and the Spleene.

Where deuided & why.

The trunke. The Trunke [Ta.2.B] before it is deuided parteth with two ſmall braunches from his foreſide. The firſt are called *Cyſtica Gemela* the Twinne-veines of the Gall [Tab.2.C C] which yſſuing from toward the left ſide of the trunk are reflected vpward and toward the right ſide vnto the neck of the bladder of Gall and the body thereof, through which they are diſtributed in hayrie braunches as are the ſmall veſſels through the white of the Eye.

Cyſtica Gemela

Gaſtrica dextra The ſecond is called *Gaſtrica dextra* [Ta.2.D] the right ſtomacke veine. It ariſeth much lower then the twins and rather from the right ſide of the Trunke on which ſide it paſſeth onely vnto the backepart of the ſtomack and the *Pylorus* or lower mouth thereof, and affordeth them ſmall branches.

Afterward the Trunke inclining to the left hand is deuided into two notable bowes [Ta.2.E] the vpper or the left, and the lower or the right. The vpper [Ta.2.F] although it be altogether ſpent into the Stomacke and the Kell; yet from the vſe it is called *Splenicus* or the Spleene-braunch, becauſe it draweth to it ſelfe out of the *Chylus* altered in the *Meſeraicke* veines the thick part of the iuyce before it be gotten to the Liuer, and leadeth it to the Spleene as we haue ſayde before in the Hiſtory of the Spleene, wherefore alſo it is placed aboue the trunke of the Meſeraicks. [Ta.2.G] The lower bow is called *Meſentericus* the meſentericall braunch [Ta.2.G] becauſe almoſt all of it is diuided into the Meſenterie.

Ramus ſplenicus

Meſentericus.

The Splenicke braunch being ſupported with the Membrane of the Kell and a glandulous body, runneth ouerthwart to the Spleene, and before it bee conſumed thereinto, there proceede braunches out of it, ſome before ſome after the deuiſion. Before the diuiſion ſome yſſue from the vpper part ſome from the lower. From the vpper part two veines ſpring.

Gaſtrica minor. The firſt is called *Gaſtrica minor* the leſſer Stomacke veine, and [Table 2.K] the left is deuided into the gibbous and backepart of the ſtomacke with a few branches.

Gaſtrica maior. The ſecond is called *Gaſtrica maior* [tab.2.N] the greate ſtomacke veine, becauſe it is the largeſt of all the veines that come vnto the ſtomacke. It runneth obliquely vnder the Stomack to his vpper orifice or mouth, & is deuided thereinto, ſending out of the trunke three boughes; of which, one on either ſide is conuayed to the Stomacke, [Ta.2.OO] the middle runneth vpward and compaſſeth the vpper mouth of the ſtomacke like a crowne, and maketh that veine which thereuppon they call *Coronariam ſtomachicam* the Crowne veine of the ſtomacke, [tab.2.Q] which in dogges is very conſpicuous. From this veine ſome ſmall ones are offered vpward vnto the end of the Gullet, ſome downeward to the Stomacke.

Coronaria ſtom.

Sometimes alſo another braunch ariſing from the other propagation runneth downward, and on the foreſide paſſeth the *Pylorus* or lower mouth of the ſtomacke with many Surcles. From the lower part yſſue three branches.

The

The first is called *Epiplois dextra* [Ta.2.L] the *right Kell veine.* It is but a slender vessell, and deriueth his Surcles downeward to the right side of the lower membrane of the Kell, and to the Collicke Gut which is thereto annexed. *Epiplois dextra.*

The second is called *Epiplois postica* [Tab.2.S] the *hinder Kell veine.* It is larger then the former and is deuided into 2. branches which are very much separated, out of which surcles doe runne downeward to the lower membrane of the Kell, (wherewith the Collicke Gut is tyed to the backe as it were with a Mesentery) and to some part also of the *Colon* it selfe. In Dogges there is no veine from the spleenicke braunch vnto the Collicke Gut. *Epiplois postica.*

The third called *Pancreæ* [Table 2.M] are many small and capillary veines which run betwixt the two Kell veines as well aboue as below, and are disseminated into the Sweetbread which is called *Pancreas* from whence they haue their name. *Pancreæ.*

When these branches are produced, the Splenicke [tab.2.F] Trunke is cleft into an vpper and a lower brance, [ta.2.T] and these into others.

From the vpper braunch doe arise sometimes three, sometimes more, sometimes one from the top of the branch neare the Spleene which they call *Vas breue* [Ta.2. the vpper Z] or *Vas venosũ*, the *Short* or the *Venall vessell*, which is in some men greater, in some men lesser, and these latter doe easily indure hunger, the former with great difficulty. And hence it is that some men if they bee neuer so little a while without meate, or betweene their refections they fall into a *Syncope* or swounding; by this braunch also come oftentimes blacke vomits. *Vas breue.*

[*Table 2. is the same with Table 3. lib. 3. Folio* 100]

These Veines being sustayned with the vpper membrane of the Kell, are inserted into the left side of the bottome of the Stomacke, and sometime higher that they might belch that naturall melancholly bloud which could not bee chaunged into the Aliment of the Spleene, into the bottome of the stomacke sometimes into his mouth (which *Vessalius* witnesseth that he hath seene) to stirre vp the drowsie appetite with his tartnesse, before the mouth of the stomacke be corrugated for too much want, for that sowre thinges doe prouoke appetite, we are taught by the sharpe Sallets that are vsed in the beginning of our Suppers. Beside the adstriction or binding property of this humour strengthneth the mouth and helpeth the concoction of the body of the stomack. Sometime also from another propagation of this braunch, veines are transmitted to the stomacke, and these tye the stomacke and the Spleene fast together.

From the lower braunch of the Splenicke bough proceede two veines. The first is called *Epiplois sinistra* or the *Left Kell veine* [Ta.2.V] which in one or two surcles is distributed into the left part of the lower membrane of the *Omentum* or Kell, especially when the hinder Kell veine is narrow, wherefore this veine is not alwayes found. *Epiplois sinistra*

The second is called *Gastro-epiplois sinistra* [Ta.2.X] the left Stomacke and Kell veine. It is a notable braunch, and reflected to the right hand compasseth on that side the bottome of the stomack where the smal branches of this veine are intangled with the slender surcles of the right, and touch either the others extremities. It affordeth also small branches, but very plentifull to the left side of the vpper membrane of the *Omentum.* *Gastro epiplois sinistra.*

The remaynder of both braunches being diuersly wouen together, are implanted in great aboundance [Ta.2.YZ] into the hollow and middle line of the Spleen, and are distributed through his whole body to purge the fœculent iuyce, & to lead it to the spleen, and thus much of the left or vpper branch of the gate-veine.

From the lower and Right branch [Ta.2.G] which is also the larger, before it be deuided, two veines do yssue.

The first is called *Gastro-epiplois dextra* [Ta.2.H] the *right Stomacke or Kell veine.* It yssueth from the side of the braunch before it be deuided into the mesenterical branches. Sometime it ariseth out of the Trunke it selfe, sometimes also but very rarely out of the left braunch, and on the right side watereth the bottome of the stomack both before and behind with many small surcles which insinuate themselues euen into his cauity. It creepeth also through the vpper membrane of the Kell, and at the middle of the stomacke it ioyneth his small surcles with the left *stomacke and kell veine.* [Ta.2.X] In Dogges sometime it yssueth from the Gut-veine. Sometime it is wanting and then the left supplyeth the place of both. Brãches from the right bow of the gate-veine. *Gastro-epiplois dextra.*

Inteſtinalis. The ſecond is called *Inteſtinalis*, [Tab.2, I] or the gut-veyne. It iſſueth ſometimes out of the branch, ſometimes out of the trunke at the middle of the *Duodenum* or the beginning of the *Ieiunum*, and running directly downeward through their length, it diſperſeth certain ſmall branches as fine as hayres through the vpper *Omentum* and through the *Pancreas*.

Afterward the whole branch [Tab.2,ᵉ] where it ioyneth with the meſentery, departeth into three meſentericall branches, two on the right hand and two on the left.

The right meſentericall branch is double, [Tab.26,] and is implanted into the *Ieiunum*, the *Illion*, the *Cæcum*, and the right part of the Colon on the backe or hollow ſide, and being diuided into inumerable ſurcles, as the rootes of a Tree are diuided into ſlender ſtrings (whereto alſo *Galen* compareth theſe) they make the meſeraicke veines [Tab.2. dddd] which run obliquely betwixt the two membranes of the meſentery, and amongſt which there are many ſmall glandules placed to ſerue their paſſage and determine in the Guts; not into their cauity, for that is compaſſed about with a cruſt, but their little mouths do open into the coate of the gut, from whence they ſucke the Chylus as the tendrils of a roote ſucke the Iuice out of the earth. Wherefore in the guts called *Ieiunum* and *Ileon* they are more aboundant, becauſe they contain a greater quantity of Iuice then the great guts doe.

The meſeraicke veynes

But they were not onely created to leade away this Iuice, but alſo to attract it and prepare it for the Liuer, after a manner, ſaith *Galen*, moſt like vnto it ſelfe, becauſe their nature is alike, and they draw their firſt originall therefrom; wherefore after they haue giuen vnto it the beginning or rude forme of blood, and out of them and from the blood the thicker part is drawne by the Spleene through the ſplenicke branch, [Tab.2,F] they lead it vnto the Liuer. For as Porters doe carry the dreſſed Corne into the Garner or common Store-houſe of a Citty where it is prepared for nouriſhment, ſo the meſeraick veines doe conuey the aliment laboured in the ſtomacke to the common place of the creatures concoction, that is, vnto the Liuer, not to poure it into his ſubſtance there to be changed into blood, but to be reſerued and laboured in the rootes of the Gate-veine, which are moſt what on the inſide and hollow part of the Liuer, for vnto theſe rootes the Liuer giueth the power of ſangufication as we haue ſaide before in the tenth Chapter of the third booke.

The double worke of the meſeraicks.

Moreouer, the ſame meſeraicks by which the diſtribution is made of the Chylus from the guts to the Liuer, do alſo carry blood from the Liuer to the nouriſhment of the guts, yet not at the ſame time, but when they are empty and want nouriſhment, and if it happen that both workes concurre together, which *Galen* yeeldeth to bee ſo in the ninteenth chapter of his fourth booke *de vſu partium*, then according to the diuers nature, deſire, & ſtrength of the drawing parts, the veynes of the Liuer ſnatch the Chylus and the guttes blood. For if you make Iron and Strawes in powder together and mingle them, heated Amber will draw away the ſtrawes, and a Load-ſtone wil draw away the Iron by reaſon of their diuers natures and diuers deſires of attraction.

Why there be no values at their ends. Againſt *Columbus*.

Now this double attraction could not be performed if the extreame orifices of the veines had values ſet vnto them as *Columbus* dreamed, but *Archangelus* refuteth by many arguments, who ſaith *Columbus* was deceiued by that cruſt which is ingendered of the excrements of the third concoction, and compaſſeth the guts no otherwiſe then the Scarſe-skinne cloſeth the extremities or ends of the cutany veynes.

Beſide, if there were any ſuch values they would hinder the confluence of the humors from the whole body into the guttes, which is made eyther by the want of Nature or of medicine, for ſaith *Galen* 3 naturall: facult: the purgations of the whole body are made by the meſeraick veynes, eſpecially by the lower of them, and ſo much of the right meſentericke branch.

The left meſenrericke.

The left meſentericke veyne [Tab.2,ᶜ] is diſſeminated into the left and middle part of the meſentery, and attaineth that Region of the collicke gut, [Tab.2,ᶜᶜ] which reacheth from the eſt ſide of the ſtomack euen vnto the right gut.

The internall Hemrod-veynes.

From this deſcendeth a notable branch called *Hæmorrhoidalis interna*, [Tab.2,ᵍᵍ] *the inward emrod veyne* (for the externall proceedeth from the hyppogaſtricall branch of the hollow veyne) and it runneth by the end of the collicke gut vnder the right gut, [Tab. 2,ᶠᶠ] whoſe extremity (which they call the Fundament) it compaſſeth about with a fewe ſmall ſurcles, by which expurgation is made oftentimes in obſtructions of the ſpleene, of

fœculent

fœculent blood when it is too aboundant, and that in many bodies at certaine and determinate times.

This veyne taketh his originall sometimes from the splenicke branch, from which also the Short or Venall vessell issueth: and thus much concerning the branches of the Gate-veine.

Now the difference betwixt the Gate and the Hollow veynes is, that the Gate-veyne is more lax and soft, the Hollow-veyne faster and harder, because the Gate veyne serues rather from attraction then for expulsion, for by it the spleene and the Liuer draw more then they do expell. The diference betwixt the Gate and the hollow veyne.

On the contrary, the gate veine serueth rather for expulsion then for attraction, for by it the blood is expelled into the whole body although it is not a little assisted by the attraction of the members.

The vse of the gate-veyne is to distribute branches which may eyther serue for nourishment as those that leade blood into the naturall parts destituted and forsaken by the hollow veyne, or for the expurgation of some excrement as the splenicke branch which draweth vnto it selfe out of the trunke of the gate-veyne, before the Chylus attaine to the Liuer, a thicke and fœculent humor yet mingled with much laudable Iuice, and the *vas Breue* and the *Hemorrhoid-veyne*. Other branches make for the distribution of the Chylus into the gate of the Liuer, in which also it receiueth an alteration & preparation of blood as the meseraicks and those veynes which we saide attained vnto the stomacke to draw a part of the Chylus euen from thence. The vse of the gate-veyne and of his branches.

Finally, others perfect the blood as those small veynes disseminated through the flesh of the Liuer, which we called the rootes of the Gate-veyne.

Note moreouer that all the gate-veyne lyeth within the body, neuer attaining vnto the skinne, and therefore his branches are not opened vnlesse haply about the fundament, where they make the Emrods, (to which we do more often apply *Horsse-leaches*) and in women at the necke of the wombe: and so much of the Gate-veyne. Note.

CHAP. V. *Of the descending trunke of the hollow veine.*

THE hollow veine called *cana*, because of his large cauity, is by the Grecians called κοιλὴ and μεγάλη the great veine, *Galen* sometimes, as in the fifth chapter of his fourth booke *de vsu partium* calleth it μεγίστη, the greatest veine. *Hippocrates* callet it ἐπατικὴν *Iecorariam* the liuer veine. The name of the hollow veyne. His beginning This is the common mother of all the veines, except the vmbilicall and the gate veines. It hath one beginning of *Originall*, that is, the seede, for it is made at the same time with the other spermaticall parts which are made or generated together, though some of them bee perfected and absolued before others.

Another beginning it hath of *dispensation* and *radication*, and that is, the Liuer, and therefore it is said to issue out of the gibbous part of the Liuer, where his substance is greter and thicker. For although the orifice of the hollow veine at the right ventricle of the heart be much larger then his capacity is in any other place; yet it doth not thence folow that it must arise from that right ventricle as *Aristotle* imagined, and after him *Vesalius* rather to carpe at *Galen* then that he was mooued thereto by any waighty reason. Whereof it is made.

For the making and framing of this hollow veine, [tab. 3. fig. 2. and 3. and Tab. 4. shew it,] out of the vtmost circumference of the Liuer in the gibbous part thereof, [Tab. 2. fig. 2. C C.] do arise innumerable propagations of small veines [tab. 3. fig. 4. C C c. Ta. 4. E E EE. [which creeping by degrees toward the middle of the backside of the liuer, [tab. 4. C. C.] doe meete together, or vnite themselues into larger veines, & these againe into greater, till at length they all passe in the vpper part of the liuer where it regardeth the right side of the backe into two very notable branches [tab. 3. fig. 3. M, N.] the one dispersed into the right, the other into the left part of the Liuer: both which doe determine into one stalke,] Tab. 3. fig. 2. F. fig. 4. A. tab 4.] which is called cõmonly *the trunke of the hollow veine*. VVherefore this trunke applyeth it selfe, or inclineth from the right side of the liuer to the backe side where it entreth, as it were into a *sinus* or cauity, and with a short passage groweth to his substance.

This trunke is seated according to the length of the backe, and runs with a streight course throgh both bellyes that so it might conuay vnto the whole length of the creatures blood (which

Table 3 is the same with Table 13 Lib. 3 folio 130

(which is the common Aliment of all the parts) laboured in the Liuer in the rootes [Tab. 3, fig. 4. F F, tab. 4 K K K K] of the Gate-veyne; which rootes are implicated or intangled with the rootes of the hollow veyne, [Tab. 3, fig. 4, C C, Tab. 4, E E E E] disperſed confuſedly through the fleſh of the Liuer touching one another in many places ouerthwart, [ta. 3, fig. 4, and tab. 4 ſhew this.] Many rootes alſo of the Gate-veyne do infix or faſten their extremities or terminations into the middle of the rootes of the hollow veyne, [tab. 3, fig. 4, G G G G Ta. 4, L LL] as on the contrary many ends of the rootes of the hollow veine are faſtened into the middle of the rootes of the gate-veine. By which Anaſtomoſes or inoculations the blood is tranſmitted out of one veyne into another, and ſo conueyed into the whole body. For the hollow veyne is like a water-pipe full of blood which hath many riuerets ſome greater and ſome leſſe iſſuing therefrom and diſtributed into all the parts. For Nature in this adminiſtration is not onely very prouident but alſo equall & indifferent, and therefore diuideth this veyne into many ſmall parts, that each mẽber might haue his due proportion, that is to ſay, Aliment anſwerable to the ſubſtance that waſteth away. So hot and ſoft parts and thoſe that are much exerciſed do ſuffer great expence as the Lungs, and therefore their veyne is very large: but colder and harder parts which are moderately exerciſed, are not ſo eaſily diſſolued, as the bones which therefore haue very ſmall & ſlender veines. Betwixt theſe are all the other parts whereof ſome haue more euacuation and ſome leſſe, and therefore they want more or leſſe nouriſhment.

The inoculations of the gate and hollow veine.

Table 4 is the ſame with Table 14. Lib. 3 folio 132.

The hollow veyne for order ſake, and perſpicuity we diuide into an vpper trunk [ta. 3, fig. 3, [p] fig. 4, [A] ta. 4, aboue [A]] and a lower, [ta. 3, fig. 2, at [c] fig. 4, [B] ta. 4, [DD]] the vpper piercing through the midriffe and climing vpward diſtributeth very many branches into al the ſupior parts, of which we ſhall ſpeake in the next chapter.

The deſcending trunke [ta. 5, [x]] is leſſer then that which aſcendeth, becauſe the vpper parts do require more blood; for that many parts in the lower belly contained receiue branches frõ the Gate-veine. It adhereth on the right hand to the bodies of the rackbones (for on the left ſide [ta. 5, [L]] the trunk of the great Artery lyeth vpon them) and before it depart altogether from the Liuer, it diſperſeth certaine ſmall branches into his ſubſtance which are not in all men of the ſame number. After it leaueth the Liuer, it diſcendeth inclining ſomething obliquely inward and diſpoſeth from it ſelfe many branches of which we will now intreat.

The deſcending trunke of the hollow veine.

The lower trunke of the hollow veyne [tab. 5, [x]] is diuided into a trunke and branches. From the trunke which runneth vnto the great rack bone as *Hippocrates* cals it, or to the holy-bone, [tab. 5, [n]] commonly there iſſue foure veynes on each ſide.

The firſt is called *Adipoſa ſiniſtra* the left fatty veine. [Tab. 5. [s].] It iſſueth out of the left ſide of the trunke (although *Euſtachius* be of the contrary minde) and preſently being diuided ſendeth one part to the fat, and to the vpper part of the vtter membrane of the kidneyes for their nouriſhmenr as farre as to the middle of the kidneys. It ſendeth alſo to the glandule which groweth aboue the kidney and to the midriffe it ſelfe [Tab. 5. [A·]] which veines on the inſide are very conſpicuous and vnited with the veines of the midriffe.

Adipoſa ſiniſtra

The other part it diſtributeth into the lower part of the foreſayde membrane.

The right branch ariſeth rarely from the trunke, moſt what from the vpper part of the middle paſſage of the emulgent [ta. 5. [f·]] becauſe the liuer which in this place is ſomwhat thicke [tab. 5. [B c·]] & ſtoppeth vp or intercepteth the way vnto the hollow vein, and therefore the left is for the moſt part aboue the right, yet it is diſtributed after the ſame manner that the left was. And ſometimes perforateth the glandule which groweth vpon the kidney with a ſurcle, which afterward is conſumed into the vtter membrane of the kidney. It is very rare if both of them be produced from the Emulgent; more rarely do the two veins iſſue from the hollow vein aboue and neere the original of the Emulgent. The vpper of them reacheth a ſmall branch vnto the glandule, the lower is by another ſurcle ioyned to the branch which runneth from the ſeede veine of the ſame ſide.

Dextra.

Their originall diuers.

But if the left Emulgent be the higher, then ſometime out of it the left *fatty veine* taketh his originall and the right from the trunke. So ſometimes on the right hand betwixt the fatty veine and the Emulgent there iſſueth another veine which ſprinkleth his branches vp into the midriffe, into the vpper part of the ſubſtance of the kidny and into the glandule of the ſame ſide.

After-

Afterward when the trunke of the hollow veine hath attayned vnto the twelfth Rackbone of the Cheſt, and the firſt of the Loynes, then yſſueth out of it the Emulgent.

The Emulgent which is the ſecond of the foure we before made mention of, is ſo called from his office or function. In like manner becauſe it is inſerted into the Kidney, it is called *Renalis* the *Kidney-veine*. The Emulgents.

[*Table 5 is the ſame with Table 8. Lib. 3. Folio 115.*]

It is the largeſt of all the veines that yſſue out of the Trunke [Ta. 9.d] for it is very thick yet ſhort becauſe they are as it were drawing ſtomackes and ſeruiceable to the Kidneyes. In Men and Apes they are on either ſide commonly but one, [Tabl. 5. vnder d e] notwithſtanding ſometimes the right Emulgent is double, euen from his originall as appeareth in the third Table of the fourth Booke the firſt Figure Char. 1. and 2. Sometimes it is treble, rarely double on either ſide, and this variety is not onely found in diuers bodies, but alſo in one and the ſame, ſo as the veſſelles of the right ſide differ much from thoſe on the left.

Their originall is ſeldome directly oppoſite one vnto the other, leaſt the function or office of one ſhould be interrupted. But the left is higher then the right in men but not in Dogges, becauſe the left Kidney by reaſon of the ſmalnes of the Spleen, ſtandeth higher, whereas the right is borne downe into a lower place by the magnitude of the Liuer. [Tab. 5.] The left Emulgent alſo is larger then the right, becauſe of the Spermatical veine which was to ariſe therefrom. Sometimes alſo from the lower part of the left Emulgent where it is implanted into the Kidney, there yſſueth a ſmall braunch which is tranſmitted vnto the lower part of the fat membrane, and is oftentimes ioyned with the Spermaticall. The iourneyes of both the Emulgents is ſhort and oblique, as appeareth in the third Tab. of the fourth booke; and about the middle and concauous Region of the Kidney before they get into their cauity, oftentimes in the very middle of their paſſage they are deuided into two or three, more ſeldome into foure or fiue equall braunches, which *Hippocrates* in his booke *de oſſium Natura*, compareth to Anchors faſtned in the cauity of the Kidney. Theſe braunches of the Veine and the like of the Artery are implanted into deuided parts of the Kidneyes not aſcending, which is rare and then only when it yſſueth out of a lower place, but deſcending, and thoſe braunches are in great numbers ſubdiuided into the ſubſtance of the Kidneyes till they become as ſmall as hayres. their original. Their progreſſe & diuiſion.

The vſe of theſe Emulgents is to ſuck and draw the whaey or ſerous moyſture from the blood and to drayne it, they conuay alſo therewith a part of the bloud it ſelfe for the nouriſhment of the Kidneyes, but leaſt this bloud and whay ſhould returne backe into the hollow veine, Nature hath placed values or flood-gates, as it is alſo in the Veines of the Spleene. Their vſe.

The third veine that yſſueth from the deſcending trunke, is called *Spermatica*, or *Seminalis* the Seed-veyne.

The right of theſe [tab. 5 h] which is ſometimes double, ariſeth with a ſwelling originall from the vpper ſide of the Trunke below the Emulgent rarely cloſe to it, from which notwithſtanding ſomtime it receiueth a ſmall branch. The left ariſeth [tab. 5, i] almoſt alwayes from the middeſt on the lower ſide. The reaſon whereof is becauſe if it ſhould haue ſtradled ouer the great Artery, [tab. 5, L] ſo ſmall a veyne would haue beene indangered by his pulſation: for eyther the continuall motion muſt haue broken it, or at leaſt haue interrupted his office.

There is alſo ſomtime ioyned to this left Seed-veyne, a branch iſſuing from the trunk it ſelfe. The reaſon was, becauſe the blood of the Emulgent being wateriſh, might bee aſsiſted by the purity of the blood of the hollow veyne.

Theſe Seed-veynes deſcending obliquely, and paſsing through the productions of the *Peritonæum* or rimme of the belly aboue the ſhare-bone, at the head of the Teſticles are diuerſly contorted and ſo attaine vnto that which they call *Varicoſum corpus* or the *Bodden body* leading thether from the whole body the matter of the ſeede, as we haue ſhewed before in the fourth booke,

But in women although their originall be the ſame, yet they fall not out of the *Peritonæum*, neyther do they reach ſo farre as to the ſhare-bones, but beeing ſupported with fat membranes are diſſeminated part of them vnto the Teſticles, part vnto the bottome or ſoale of the wombe.

More-

Moreouer they affoord ſlender ſurcles to the Rimme of the belly and to the coats which inueſt the Teſticles.

Lumbares. The fourth veſſell that departeth from the lower trunke, is called *Lumbaris* or the *Loyne-veyne*. They are two [tab.5, mmm] or three ariſing from the lower part of the trunk, which is next vnto the ſpondels betweene foure rack-bones of the Loynes, & they paſſe through the holes made for the out-gate of the nerues in the ſides of the racke-bones. Their vſe is to water and nouriſh the ſpinall marrow.

Their vſe.

Hippocrates. From theſe two veynes on each ſide one aſcends into the braine at the ſide of the ſpinall marrow which haply are thoſe whereof *Hippocrates* maketh mention in his booke *de Genitura*, and it may be they bring a portion of the matter of the ſeed down frō the brain, whereof *Ariſtotle* in his Problemes was ſo confident that he ſayth it hath beene ſeene.

After the departure of theſe foure veynes the Trunke deſcending vnto the *holy-bone* [Tab.5, n] at the fourth rackebone of the loynes inclineth vnder the great artery, [Tab.5, charact.14,] that it might neyther be hurt by the hardnes of the bone, nor offended by the continuall motion of the Arterie, and is diuided into two equall branches called *Rami Iliaci* or the *Illiack* branches which reſemble the letter ʌ or ɣ inuerted, which run obliquely aboue the haunch and the ſhare-bones vnto the legge. Out of theſe on eyther ſide before the diuiſion do iſſue two veynes. The firſt is called *Muſcula ſuperior* [Tab.5 npnp] the *vpper muſcle veyne*, which ariſeth euen in the very diuiſion frō the vtter ſide of the branch, ſometime it iſſueth out of the trunke of the hollow veyne before the partition, and is tranſuerſly or ouerthwart diſſeminated through the muſcles of the Loynes of the *Abdomen* and through the rim of the belly; but their originall is not the ſame on both ſides; & in dogs it is more manifeſt then in men. The ſecond is called *Sacra*: [tab.5, oo] or the holy veyne. It is but ſmall, ſomtimes ſingle, ſomtimes double, and it is conuayed through the vpper and forward holes of the hollye bone to nouriſh his marrow.

The Iliacke branch.

Muſcula ſuperior.

Sacra.

Afterward the Illiacke trunke on eyther ſide in his progreſſe [Tab.5, r] is bifurcated into a vtter branch, [Tab.5, s] and an inner, [Tab.5, t] and the latter is ſmaller then the former: from the inner branch proceed two veynes.

Muſcula media The firſt is called *Muſcula media* [Tab.5, fff] the *middle muſcle* veyne. It is the outward propagation of the inner branch, and is deriued tranſuerſly [Tab.5, x] with many ſurcles into the muſcles of the thigh which occupy the vtter part of the hips, into the skin of the buttocks, and into the neighbour parts.

Hypogaſtrica. The ſecond is called *Hypogaſtrica*, [tab.5, uu] the veyne of the water-courſe. It is the inner propagation of the interior branch. A notable veyne it is and ſometimes double, & is diuided manifold, becauſe it was to be diſtributed for the nouriſhment of al the parts almoſt in the *Hypogaſtrium* or Water-houſe. One part of it runneth vnto the muſcles of the right gut, and maketh the outward Hemrod veynes by which ſomtimes an abundance of thinne blood, falling hether out of the hollow veyne, is auoyded without payne or torments of the belly; ſometime alſo without paine in the Fundament, wheras the blood that iſſueth from the internall Hemrods made by the branch of the Gate-veyne is alwaies paineful in the auoyding. Another part runneth out in men vnto the bladder with great & large ſurcles, into the neck, I ſay, of the bladder and into the yard. But in women it is but a little lengthened, & beeing ſuſtained with a fat membrane it diſperſeth ſome ſurcles into the bladder but many more into the lower part of the wombe and the necke thereof, by which oftentimes in womē with child, & as ſome ſay in Virgins the courſes are auoided.

The outward Hemrod.

That which remaineth of his interior branch paſſeth on vnto the ſhare-bone and aſſumeth vnto it ſelfe a little rillet from the external branch, which together make a veine [Tab.5, y] which perforateth the Rim of the belly, and after alſo the tenth muſcle of the thigh, and goeth through the hole of the ſhare-bone.

From the outward. From the vtter branch of the byfurcation of the Illiack trunke. [ta.5, r] which attaineth obliquely vnto the thigh do iſſue three veynes: two before it fall through the *Peritonæum*, and one after.

Epigaſtrica. The firſt is called *Epigaſtrica*. [ta.5, char.1 & 2] It iſſueth from the vpper part of the vtter branch: ſomtimes alſo but more rarely from the Crurall, and offereth branches to the rim of the belly and to the muſcles and skin of the *Abdomen*. The chiefe branch of this veyne piercing through the *Peritonæum* runneth vpward on both ſides vnder the right Muſcle diſtributing diuers ſmall branches into the tranſuerſe and oblique muſcles and about the Nauill is ioyned by ſome ſurcles to the Mammary veyne that deſcendeth thether, by which *Bauhine* thinketh that notable conſent is made betwixt the breaſts

breast and the wombe, for those Veines haue their originall from the same deuision, from whence those other haue it which attaine vnto the wombe and the bosome thereof. For their endes or extremities ioyne with the extremities of the *Mammary* veines which descend through the capacity of the chest, and runne as farre as to the middle of the right Muscles, and in their descent doe send branches through the distances of the gristles vnto the roots of the Pappes.

The second is called *Pudenda*. [Tab.5.char.15.] It ariseth from the inside of the outward bow after it hath gotten ouer the *Coxa*, and fallen into the thigh, and perforated the *Peritoneum* or Rim of the belly. It reacheth ouerthwart to the middle of the share bones, and is distributed with a wonderfull increase, in men into the *Scrotum* or Cod, and into the skinne of the yard, in women into the place of modestie, and the neighbour parts. *Pudenda.*

The third and last is called *musculà inferior* [Tab.5 char.17.] *the lower muscle veine*. It issueth from the outside of the vtter branch Tab.5.c.] and running through the ioynt of the hip, is disseminated into the muscles and skin of that place. Musculà inferior.

The rest of the propagations which issue from both the trunkes [Taq.5.p.] because they bee no longer called Iliacke but Crurall veines, wee will intermit till the tenth Chapter.

CHAP. VI. *Of the ascending Trunke of the hollow veine.*

WE diuided the hollow veine into a Descending and an Ascending trunke; the Descending we haue prosecuted in the former chapter, the Ascending we take now for our taske.

The hollow veine therfore after it hath passed through the nervous part of the midriffe, on his right side by a hole of purpose for it paceth on through the Chest with his trunk vndiuided [Ta.6.fig.1.from ^ to ^p. Ta.7.from ^s to ^n.] euen to the *Iugulum*, that is, the hollownesse aboue the coller bone. It is a larger trunke then the Descending, for it was to leade blood vnto more parts, and for more security is ioyned to the midriffe, and to the right *deafe eare* of the heart. *Laurentius* saith it toucheth the *Mediastinum* likewise. In men there is question whether it do or no; *Vesalius* is against it, but in Dogges and Apes, sayth *Bauhine*, it doth without doubt. And least in the *Iugulum* it should be hurt by the hardnesse of the bone, and also that it might more safely be diuided into notable branches; there is a glandulous body couched vnder it called *Thymus*, in calues it is called the *Sweete-bread*. In Dogges and Apes (*Galen* saith also in men) a lobe of the Lungs is layde vnder it betweene the Purse of the heart and the midriffe, for their chests are longer then is a mans. The Ascending trunke.

Before the diuision there issue out of the trunke foure branches.

The first is called *Phrenica* [Tab.7.c.] or the veine of the midriffe, one either side one, which is disseminated through the midriffe in many surcles, and sendeth small branches to the *Pericardium* or purse of the heart, and to the *Mediastinum* or partition of the chest. The right of these issueth sometimes within the cauity of the chest; the left ariseth out of the trunke vnder the midriffe, wherewith also sometimes the Fatty veine called *Adiposa* is ioyned. Presently the trunke of the hollow veine pacing one and perforating the *pericardium*, and inclining a little to the left hand [Tab.7. aboue ^n.] maketh a brode *sinus* or bosome before the hart ouer against the 8 rackbone of the chest or the top of the ninth; somtimes in the middle space which is between the seuenth and the eight racks. Where changing almost his substance and his roundnesse it degenerateth in the right deafe eare, [Tab.7.^p.] of the heart; or if you will it is on euery side fastened to the right eare which it superficially embraceth. There it is infixed into the right ventricle of the heart, not penetrating very deepe, to the end it might poure blood into it as into a Cysterne. *Phrenica.* His fastning to the heart.

Eustachius saith that there is a certaine membrane set to the fore and inner side of the hollow veine, which at the middle of the perforation determineth into many fibres, which being diuersly complicated doe make vp or fulfill the rest of the semi-circle, and without coniunction are spread ouer the whole perforation, that so the same membrane might be put forward and repelled backeward by the matter that rusheth in or out. But this membrane sometime wanteth that texture or fibres, and resembleth the forme of the Mitred or horned Moone, as it is in the crowne veine. It is also sometime so small and narrow that, as if it were not all, it is vndescryed; which haply, saith *Bauhine*, is the reason that I haue not yet obserued it. Eustachius his value.

The

Coronaria cordis.

The ſecond branch which iſſueth from the thumbe before the diuiſion is called *Coronaria Cordis* [Tab.6.fig.2.[a]. tab.7.[a].]the crowne veine of the heart, for, becauſe it compaſſeth the baſis of the heart,like a crowne or garland, the Grecians call it στεφανιαῖα. It ſendeth many brãches through the vtter ſurface of the heart all ouer the bowell from the baſis downeward vnto the *Mucro* or poynt, eſpecially through his left ſide, for, becauſe the ſubſtance of the heart is there the thickeſt it ſtood in need of more plentiful Aliment, and becauſe it required a thicke nouriſhment conuenable or agreable to his ſubſtance, therefore it receiueth bloud by this veine before it get into the ventricle,where the bloud becomming thinner is deſtined for the nouriſhment of the Lungs.

His value.

At the originall of this Crowne-veine there is placed a value or flood-gate like a halfe Moone, reſembling that which in the heart of the Infant is ſet before the firſt *Anaſtomoſis* or inoculation. This Value keepeth the bloud that is once allowed to the Surface of the heart that it flow not back into the hollow veine,being ſhaken by the continuall motion of the heart. This *Crowne-veine* (ſayth *Galen*)is ſometimes double; one on the backſide,another ariſing from the foreſide.

When the hollow veine hath allowed this garland to the heart it perforateth the purſe thereof againe,and againe reſumeth his round figure and becomming much leſſer forſaketh the Rack-bones,becauſe vpon them the Gullet and the rough artery doe leane,and runneth through the middeſt of the lungs where the right part is ſeparated from the left, vpward vnto the *Iugulum* aboue the *Thymus*.

But that the Racke-bones and the ſpaces betwixt the ribs might not be deſtituted of Veines; it yeildeth forth a trunke or notable veine aboue the heart as it were in the verie middeſt of the body.

The veine Azygos.

This veine which is the third before the diuiſion of the Trunk is called *vena ἄζυγος*,or *ſine pari*,the Veine without a companion,which we haue before called the *non-parill*.[Ta.6. fig.1.C fig.2.B fig.4.B] The reaſon is becauſe commonly in a man it is but one as alſo in a Dogge hauing no mate on the other ſide. It ariſeth aboue the heart betwixt the fourth and fift Racke-bones of the Cheſt, out of the hinder [Tab. 6.fig.4. A] and lower part of the hollow veine as it regardeth the Rackes, but rather to the right hand then to the left.

Veſalius taxeth *Galen* very deeply for inconſtancy and irreſolution concerning the originall of this veine,to all whoſe obiections *Bauhine* maketh anſwere,wherwith we could willingly make you acquainted,if we did not thinke that ſuch altercations are fitter for other palats then we deſire to be Cook vnto.

In Dogges after the originall it ſinketh directly downward to the ſides of the Rackes, but in men it goeth not directly, but is reflected a little to the right hand and backeward toward the ſpine aboue the right trunke of the rough Artery. When it hath touched the rootes of the Rack-bones it is lifted vp, and paſſing on to the midſt of them it deſcendeth downward,ſo that aboue the eight or ninth Rack-bone of the Cheſt it is in the very middeſt,and runneth downeward vnder the Artery,which beareth vppon it as farre as to the end of the Cheſt (but deuided before) and with the great Artery peirceth thorough the Midriffe. In moſt creatures,in which I woulde haue young men exerciſe themſelues, it taketh his originall from the left ſide of the hollow veine,and deſcendeth (ſayeth hee) through the cauity of the Cheſt on the left ſide; which indeede in Sheep is alwayes true, but in thoſe creatures which chew the Cud in whome it is double, (which in men is very rare, vnleſſe you will ſay it may bee ſo in thoſe that bee Ambidexters,that is,can vſe both hands alike,) the right occupyeth the rootes of the ribbes on the right ſide, and the left the rootes of the ribbes on the left ſide.

The veine deſcribed by Falopius.

In like manner ſometimes as we are taught by *Falopius* [ta.8.i] there is found in men on the left ſide another veine [Ta.8.i] which performeth the office of the *Azygos*,& then the other on the right ſide paceth neare the roots of the ribbes, but ariſeth not aboue the middle of the racke-bones.

[*Table 7.is the ſame with Table 6.lib.7.Folio* 445.]

This laſt Veine taketh his originall from the *ſubclauian* branch, and affoordeth ſmall ſurcles to ſome of the ſpaces betwixt the ribs,& ſometimes at the fift rib is vnited with the branch which from the Trunke of the *non parill* is ſent ouerthwart[Ta.8.[ee]]to the left ſide ouer againſt the ſixt Racke of the Cheſt, from which alſo a ſmall braunch ariſeth vpward. Sometimes it ariſeth not from the *ſubclauian* branch,but out of the Trunke of the hollow veine

veine before his deuiſion againſt the third Racke-bone of the Cheſt, and ſendeth ſmall branches vpward to the two firſt ſpaces betwixt the ribs. His other ſurcles it affordeth to the lower ſpaces of his owne ſide, as farre as to the fixt Rackbone, whether when it hath attayned, it is joyned with the foreſaide tranſuerſe branch, from which ſurcles are ſprinkled into the reſt of the diſtances betwixt the ribs.

The *Intercoſtall* veines.

Commonly from the trunke of the veine *Azygos* ([Ta.6.fig.4.[b] tab.7.[m] ta.8.[d]] which is ſeated as it were in the middle of the body, out of the backward Region, I ſay thereof, as well on the right hand as on the left but from the right eſpecially, branches are diſtributed to the diſtances of the ten lower ribs, [Ta.6.fig.4.] ſometimes but rarely to all the diſtances of the ribs, and thoſe branches are called *Intercoſtales* [tab.7.[oo]] paſsing along in the diſtances of the true ribs as farre as to their griſtles: but in the diſtances of the baſtard ribs they run out to the muſcles of the *Abdomen*.

It diſtributeth alſo an aboundance of ſmall branches to the Gullet, ſometimes and that not ſeldome, when it ariſeth from againſt the fourth racke-bone of the Cheſt, it ſendeth a branch vpward, [tab.8. at the vpper [d]] from which ſurcles are deriued with a wandring paſſage to the foure vpper ribs.

The propagations of the *Intercoſtall* veines doe fall alſo out of the Cheſt, [Ta.8.xxx] and on both ſides in ſome places are vnited by inocculation [Tab.8.[yyy]] with the ſurcles of the lower *Cheſt-veine*. Whence it is that in the *Pleureſie* we doe not alwayes vſe, as *Veſalius*, to open the veine on the right ſide, but finde it profitable to Phlebotomize the inner veine of the cubite on the ſame ſide the paine is. But becauſe of this vnion, revulſion is made more commodiouſly and more eaſily.

2. boughes of the *Azygos*.

When the Trunke of the Veine *Azygos* hath attayned to the eight and ninth ribbe, ſometimes to the tenth ſayth *Hippocrates* in his book *de natura oſsium*, it is deuided aboue the Spine into two boughes: a right and left, which *Falopius* and *Euſtachius* did firſt obſerue, [Ta.6.[c°]] both which doe creepe downeward and paſſe through vnder the diuiſion of the Midriffe.

The left.

The one of theſe, and for the moſt part the greater, on the right hand determineth moſt what with one branch into the backeſide of the hollow veine, neare the beginning of the Emulgent. Sometimes into the middle of the Emulgent, [Ta.8.[ee]] where it bringeth forth the Seede-veine. Sometimes againe it is reflected in the cauity of the backe, and vnited againe with a ſmall branch yſſuing from the Emulgent. Sometimes alſo this left branch is deuided into 2. branches, one of which runneth vpward [ta.6. fi.4.[c°]] the other downward by the roots of the ribs, & affordeth branches to the diſtances betwixt the.

The right.

The right bough approaching to the hollow veine, is ſometime ioyned thereto aboue the Emulgent, ſometimes it is ioyned to the Emulgent it ſelfe, but that rarely: Sometime to the firſt veine of the Loynes, but moſt commonly it is implanted into the laſt [Ta.8.[ee]] of the Loynes. VVe alſo finde in ſome bodies a ſmall branch running obliquely by the Racke-bones, and penetrating or making way into their cauity. VVhereupon wee conclude, that in the beginning of a *Pleureſie* the Veine of the Hamme or that of the Foote called *Saphena* may be opened.

How the cheſt is purged by vrine.

Hence alſo it is that many *Pleuriticke* Patients are critically purged, Nature auoyding an aboundant quantity of *Pus* and *Matter* by the vrine. Moreouer it hath beene obſerued that in thoſe which we call *Empyici*, the *Matter* hath beene conuayed through the venall Artery of the Lungs into the left ventricle of the Heart, thence into the great Artery, and ſo into the Kidneyes, and continually auoyded by the vrine. VVherefore this diſtribution of the Veine *Azygos* and his vnion ſheweth howe the Cheſt may commodiouſly be purged by the vrine. The Rackbones alſo along which it runneth and the *Mediaſtinum* receiues ſurcles herefrom.

No values in the *Azygos*.

Nowe whereas *Amatus Luſitanus* in his Centuries, and with him *Hollerius* affirme that the beginning of this veine hath Membranes or Flood-gates, ſuch as are found in the orifices of the veſſelles of the heart which admitte the ingreſſe of the bloud out of the hollow veine into this *Azygos* but hinder the egreſſe; they are much deceiued ſayeth *Bauhine*: for I could neuer obſerue any ſuch eyther in men or in bruite beaſtes. Adde hereto that if you open this *non-parill* below, preſſe it out and put a bugle thereinto, when you blow the bugle, not onely this veine but the hollow veine alſo will ſwell. Their opinion therfore falleth to the ground, who think that when a veine is opened in the arme, though the hollow veine be emptyed, yet there is no depletion made out of the *Azygos*, becauſe

though thoſe values do hinder the egreſſe of the blood into the hollow veyne.

Intercoſtalis ſuperior. The fourth veine that ariſeth out of the trunke before the diuiſion is called *Intercoſtalis ſuperior*, the vpper Intercoſtall veine. [Tab.6.fig.1,* Tab.7,*] There is one of them on each ſide ariſing from the ſubclauian branch neare the beginning of the Iugular veyne. [Tab. 7,ss.]

Sometime the right veyne ariſeth from the trunke, and the left from the branch. It is reflected vnder the Artery of the arme, and for the moſt part eſpecially on the right ſide is diuided into two branches which are diſtributed ſometimes into two, ſometimes into three diſtances of the vpper ribs which are ioyned with the mammary branches [Tab. 7,ll] which creepe through the griſtles. This veyne is then wanting when the *Azygos* affoordeth branches vnto all the diſtances of the ribs.

In like manner from all the Intercoſtall veynes there iſſue certaine ſmall ſurcles which inſinuate themſelues into thoſe holes of the rack-bones, out of which the nerues do iſſue for the nouriſhment of the bones and the ſpinall marrow.

The diuiſion of the trunke. The trunke of the hollow veyne beeing deliuered of theſe veſſels [table.7,*] aſcendeth directly vnder the breſt-bone aboue the great artery at the Iugulum, where it is ſupported by the *Mediaſtinum* and the *Thymus*, and is diuided into two notable bowes, [Tab.7,ll tab.8,cc] one of which runneth to the right ſide, the other to the left, and as long as it remaineth in the Cheſt it is called Subclauius. *Columbus* and *Fa'opius* call it *Axillaris*.

Table 8 is the ſame with Table 7, Lib.6, folio 363.

The ſubclauian branches. From each ſubclauian branch ſome veynes iſſue from the lower part, ſome from the vpper. From below before the ſubclauian is diuided do ariſe foure veynes or branches. *Mammaria deſcendens.* The firſt is called *Mammaria deſcendens* [tab.6,fig.1,ll tab.7,ll tab.8,l] *The deſcending mamary veine* whoſe originall is diuers, for ſometime it ariſeth frow the fore and middle part of the byforcation, ſometime from the roote of the ſubclauian, ſometime the left ariſeth from the ſubclauian and the right from the byfurcation. Sometime there is but one which ariſeth out of the middle of the trunke of the hollow veyne before the diuiſion, which when it hath attained vnto the breſt-bone is diuided into a right and a left.

This mammary veine inclining forward and running vnder the breſt-bone, getteth out againe at the ſides of the griſtle, which we called the breaſt-blade, and creepeth along the vpper part of the *Abdomen*, allowing ſurcles thereto, and in his deſcent affoordeth ſmall branches to all the griſtly diſtances of the ribs (for the bony diſtances are ſupplied by the *Azygos*), which are ioyned with the extremities or end of all the intercoſtall veynes. A part of this mammary veine getteth out of the Cheſt and to the muſcles that lye therupon and when it hath diſtributed his ſurcles part vnto the paps, part vnto the reſt of the breſt, it is led downeward vnder the right muſcles of the *Abdomen*, to which his branches are tyed and the extremities of his diuiſions do vnite [Tab.7,*] with a ſmall Epigaſtrick veine [ta.7,f], which aſcends vpward. Other ſmall veſſels alſo run vnder the skin to the *Hypocondria*, which veſſels are made partly of the commixtion of the Intercoſtall veynes with the mammary, partly of thoſe which nouriſh the Intercoſtall muſcles, with which alſo others are vnited which aſcend from the groyne vpward.

The ſecond veyne iſſuing from the ſubclauian before his diuiſion is called *Mediaſtina* [Tab.2,lib.6,*] which ariſeth from the trunke, ſometimes from the left ſubclauian againſt the interuall Iugular. Sometime it is but one veyne and that large deriued downeward aboue the hollow part of the Lungs and aboue the purſſe of the hart, and is diſſeminated thorow the *Thymus* and the *Mediaſtinum*. Sometime they are two ſurcles which runne through the *Mediaſtinum*, one of which is ioyned with the aſcending veynes of the Midriffe, the other paſsing downeward with the left nerue of the midriffe, is inſerted into his fleſhy ſubſtance, and this inſertion is better perceiued in young bodyes then in Auncient.

Cervicalis. The third veyne is called *Cervicalis*, [Tab.6,* Tab.7,**] or the necke-veine. It is not very large, and runneth obliquely vpward and backeward by the laterall proceſſes of the racke bones of the necke, and paſſeth the holes made in them, affoording ſurcles to the muſcles that lye next vpon the bones. It ſendeth alſo others through the holes made for the nerues to nouriſh the marrow of the necke, and ther is conſumed. *Laurentius* thinketh it aſcendeth vnto the braine.

Muſcula inferior. The fourth is called *Muſcula inferior*, [Tab.7,*] the lower *Muſcle*-veyne which ſome-

ſometime yſſueth out of the externall Iugular, and is diſtributed through the vpper muſcles of the breaſt and the lower of the necke. And theſe foure iſſue from the *ſubclauian* branch before it get out of the cauity of the Cheſt. Afterwards when it is gotten out of the Cheſt [tab.8 r] it changeth his name and is called *Axillaris*. From the axillary veyne before it be diuided, two veines are propagated.

The firſt is called *Scapularis interna* [Tab.7.q] the inner blade veine and is diſtributed through the muſcles on the inſide of the blade, and thoſe that are neare them, where alſo thoſe ſmall branches doe appeare which paſſe through the glandules that are vnder the arme pits. *Scapularis interna.*

The ſecond is called *Scapularis externa* [tab.7.d] the vtter blade veine, becauſe it paſſeth into his gibbous and vtter part: the other part of it runneth betweene the fleſh and the skin. *Scapularis externa.*

Afterward the axillary branch is diuided into two veines, [tab.6.x tab.7.a m] one ſuperior which is called *Cephalica*, [Tab.7.a tab.8.a] or the head veine. The other inferior [tab.7.m Tab.8.l] called *Baſilica* of both which we ſhall ſpeake in the ninth chapter. In the meane time you ſhall know that from the trunke of the *Baſilica* two veines doe iſſue. *Cephalica. Baſilica.*

The firſt is called *Thoracica ſuperior* [Tab.7.pp Tab.8.f.] the vpper cheſt veine, which applyeth it ſelfe to the breſt, and is diſtributed into the skin and the muſcles which couer the breſt: in women it yeeldeth a great number of veines vnto the dugs. *Thoracica ſuperior.*

The ſecond is called *Thoracica inferior* [Tab.7.xx. tab.8.t t.] the lower cheſt veine. It runneth all along the ſide of the cheſt and his branches are inoculated [Tab. 8.yy] with the branches of the veine *Azygos* [tab. 8.xx] which iſſue out of the cheſt (wherefore we may draw blood in a pleuriſie out of the axillary veine of the payned ſide) and are diſtributed through the broade muſcle of the arme. This lower cheſt veine ariſeth ſometimes out of the vpper, ſometime out of the *Baſilica*. And thus much for the veines ariſing from the lower part of the *ſubclauian* branch. *Thoracica inferior.*

From the vpper part of the *ſubclauian* branch ariſe three veines on each ſide. The vpper muſcle veine and the two Iugulars, one externall another internall, which aſcend vnto the ſides of the necke, and at whoſe orifices there are two values which hinder the relapſe of the blood, for otherwiſe the vpper parts ſhould haue beene defrauded of Aliment.

The firſt I ſayde was called *Muſcula ſuperior*, [tab. 7.bb, tab, 8.o] the vpper muſcle veine. It ariſeth neare the externall Iugular [Tab.8.n] and is diuerſly diſperſed into the skin and muſcles that are on the backe ſide of the necke. *Muſcula ſuperior.*

The ſecond is called *Iugularis externa* [tab.6.fig.1, ll tab.7.rr. tab.8.n] the externall Iugular veine. It is one commonly on each ſide, yet ſometimes double from the originall ſometime it groweth double in the middeſt of his paſſage. It runneth vpward vnder the skin affoording ſurcles to all the outward parts of the necke, of the head and of the face on his owne ſide, and for the moſt part vnder the roote of the eare it is diuided into an vtter and inner branch, as we ſhall ſay in the next chapter when wee ſpeake of the veines of the face. *Iugularis externa.*

The third and laſt is called *Iugularis interna* [tab.6, fig.1, xx tab.7.rr tab.8.m] the internall Iugular veine. In man becauſe of the aboundance of his braine it is greater then the externall, but in Dogs leſſe. At the ſide of the rough artery it ſendeth ſmall ſurcles therto and to the neighbour membranes, thence it climeth vnto the chops, and hard at the head is byfurcated or diuided, and there we leaue it. *Iugularis interna.*

CHAP. VII. *Of the veines of the Face, the Eyes, the Noſe, the Teeth and the Throttle*

WE ſayd euen now that the externall Iugular veyne was vnder the roote of the eare diuided into an vtter [tab.7.s] and an inner branch. [x] The inner runneth to the muſcles of the mouth, the chops, and the bone *Hyois*. In the mouth it maketh thoſe two notable veins vnder the tong [tab.7.t] which from their colour rather then from their figure are called *Ranina* the Frog-veines which veins in diſeaſes of the mouth, the heate of the throate and the ſquinſie are opened for deriuation after euacuation and reuulſion made by the vaine of the arme. From it alſo are many ſurcles deliuered ouer to the Larynx or throttle, to the glandules thereto growing and to all the parts of the chops for their nouriſhment. Afterward approa- *Ranina.*

ching to the skull it entreth thereinto through a hole of the temple bone neare the mammillary proceſſe and ſo goeth into the *ſinus* of the *dura mater*. There alſo paſſeth a vein on the outſide of the orbe of the eye, by the hole of the wedge bone which is likewiſe diſſeminated into the *dura mater*.

The vtter branch.

The vtter branch creeping vp the skin, and the muſcles of the head vnder the eare is ſupported with Glandules, and diuided with two propagations. One of which runneth to the foreſide of the face [tab.7 z] and is allowed to the noſe and the puffe of the cheeke and in the middle of the forehead it is ioyned with the branch of the other ſide, and maketh the veine of the forehead [tab.7 a] which in ſome caſes is wont to be opened. Another propagation thereof runneth by the ſide of the head, and ſprinkleth veines partly to the temples [tab.7, a] partly to the Nowle of the head. [tab.7 *] The branches of this exterior veine are diuerſly mixed in the face and the ſides of the heade: from which ſome ſmall ſurcles are diſtributed into the ſutures of the ſcull and the ſmall holes or perforations thereof. And ſo much of the externall Iugular, now we come vnto the internal, where we left it at his bifurcation hard at the Head, in the end of the chapter going before.

Vena Frontis.

CHAP. VIII. *Of the Veynes diſſeminated through the Braine.*

The inner Iugular.

THE inner Iugular veine when it attaineth on the backſide to the Baſis of the Scull, is diuided into two branches wherof the one which being the larger is carried backward, the other which is the ſmaller is carried forward,

The firſt of the Braine.

The firſt is led along the baſis of the Scull with the leſſer branch of the ſleepy artery, and when it hath affoorded ſurcles to the Muſcles which lie vnder the gullet, it getteth into the ſcull and ſo into the *ſinus* of the *Dura mater*, through the firſt hole of the Nowle-bone which was prepared for the ſixt paire of ſinewes.

The ſecond.

The ſecond which leaueth the ſleepy Artery, ruuneth forwarde after it hath ſent a ſurcle to the organ of Hearing through the fourth hole of the Temple bone, it entreth into the ſcull by the ſeuenth hole of the Wedge-bone and walketh through the baſis and the ſides of the *Dura mater* or thicke membrane leading them Aliment, becauſe they are far diſtant from the third *ſinus*: from theſe alſo do yſſue ſome ſurcles which creepe vppe the *Pia Mater*.

The third.

Bauhine accounteth the third veine of the braine to bee the inner branch of the externall Iugular which diuideth it ſelfe into three ſurcles, and entereth into the ſcul by the hole of the temple-bone which is neere the Mammillary proceſſe, of which wee ſpake in the former chapter.

The 4 and 5.

The fourth and the fift Veynes of the Braine he ſaith do proceede from the ſame interiour branch of the externall iugular, the fourth entreth into the ſcull out of the orb of the eye by the ſecond hole of the VVedge-bone, the fift out of the capacity of the Noſethrils by the hole of the *ſciue* or ſpongy bone. The vſe of theſe two latter Veins is to nouriſh the fore-part of the Braine, becauſe vnto it the third *ſinus* dooth not reach but determineth neere the diſtinction of the Mammillary proceſſes. Theſe Veynes alſo becauſe they are ſmall haue no Arteries ioyned with them, yet there is a ſurcle ſent thither from the firſt artery of the Braine.

Veſalius and *Platerus* add a fixt.

Beſide theſe fiue Veines *Veſalius* and *Platerus* affirme, that there is another which they call *The firſt Veine of the Braine*, which is the end of the *Neck-veine*. For when the Neck-veine commeth vnto the top of the necke that which remaineth of it, together with the Artery his companion, paſſeth through the third hole of the Nowle-bone, which poſtern was particularly made for this priuat vſe: or if that be wanting through the ſecond, which was made for the ſeuenth paire of ſinewes, and determineth on both ſides into the ſinus of the *Dura Mater*.

Falopius.

Bauhine ingenuouſly confeſſeth, that he could neuer finde this paſſage & yet makes mention of it, becauſe other men ſhould not want occaſion to enquire after it. For ſaith he, the Necke-veine is partly conſumed or taken vp in the perforations of the rackbones of the necke, yet ſo that it touch not the firſt racke: partly his braunches are diſſeminated into the backſide of the neck, hauing firſt tranſmitted ſomevnto the Muſcles in that place as we are taught by *Falopius*, which Veynes are vnited together among themſelues, and together alſo with others which are ſent out of the *ſinus* of the *Dura mater*, through the large hole of the ſcull, for there are many veines which from the *Dura Meninx* are propagated to the outſide of the head through the Sutures comming from without: which ſaith

Falopius

Falopius gaue occaſion to ſome to thinke that they were outwarde veines which went in through the holes of the Scull into the *ſinus* of the *Dura Mater*, whereas they are rather internall Veines which get out at thoſe holes and are ioyned with the externall.

The vſe of the veines of the Braine which are in innumerable multitudes diſſeminated into both parts thereof and into his marrow (and although ſome of them be ſo ſmal, that he which is not quick-ſighted cannot perceiue them, ſom of them conſpicuous enough) the vſe I ſay of them all is three-fold. The firſt to miniſter vnto the Braine his Aliment, that is Blood, and that in great aboundance, becauſe the quantity of the Braine is great. And truly that there is abundance of Blood in the head dooth eaſily appeare in diſſections after inflammations of the Braine. The vſe of the Veynes of the Braine.

Their ſecond vſe is to tranſmit vnto the braine naturall ſpirite from the Liuer for the nouriſhment of the Naturall ſpirit which is in the Braine.

The third, that together with the naturall ſpirit the naturall ſoule, which is called alſo *Vegitatiua* or the growing faculty, might be conducted into the braine, for becauſe in the braine there is a faculty to draw, retaine, concoct and expell the Aliment or ſuperfluities thereof, it is very neceſſary that it alſo ſhould haue in it the Naturall Soule either of it ſelfe or deriued from other where. But becauſe the ſeate of the naturall ſoule is concluded to be in the Liuer, it muſt needs follow, that it can no otherwiſe be conueyed to the braine but through the veines. *Archangelus.*

Archangelus addeth a fourth vſe of theſe veines of the Braine, and that is, that by the veines as alſo by the Arteries, the ſeede might be made fruitfull. For *Hippocrates* ſayth in his booke *de Genitura*, that thoſe are barren and vnfruitfull whoſe Veines behinde their eares are cut or diuided, and his reaſon was becauſe he thought that a great parte of the ſeede fell neere the eares from the head into the ſpinall marrow. But if the paſſage bee ſtopped vp by a Cicatrice growing vpon the wound of the veſſell, then ſhall the current of the ſeede be interrupted.

Concerning which difficulty and the interpretation of *Hippocrates* meaning, wee haue diſputed at large in the fourth queſtion of the fift booke, and therefore we will not trouble the reader heere with fruiteleſſe repition, but ſend him thither if he deſire to bee further ſatisfied concerning that matter.

Beſide the veines and other veſſels of the braine. It hath a priuate veſſell which is called the *ſinus* of the hard membrane; full of blood, but beating like an Artery, into which three Veynes and two Arteries do powre their matter, which ſinus according to the diuers courſe and inclination thereof is diuided into foure ſinus: greater indeede then the veines that attaine vnto the ſcull and more capacious, not round but triangular. The whole ſinus conſiſteth of three ribbes all of equall longitude, and of the fourth part of a circle incurued. From theſe do ariſe branches or paſſages like vnto veines, and doe diſtribute blood as well Vitall as naturall into the ſubſtance of the braine. But becauſe wee haue entreated ſufficiently hereof in our chapter of the membranes of the braine which is the ſeauenth of the ſeuenth Booke, where alſo we haue exhibited the figure therof vnto you, wee will heere put an end to the veines of the Brain, and paſſe on vnto the veines of the Arme. The *ſinus* of the Braine.

CHAP. IX. *Of the Veynes o the whole Hand in the large Acceptation.*

WE ſayde before that the Trunke of the Hollow-veine vnder the breaſt-bone at the very *Iugulum* or ſticking-place [Ta.9.fig.1 [n]] is diuided into two notable branches, [[r]] one of which runneth to the right hand, the other vnto the left, and as long as it is within the Cheſt it is called *Subclauius*, but after it is gotten out becauſe it runneth to the arme-holes it changeth his name and is called *Axillaris*, from which diuers Veynes do yſſue, of which we haue ſpoken before: but the Axillary veine departeth into two branches, one vpper which is called *Cephalica* [a] or the Head-veine, the other lower which is called *Baſilica*, [m] ſo that both of them haue the ſame Original, and of both of them will we intreat in this chapter. The trunk of the Hollowe-veine.

The *Cephalica* or head-veyne [a] is the vpper branch of the *Axillary*, but it iſſueth from the externall Iugular veyne. It is called *Cephalica* becauſe it is wont to be diuided or opened in diſeaſes of the head. It is alſo called *Humeralis* or the veine of the arme, becauſe by the arme it diſcendeth vnto the hand. It is alſo called the *Outward* veine, becauſe it runneth on the outſide of the Cubit. For paſsing along by the top of the arme it runneth vnto the cubit and the hand betwixt the fleſhy membrane and the coate of the muſcles, *Axillaris. Cephalica.*

and before it hide it hide it ſelfe vnder the arme it ſendeth out ſometimes one, ſometimes two little branches [dd] which are diſtributed through the muſcle of the arme called *Deltoides* and the skinne wherewith it is couered: then it paſſeth to the outſide of the Cubit in which very place ſome make the beginning of the *Cephalica* veine, and call that part aboue it the *Humeraay* veine. There alſo it is very conſpicuous euen without ſection, except the man be eyther too fat or haue ſmall veynes. But in the deſcent, there iſſue from it ſmall veynes as far as to the ioynt of the Cubit or the elbow, partly directly, partly creeping obliquely into the muſcles of the arme and into the outſide of the skin, ſo that ſometimes it ſeemeth to vnite it ſelfe [f] with the branch of the *Baſilica*, which is diſtributed likewiſe in the skin.

The diuiſion of the *Cephalica.*

Sometimes a branch is ſent to the inner muſcles of the Cubit, which branch in men is moſt commonly wanting: but when it commeth vnto the ioynt or bow of the Cubit, [f] it is diuided neare the externall protuberation of the arme into an inner and an outward branch.

The inner branch.

The inner at [h] being led along vnto the middeſt of the bent of the Cubit vnder the skinne ioyneth or vniteth it ſelfe with a branch of the *Baſilica* at [t] & ſo maketh that veine which is called *Mediana* or the middle veyne at [a]. But ſometimes this branch is ſcarce cõſpicuous, whereas the veyne oppoſite proceeding from the *Baſilica* is very manifeſt, and ſometimes it is quite contrary.

Mediana.

The veyne called *Mediana* [a] hath his name from his ſituation, and it is alſo called *Communis* or the Common veyne, becauſe it is formed of branches of the *Cephalica* and *Baſilica* running both into one [b] This coniunction is made commonly in the verye bought of the arme, ſometimes much lower not far from the middle of the length of the Cubit, and by *Auicen* is called *The blacke-veyne*. It runneth obliquely downward through the middle Region of the arme, and aboue the *Wand* ſprinkleth ſurcles on eyther hand, ſometimes alſo it aſſumeth others from thoſe which runne through the inſide of the Cubit. But aboue the *Radius* or *Wande* [below β] it is diuided into two [γ ε] branches. The vtter [γ] ſendeth a ſurcle marked with [σ] to the inſide of the wreſt toward the Thumbes, and is mingled with others. [q z] The remainder runneth out toward the Region of the thumbe and forefinger which ſome call *Saluatella*; but commonly the Chyrurgions call it *Cephalica* by others *ocularia*. The inner branch [ε] is ſpent in many ſurcles betweene the the fore and middle fingers, and ſome deale into the ring finger.

Some thinke this to be that which *Auicen* calleth *Syele*. But the truth is, that the diſtribution of the veynes which run vnder the skin of the hand is ſo diuers, yea in the Cubit it ſelfe, that the ſame mans right arme doth ſcarce agree with his left, but two men alike you ſhall not finde among a great many, and therefore their declination is harder to ſcore out.

The vtter branch. *Funis Brachij*

The vtter branch of the *Cephalica* by *Auicen* called *Funis Brachij*, the Chord of the arme [i] goeth obliquely by the *Wand* into the length of the Cubit on the outſide, ſprinkling ſmall veynes as he goeth [k] into the skin. But when it hath attained vnto the middle of the wreſt on th inſide neere to the *vlna* or *Ell* [l] there is ioyned to it a ſmal branch of the *Baſilica* [χ] wherewith being increaſed it climbeth ouer the outſide of the wreſt, & with a ſmall branch entangleth that part of the hand which lyeth before the ring and the little fingers, and maketh that veyne which the Arabians call *Syele*, we commonly *Saluatella*, which in the backe of the hand appeareth before the fingers. The ſection of this veyne in the left hand is held by the Arabians and by many other Practitioners in phiſicke to be of great auaile in melancholy diſeaſes. Sometime this branch of the *Cephalica* is wanting & his ſtead is ſupplied by a brãch of the *Baſilica* [χ] which runneth throughout the length of the Ell, ſometime it is ſupplied by branches iſſuing from the *Mediana* into the skinne.

Saluatella.

Baſilica.

The lower branch of the Axillary veine is called *Baſilica.* [Ta. 9. m m] It is greater and larger then the *Cephalica*, and deuided into more ſurcles, many call it *Axillaris*, the veine of the Arme-hole, ſome the *inner veine of the cubit*, becauſe it deſcendeth by the in-ſide of the cubit.

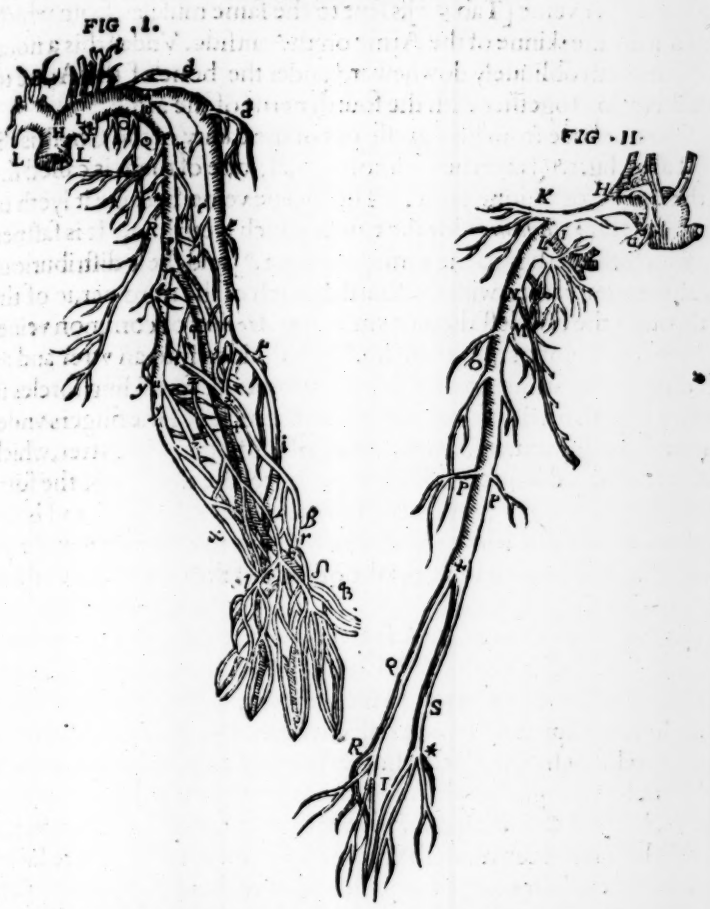
Hepatica.

Amongſt practitioners it changeth his name in reſpect of the Arme, for in the right arme it is called *Hepatica* or the Liuer-veine, becauſe it is opened in diſeaſes of the Liuer. In the left Arme it is called *Lienaris* or the Spleene-veine, becauſe it is opened in diſeaſes of the Spleene. It paſſeth along the inſide of the arme among the muſcles which compaſſe the bone, and at the Arme-pit is entertayned by many Glandules, where alſo it

Lienaris.

is

Table 9. Figure 1. sheweth the Cephalica *and* Basilica *Veins & their branches.* TABVLA IX.



H The by-partition of the hollow veyne vnder the breast-bone nere the *Iugulum*.

I, The subclauian veine, on either hand, aboue I the vtter and inner Iugular veine, with that which is called *Cernicalis* or the Neck-veine.

K, the vpper intercostall veine.

LL, the Mammary veine.

O. *Muscula*, which goeth to the lower muscles of the neck and the vpper of the Chest.

P, A vein which reacheth vnto the muscles that lie vpon the Chest vnto the skin of that place, and vnto the dugges.

Q, A veine that goeth vnto the backside of the chest to the hollow part of the blade & to the neighbor mu[illegible].

* Small veins to the glandules vnder the Arme-pits.

R, A branch distributed along the sides of the Chest, especially into the broad muscle.

a, the Humerary veine called *Cephalica*.

b, A branch vnto the backewarde muscles of the necke.

dd, Branches from the *Cephalica* to the muscle that lifteth vp the arme.

ee, Small veines out of the *Cephalica* dispersed through the skin of the arme, & the muscles that leade the arme backward.

f, A threefold diuision of the *Cephalica*. *g*, The first branch to the muscles arising out of the externall protuberation of the arme. *h*, A branch of the *Cephalica* which helpeth the *Median* veine. *i*, the third branch of the *Cephalica* running obliquely aboue the *Wand*. *k*, Surcles that run vnto the skin from this 3 branch. *l*, The third branch at the wrest ioyned with the branch of the *Basilica* noted with *x*, their coniunction is at *l*. *m*, The veine called *Basilica*. *n*, *o*. A branch running by the heads of the muscles of the cubite at *n*, also branches to the muscles themselues at *o*. *p*, A notable branch of the *Basilica* carried obliquely and accompanied with the fourth nerue. *q*, The diuision of the *Basilica* into two branches, and that which is noted with *q* is alwayes accompanied with an artery. †, The deepe branch of the *Basilica* bipartited or diuided into two. *r*, The other branch that goeth to the flesh and the skin. *s*, A branch of this to the skin of the arme. *t*, That branch of the *Basilica* which with the *Cephalicall* branch *h* maketh the *Median* veine at *cc*. *u*, A branch of the *Basilica* going to the inner head of the arme. *xx*, A braunch out of the former going to the wrest, and toward the little finger ioyning it selfe with the *Cephalica*. *y*, A branch nourishing the skin at the outside of the cubit. *zz*, The vpper z sheweth a propagation out of the branch of the *Basilica* marked with *t*. the lower z another out of the *Basilica* branch at *x* running to the inside of the arme. *cc*, The Common veine called *Mediana*. *β*, the partition of the *Median* veine aboue the wrest, but the *β* is set a litle too low. *γ*, *δ*, The outward branch heereof going to the outside of the hand at *γ*, from which ysseth a small branch vnto the inside of the hand at *δ*. z, Another branch towardes the middle and ring Fingers. *ζ*, The veyne of the Thumbe which nourisheth the Hillocke or mountenent which ioyneth with the veyne noted with *δ*.

is diuided into diuers propagations: the most noble whereof is disseminated into the muscles which lye vpon the chest, and of these againe the largest called *Thoracica inferior*, [Ta. 9.ᵏ] the lower chest veine, runneth neare the ribs and receiueth the rootes of those veines which yssue out of the chest, and whereby wee sayde before the distances betwixt the ribs were nourished: or to speake playner, the mouth of the veine *Azygos* doe ioyne in three branches sometime in foure on each side with the mouth of the chest-veine. Ta. 8.ˣˣˣ with ʸʸʸʸ.]

Hence any man may gather what veine is to bee opened in a *Pleurisie*, that is to say, whether the veine on the side inflamed or on the contrary side.

It

It ſendeth alſo a ſmall branch vnto the Muſcles which extend or ſtreatch the cubit, Tabl.9.[n] againſt which another veine is diſperſed from his oppoſite into the Glandules. From the ſame backeſide another veine [Tab.9.[o]]is ſent to the ſame muſcles, from which ſome ſurcles are ſprinkled into the skinne of the Arme on the outſide. Vnder this a notable propagation [Ta.9.[p]] runneth obliquely downeward vnder the bone of the Arme toward the outward protuberation together with the fourth nerue of the arme.

The diuiſion of the *Baſilica*

Afterward this *Baſilica* not farre from his egreſſe out of the cauity of the Cheſt, is diuided into two trunkes [Tab.9.fig.1.[q r]] and thoſe almoſt equall, one of them is called the Deep veine, the other the *Cutany* or Skinne veine. The Deepe veine becauſe it lyeth or

Profundus.

lurketh in the bottome is called *Profundus* [q]or the trunke which lyeth low. It is faſtned to the Axillary Artery which runneth into the arme[ta.9.fig.2.[s]] and their diſtributions are almoſt alike. It is alſo accompanied with the fourth branch of the third nerue of the arme, and deſcendeth through the middeſt thereof vnder the *Median* or common veine,

His diuiſion.

and when it hath ouercome the ioynt of the cubit;[t.9.*]it is diuided into an vtter and an inner brãch, which receding or departing a litle one from another, & ſprinkling ſurcles into the muſcles, do deſcend together with the tendons of the muſcles of the fingers vnder the tranſuerſe ligament, and are diſtributed into the inſide of the fingers. The vtter, which deſcendeth along the *Radius* or wand lendeth 2.ſmal branches to the thumbe & the forefinger, and one to the middle finger. The inner is tyed to the bone of the cubit and is deuided alſo into two; and from theſe one branch is afforded to the middle finger and 2.to the Ring & little fingers. The firſt to the muſcles of the outſide of the hand the 2.to thoſe on the inſide.

Subcutaneus.

The other trunke of the *Baſilica* [ta.9.[r]]is called *ſubcutaneus* or the skin-veine, becauſe it runneth immediately vnder the skin throughout the length of the arme on the inſide, and in his paſſage diſperſeth many branches; afterward a little aboue the inner protuberation of the arme where it is no leſſe conſpicuous before diſſection thē the *cephalica* is aboue the

His diuiſion.

cubit; it is diuided into a forebranch [ta.9.[t]]and a hinder branch.[t.9.a little aboue [u]]The fore branch running obliquely through the middle of the bought of the cubit, maketh together with the inner branch of the *Cephalica* [ta.9.[h]]vnder the bent, the Common veine. [ta.9.[a]]Yet ſometimes this branch which runneth vnto that common-veine is farre larger or leſſer then the branch of the *Cephalica*, ſometimes alſo either of them are double. The poſterior branch of the *Skin-veine* [ta.9.[u]] is diuided into two neare the inner protuberation of the arme, [vnder [u]]and the vtter and greater of theſe [x x] deſcendeth along the *vlna* or Ell vnto the wreſt, and ſendeth a branch downward [xx] neare the wreſt vnto the little finger, and againe meeteth and ioyneth [l] with another branch of the *Cephalica* [l]paſſing that way, and this after the manner we haue before ſpoken of is diſtributed into the outſide of the hand. From this branch alſo a ſurcle is diſſeminated vnto the skin [y]and the backparts. There are alſo other branches [the lower [z]]yſſuing out of this propagation [a] diſſeminated into the skin of the inſide, which branches are diuerſly mixed now vniting themſelues, againe departing one from another, aſſuming ſurcles from the propagation noted with [x]and communicating others vnto it.

Burſten veins in the arme.

Finally, from that branch of the *Baſilica* [Ta.9.[t]] which maketh the *Mediana* or common veine, out of the lower and middle part thereof yſſueth another notable veine[at the vpper [z]] which deſcendeth ſometimes directly ſometimes with a crooked paſſage vnto the wreſt, and is diuerſly vnited with other neighbour veines. Hence it is, ſayth *Veſalius*, (and the obſeruation was worthy of the Authour) that ſometimes the inſide of the cubit is troubled with broken or bodden veines as the calfe of the Leg is. The ſureles of that notable veine ſometimes directly or in a right line, ſometimes ouerthwart, ſometimes obliquely, ſometimes againe vnited and ſometimes diuided, doe growe vnto the skin of the inſide of the hand.

An idle curioſitie.

From theſe ſo diuers coniunctions of veines, eſpecially when the beginnings of the *Cephalica* and the *Baſilica* is one and the ſame [Ta.9.[m n] out of I] we may eaſily gather how vnprofitable a thing it is to be ſo ſcrupuluos and anxious in the choice of veines in one & the ſame ſide of the arme: wherefore when wee are reſolued to open a veine, and a veine of the arme, as alſo on which ſide it ſhall be performed, it will be out of doubt the beſt to ſtrike that veine which vpon the binding of the arme will bee moſt turgid and full. For there are three places to let bloud in the arme, according to *Galen* in his Booke *de curatione per ſanguinis miſsionem*, the interior, the exterior and the middle. VVherefore when

we

we come to open a veine we finde all three places equall or two only, or all vnequal: sometime also one of them is hidden and sometimes two. The section of the inner veine he esteemeth profitable for those that haue any affection in the lower parts of the neck. The section of the vtter veine when the superior partes as the face and the head are diseased. The section of the middle veine communicateth with both, for it is compounded of veines ysſuing on both sides. *Galen.*

To conclude, there are found in the *Cephalica* and *Basilica* certaine values, but I containe my selfe, for because we shall meet with them also in the Foote, I thinke it best to referre their description vnto the end of our discourse of the veines. The Values.

CHAP. X. *Of the Veines of the whole Foote in the large acception.*

THE hollow veine in the lower Belly descending vnto the Holy-bone, when it commeth vnto the fourth racke-bone of the Loynes, where it lyeth vnder the great Artery [Table.10.O] is deuided into two equall trunkes: one of which goeth to the right Legge, the other to the left, which trunkes before they get out of the *Peritoneum* are called *Iliaci*, Ta.10. betwixt O and G] and presently both the right and the left bones are subdiuided into two branches, [Ta.10. ρ ϛ] an interior and an exterior, from which diuers propagations are dispersed, as we haue before touched in the eight chapter of the third booke.

From thence it beginneth to be called *Cruralis* or the veine of the Leg, [Table 10. ε] and after the externall braunch [ρ] hath attayned with two boughes vnto the bone of the Legge. It passeth the share-bone [ϛ] and sendeth a surcle vnto the *Cup* of the Hippe to be disseminated into the Muscles of that place which compasse the inside of the Thigh, and so a branch of it runneth vnder the skinne of the Thigh on the same side. Presently after it is ioyned [χ] with the internall crurall branch [char.2.] and so ceaseth. But because in that place toward the lower part of the bought of the Thigh, there is a cauity wherein the braunch of the hollow veine was to bee deuided into many propagations, that those propagations might be more firmely secured, there are many Glandules disposed round about, which also are a defence to the Nerue and the Artery that descend that way with the Veine. *Cruralis.*

From the *Crurall* branch [tab.10 ϐ] which is the trunke of al the rest of the Veins that run into the Legge and ysſueth from the outward branch [tab.10, ϛ] of the trunke of the Hollow veine, there ysſue on either side six branches. Diuision of the crurall veine into six branches.

The first is called *Saphæna* or the branch of the *Ankle* [Θ] which is a notable and verie long Veyne. It runneth together with a Nerue fastned vnto it through the inside of the legge betwixt the skin and the fleshy panicle vnto the knee and so on towarde the inner ankle, and is diuersly diuided into the top of the foote towarde the Toes, especially toward the great Toe where it is mingled with other Surcles sent from other Veynes into that place. 1 *Saphenæ.*

From this branch commonly there are foure propagations sprinkled through the skin. The first is double, one interiour [Λ] which being yet in the groyne sendeth on either side branches to the inside of the Thigh, to the groine it selfe and to the rim of the belly. The other exterior [Ξ] and larger then the former, determining into surcles which are sent into the foreside and outside of the Thigh. 4 propagations.

The second propagation at the middle of the legge [Π] reacheth to the first muscle of the *Tibia*.

The third is rowled orbicularly backward at the knee, and one part of it goeth to the skin of the whirle-bone. [Σ] the other into the Ham: and this branch is altogether vvanting when the Veine of the Ham is a little larger then ordinary [Char.6] or if it bee not wanting it is exceeding small and slender.

The fourth departeth with surcles forward and backward at the middest of the *Tibia* [Tab.10 from ρ to Ψ] which surcles do diuersly vnite themselues with the Veines that are next vnto them, & are againe parted asunder. Sometimes from the inner part of the *Tibia* vnder the foreside of the Ankle it is reflected and runneth vnto the vpper side of the foote [Ψ] and is distributed almost into all the Toes of the foote; but the surcles aboue the foote and at the Toes doe differ much. For in some bodies it is mixed with other braunches, and runneth out vnto the little finger: sometimes it runneth towardes the Thumbe and the forefinger; wherefore scarse any man hath the same distribution of the

Veines

Table 10 *Sheweth the diſtribution of the hollow veyne into both the feete.*

TABVLA X.

O, The diuiſion of the hollow veyn at the fourth ſpondell of the loynes aboue the holy-bone into two Iliack trunkes, which diuiſion is like the greeke letter Λ.

σ *Muſcula ſuperior* diſſeminated throgh the muſcles of the loynes, of the *Abdomen* and the *Peritonæum* or Rim of the belly.

ρ σ, the byfurcation of the left Iliack trunke into an exterior branch at σ, and an interior at ρ.

τ *Muſcula media*, a propagation of the branch ρ into the outward muſcles of the thighes and the skinne of the Buttoeks.

χ, the meeting of the branch ρ with the veyne of the ſecond branch.

υ, the paſſage of the branch ρ through the hole of the ſhare-bone.

G, the Crurall veyne which is the ſtocke of the veynes that go into the leg.

Γ, *Epigaſtrica*, A propagation of the branch σ carried vpward to the muſcles of the *Abdomen*.

ΔΔ, *Pudenda*, A propagation of the branch σ, which runneth ouerthwart to the Genitals.

Θ, the veyne of the Ankle called *Saphæna*.

Λ, The interior branch of the *Saphæna* going to the inſide of the thigh, to the groynes & the *Peritonæum*.

Ξ, the vtter and greater branch of the *Saphæna* going into the fore-ſide and outſide of the thigh.

Π, the ſecond branch of the *Saphæna* to the firſt muſcle of the leg.

Σ, the third branch of the *Saphæna* rowled orbicularly to the backſide of the knee.

Φ, the fourth branch of the *Saphæna* which runneth vnder the skin through the inſide of the leg and is diſtributed into diuers ſurcles. And this branch may heere be opened.

Ψ, this branch ſhould haue gone downe as far as char. 7.

Ω, *Iſchias minor*, A propagation of the exterior branch σ vnto the muſcles that ſit vppon the ioynt of the hippe and to the skinne of that place.

1, *Muſcula*, the vtter and leſſer branch heereof runneth vnto the 2 and 4 muſcles of the leg. 2, the inner and greater branch of the *Muſcula* diſtributed through the muſcles of the thigh, eſpecially the fift & the third of the leg. 3,4,5, Two crurall branches 3,4, meeting together; ſurcles paſſe at 5 backward to the skin of the thigh, and deſcende through the middle of the Hamme. 6, *Poplitea*, the hamme-veyne, which veyne the Antients did often open. 7, Small branches from the hamme veyne which runne through the skin of the Calfe vnto the heele. 8, *Suralis* or the Calfe-veyne. It is diuided at the lower ſide of the thigh into an exterior trunke, 9, and an interior, 14. 9,10, The vtter branch of the ſural veyne at 9, diſtributing a ſmal branch outward into the skin of the knee. 11, the diuiſion of the externall ſurall branch vnder the knee into an inner brãch 11 going betwixt the muſcles of the foot. 12,13, And an vtter which runneth throgh the outſide of the leg vnto the outward ankle & the vpper part of the foot in diuers ſurcles. 14,15,16, the inner ſural branch 14 running through the backſide of the leg, a branch of the ſame through the inſide of the leg at 15, which deſcendeth to the heele and the great toe at 16. 17,18, *Iſchias maior* iſſuing from the inner branch of the ſurall veine at 14, and paſſing vnto the muſcles of the Calfe. From this a great branch 18 is diſtributed into the vpper ſide of the foot and the toes paſsing downeward betwixt the muſcles of the leg. 19, The remainder of the inner trunk, 14 which runneth behind the inner ankle, and is conſumed into the toes. 20, The coniunction of the externall ſurall branch with the branches of the *Poplitea* or the hamme veine.

veynes in both his feet, the ſame number and the ſame magnitude.

This veyne Phyſitions vſe to diuide in the diſeaſes of the wombe, eſpecially in the retention of the courſes about the ankle.

The ſecond branch of the Crurall veyne is called *Iſchias minor* [Tab. 10, Ω] and is oppoſite to the former, for as that is the inner branch of the Crurall trunke, ſo is this the exterior.

terior. It is but a ſhort veyne and is diſſeminated outward and ouerthwart into the fore-skinne of the ioynt of the hip and to the muſcles of that place.

Afterward the trunke it ſelfe paſsing from the groyne is drenched among the muſcles which compaſſe the bone of the thigh, and ſhooteth out of it ſelfe the third veyne

The third veyne is called *Muſcula*, [Tab.10, char.1.] and is double, ſometimes they anſwere one another. The vtter and leſſer of theſe [char.1,] parteth with ſurcles to the ſeconde and fourth extending muſcles of the *Tibia* and into the skin. The inner and the greater [char.2,] which alſo lyeth deeper, is diuaricated or diuerſified through all the muſcles almoſt of the thigh, eſpecially the fift and the third extender of the leg, and at length aſſumeth the end of that veyne [u] which runneth through the hole of the ſhare bone into the thigh, wherewith being increaſed, but lurking ſtil betwixt the muſcles it deſcendeth vnto the knee. But the greateſt veyne called *Cruralis* [°] in the middle of the thigh, is by degrees writhen backe-ward and offers ſmall ſurcles to the membranes of the nerues that deſcend vnto the leg. Afterward it parteth with the fourth veine. *Muſcula.*

The fourth veyne is called *Poplitea* or the Hamme-veyne, which is made of two crurall branches vnited, [char.3,4,] From this in his originall, certaine ſurcles are ſent backward and vpward into the skin of the thigh, [char.5,] afterward it falleth directly vnder the skin through the middeſt of the bent of the hamme [char.6,] as farre as to the heele. [char.7, the lower] Sometimes it deſcendeth to the skinne of the outward ankle, ſometimes alſo of the inner, from which in his progreſſe he ſprinkleth many ſmall branches vnto the skin of the Calfe, ſome right, ſome oblique and ſome tranſuerſe vnequally commixed & vnited together. Sometimes wee meete with it ſimple and ſingle, and ſometimes this *hamme-veyne* [char.3,] aſſumeth vnto it ſelfe a branch from the veyne which is ſent to the fift muſcle of the thigh, [char.2,] and being ioyned therewith it runneth out into the skin on the back ſide of the thigh, and ſendeth ſome ſurcles vpward. And this is the veyne which the Ancients vſed to open vnder the knee. The fift veyne of the Crurall branch is called *Suralis* or the Calfe-veyne. The great veyne of the legge at the lower end of the thigh, after it hath ſent ſmall branches back-ward on eyther ſide, [at char.8,] into the originall of the three muſcles which make the Calfe, it is in the hamme diuided into an exterior and an interior trunke. The exterior [character 9] after it hath diſtributed a branch [character 10,] obliquely outward toward the connexion of the *Brace* with the *Leg*-bone into the skinne on the fore-ſide of the knee, is preſently vnder the knee diuided into two branches; an interior [character 11,] which deſcendeth with the Brace among the muſcles of the foote, and it endeth where their fleſhy part determineth, for it attaineth not to the skinne; and an exterior, [character 12,13,] which running along the out-ſide of the legge to the outward ankle and the vpper part of the foote attaineth to the skinne, but the skin on the outſide. *Poplitea.* *Suralis.* His diuiſion. The exterior diuiſion.

It diſtributeth alſo (as did the *Poplitea*) [char.7,] diuers ſurcles, and mingling it ſelfe [character 20,] with the ſurcles of the *Poplitea*, eſpecially in the toppe of the foote which they call the *Backe*, it maketh that knarle of veynes which is ſeene in the vpper part of the foote vnder the skinne.

The Interior [character 14,] deſcending directly through the backſide of the legge looſeth a branch [character 15,] from his inſide, which paſsing along by the inſide of the *Tibia*, is diſſeminated vnder the skin vnto the inſide of the heele and the great toe, [char. 16,] and is vnited to the ſurcles that are there-about, and afterward againe diuided from them as we haue ſaide before that other veynes do. The interior.

And this ſurely is the reaſon why in this part ſo often there are *Varices*, that is, burſten or bodden veynes. But this vnion and diuiſion or diſtraction afterward of the veynes was neceſſary, leaſt when the skinne is offended and ſome veynes cut ouerthwart the skin that bordereth vpon it ſhould be deſtituted of nouriſhment. Wherefore becauſe in the legge in three or foure places the internall veynes are vnited with the cutany veynes or veynes of the skinne, eſpecially in the foote if you purpoſe to open one of them that lye next vnder the skinne there is no reaſon you ſhould be very ſcrupulous in your choice, as if they were peculiar veynes derined from diuers parts or bowels of the body, for they are all propagated from one and the ſame trunke. Note this.

The Interior trunke [char.14,] when it hath ſent foorth the fore-ſaide branch, [char. 15.] runneth deepe and produceth the ſixt veyne.

The ſixt and laſt veine is called *Iſchias maior*, [char.17,] the greateſt part wherof deſcen- *Iſchias maior.*

ding

ding through the Muſcles of the Calfe caſteth on each ſide ſmall ſurcles, and when it attaineth to the ſeparation of the bones of the leg from the Brace-bone, it ſhooteth out a great propagation [ch. 18] from his forepart, which hauing perforated the membranous Ligament runneth among the Muſcles which occupy the forepart of the *Tibia*, and in his deſcent affoordeth ſurcles to the neighbor-muſcles; and when it is paſt vnder the tranſuerſe ligament is diſtributed in the vpper part of the foote, but ſo as it is diuided into his Muſculous ſubſtance, and ſo giueth to each toe two ſmal branches. And this veine in the Sciatica and other affections of the Hip is vſually opened about the outward ankle; and *Falopius* giueth vs his word, that it is of great auaile though he relye more vppon experience then vpon any great reaſon.

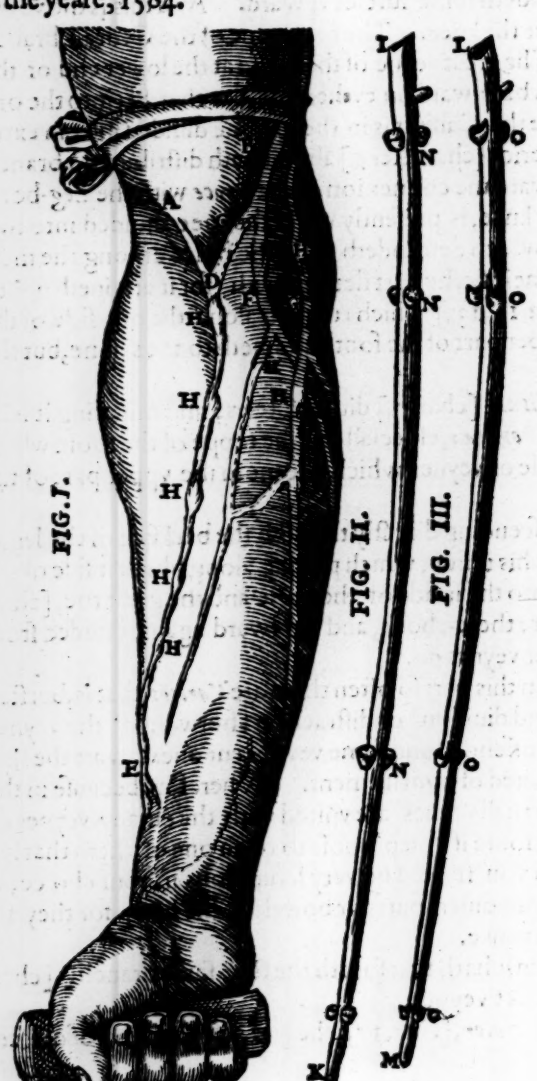
That which remaineth of the interior branch [char. 14] runneth into the backeſide of the foreſaid muſcles and ſo attaineth to the ſole of the foote, where it is conſumed into many ſmall branches which run by courſes. Two of them creepe along the inſide of each toe, ſometimes the little toe hath fiue, the next to it two, the middle toe one.

And thus haue we brought to an end the Hiſtory of the veines thoroughout the vvhole body. Now we ſhould paſſe on vnto the arteries, ſauing that wee promiſed in the end of the laſt chapter to ſay ſomewhat of the values which are found in the veines, which promiſe I will now acquite my ſelfe of.

CHAP. XI. *Of the Values or Flood-gates of the Veynes.*

Auicen. *Aquapendens.* *Salomon Albertus.*

OF theſe Values *Auicen* the *Arabian* ſeemeth to haue made the firſt mention, calling them *Cels in the Veynes*. *Hieronimus Fabritius ab Aquapendente* an excellent Anatomiſt of *Padua* in *Italy* made publique demonſtration of them in the yeare of Grace 1574. and wrote a Tractate of them in the year 1603. *Salomon* alſo *Albertus* ſhewed them in the yeare 1579. and wrote of them in the yeare, 1584.



Tab. xi. Figure. 1. ſheweth the arme bound ready for blood-letting.
Fig. 2 & 3. ſheweth two Veines of the legs turned the inſide outward.

A. A branch of the *Cephalica* Veine making the *Median* veine.
B, C. The *Baſilica* B and a braunch of it making the *Median* at C.
D. The *Median* Veine made of the branches of the *Cephalica* and *baſilica*.
E. The *Median* Veine being caried through the middeſt of the Cubit diuided aboue the *Radius*.
F. A deepe trunke of the *Baſilica* or the trunke lying very low.
G. The trunke of the *Baſilica* lying vnder the skin.
HHH. Values in the veines of the arme.
I, K. The firſt veine of the Leg.
L, M. The ſecond veine of the leg.
NNN. The values filled with bumbaſt.
OOO. The values empty.

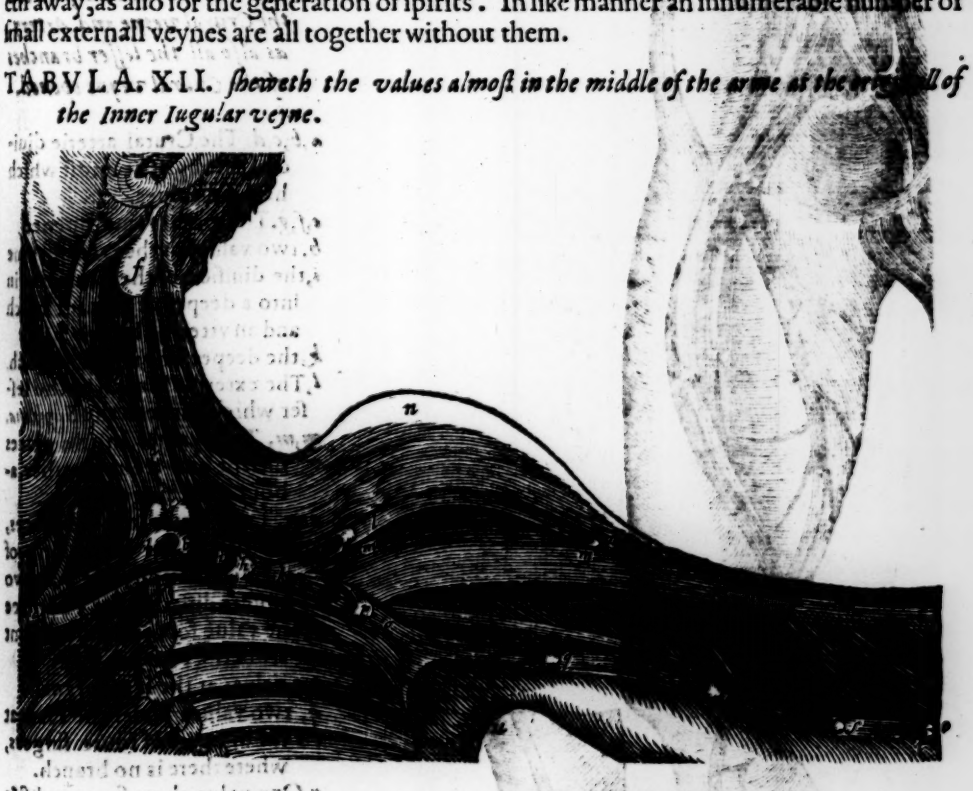
The Values are found in the Veines of the ioynts, and are nothing else but small portions of the coate of the veines starting in their cauity, and intercepting the one halfe thereof, making in them as it were an angle or corner: wherefore the body of the veine is no where so thin as where these small membranes do depart from it. Some men had rather call them *Ostiola* then *Valuulæ*, which word we do not better know howe to English then to call them *Floodgates* which stoppe and intercept the currents of waters. What a value is.

They are seated in the veines of the armes and the legges aboue and below after the Glandules of the arme-pits and the groine. Presently vnder the originals or out throtings of the branches which are disseminated from the sides of the veins into the neighbor parts for their nourishment. And the reason why they were created was, that the blood which is to be distributed to other partes, might in that place make a stay and not be carried in a full streame along the large or direct Canale or pipe, and from the lesser branches, and those that are propagated obliquely be defrauded. Their situatiõ. And vse.

They reach from the sides of the veynes vnto the middle of their capacity: neither do they shut vp the orifices of the braunches where they take their beginning out of the hollow veine, but are rather disposed in the branches themselues, for otherwise there could haue bene no regurgitation of humors which is very necessary as wee are taught by reuulsions. But in the orifice of the Iugular veine there are found two Values, least when the head is reclined too much backward the blood should violently rush into the braine. Where they are found.

The Trunke of the Hollow-veine in the lower and middle Region, as also that of the Artery hath no Values, that without any obstacle or opposition the blood might bee euery way distributed as well for the restauration of the substance that vanisheth or wasteth away, as also for the generation of spirits. In like manner an innumerable number of small externall veynes are all together without them.

TABVLA. XII. *sheweth the values almost in the middle of the arme as the originall of the Inner Iugular veyne.*



a. The subclauian veyne.
b, The orifice of the veyne betwixt the inner Iugular and the Axillary veyne.
c, Two values at the originall of the internall Iugular.
d, The internall Iugular opened.
e, The diuision thereof nere the head.
f. The Glandule vnder the eare.
g,g,g, fiue ribs cut off.
h, Values at the Axillary veine.
i. The axillary veine produced from the Subclauian.
k. The diuision of the axillary vein into the *Cephalica* and the *Basilica*.
ll, The *Cephalica* called also *Humeraria*.
m,m Two values in the *Cephalica* fiue fingers almost asunder.
n. The muscle of the arme called *Deltois*.
oo, The *Basilica* veine called also *Hepatica*.
p,q,r,s. Foure values, the first is foure fingers of the second, the second three from the third, the third two fingers off the fourth.
t, Two values ioyned together in the *Basilica*.
u, The Arme-pit or the hole vnder the arme.

The number of theſe Values is vncertain and the diſtances betweene them very vnequal, yet commonly they are double or two together, vnleſſe it be little aboue the Tranſuerſe Ligaments which containe the Tendons of the hands, the foete, the fingers & the toes. Alſo when a large veine beginneth to be contracted there moſt commonly they begin to be fewer till at length they vaniſh quite away. For where it is fit that more blood ſhould be ſtopped and ſtopped longer there are two Values; where leſſe and for a ſhorter time there one wil ſerue the turne eſpecially there is but one where a leſſe veſſel is obliquely produced out of a greater.

Their diſtáce. For the diſtance betweene them, although they runne throughout the length of the veſſell, yet in ſome places there is two fingers, in ſome three, in ſome foure, in ſom fiue fingers diſtance between them. As for example, in the *Cephalica* vnder the Muſcle called *Deltoides*, there are two Values about fiue fingers diſtant one from another. In the *Baſilica* as it runneth through the inſide of the arme there are foure large Values. The firſt is foure fingers diſtant from the ſecond, the ſecond three from the third, the third two from the fourth, after which follow two ſmall Values ioyned together.

In the *Cephalica.*

In the *Baſilica*

So in the foote (I meane the foote in the large acceptation) in the Hollow veyne before it be ſubdiuided in the groine there are two great values ſet, afterwards when it is diuided into a greater and a leſſer trunke, the greater in two places hath two values foure fingers diſtant one from another. Thence downeward at the Ham one, at the calfe two, then one, and finally two other. But in the leſſer trunke there are more, for in the beginning of the byfurcation there are values; within the diſtance of two fingers two more;

In the Veines of the Foote.

TABVLA. XIII. *ſheweth the Crural veine and Artery, as alſo all the leſſer branches of the Crural veyne opened.*

a,b,c,d. The Crural arterie diuided through the midſt which hath no values.
e,f,g. The crural veine opened.
h. two values in the crurall veine
i, the diuiſion of the crurall vein into a deeper or greater brãch and an vtter or leſſer.
k, the deeper or greater branch.
l, The exterior branch or the leſſer which maketh the *Saphæna.*
m,m, Two values in two places diſtant one from another about foure fingers.
nnn, Two values in three places, the firſt in the beginning of the bifurcation, the 2 at two fingers diſtance, the 3 at three
o, one value foure fingers diſtant from the two laſt.
p, 2 values at the Ham branch.
q, two values vnder the Ham at the diſtance of foure fingers, where there is no branch.
r, One value, three fingers diſtãt from the former.
, One other value foure Fingers diſtant from that.
t,u. The veine *Saphæna.*
x, A value 5 fingers diſtant from the former.
y, 2 values at the wriſt of the foot
z, A value three fingers diſtant from the former.
a, The laſt value of the *Saphæna,* for that which remaynes hath no Values at al'.

and two and

others three fingers off; likewise in the same veine making the *Saphena* there is one value; foure fingers off of that two, and vnder the hamme foure fingers off likewise two more; three fingers off these there is one, and another foure fingers off it; fiue fingers off that another, two vnder the wrest of the Foote; three fingers off them one single one, and after the same distance appeareth the last; the remainder of the *Saphena* runs without values vnto the top of the great Toe.

Their position

But because the stronger current and course of the bloud might bee better abated, these values are not placed in a right line or alwayes on the same side, for then the whole streame of bloud would haue flowed downe that side of the vessell that is free: Wherefore they vary their seate very artificially, as if in the vpper part of the veine there be two values, then after the distance which wee sayde was betweene them, other two values appeare in the lower part of the veine, so that the hornes of the following membranes doe regard the middle and embowed part of those that went before and on the contrary, yet so that in the middest they doe not touch one another, but leaue a tract or path whereby the bloud may passe downward and fall as well into the lower values as into those aboue. So then the lower values stay that bloud which escapeth from the vpper, & yet the course of the bloud is not intercepted.

Their figure.

The figure of a Value sayeth *Aquapendens*, is like the nayle of a mans finger, or they be like a horned Moone, on their outside they represent the knottes that are in the branches of plants, for when a mans arme is tyed to let him bloud, there appeare within certaine distances as it were knots on the outside, and in clownish bodies sayth *Hamme*, they may be seene to swell in the outside of the Legges like a *Varix* or a bursten veine. And truely a *varix* is nothing else but a veine and his value dilated by thick bloud which is detayned in the value, for without these the veines would bee dilated and swell equally in euery place.

Vpward toward the rootes of the veines these values are open, but below and at the sides they grow to the veines, for they are portions of their coate. And if you put a quill

Table 14. *sheweth the values of the Crurall veine and his deep branch which walketh along with the Arterie, and these values may here be seene as far as the bifurcation.*

TABVLA XIIII.

b, The deeper braunch of the *Crurall* veine which must bee tyed with the branch marked with K in the former Table about *d*, which noteth the artery.

d, The *Crurall* artery which must bee ioyned with *d* of the former table.

g, Two values with a propagation out of the veine.

i, The hamme.

l, one great value with a propagation.

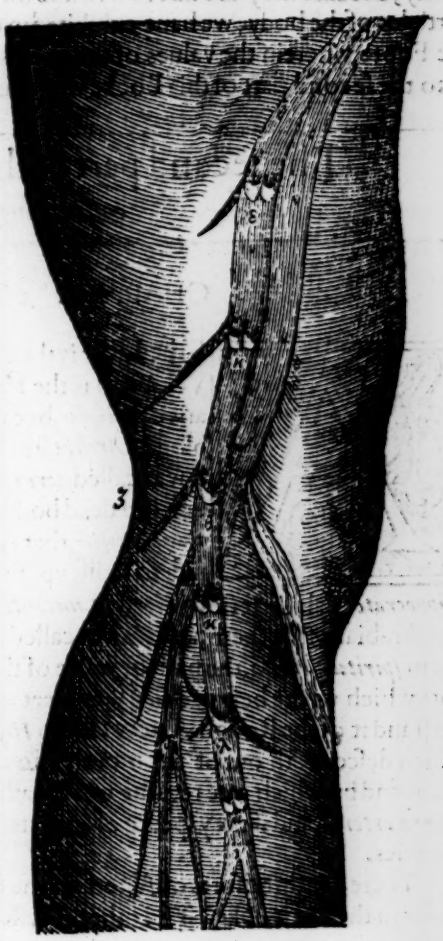
m, The Calfe.

n, Two values without any branch.

o, One value with one propagation on either side.

p, Two values without propagations.

r, The *Crurall* veines, and the subdiuision of his deeper branch into 2, which also haue their values though wee cannot nowe follow them.



into a veine and lightly blow, then will the value ſwell out like a little bladder, or rather if we may compare little things with great, like the ſayle of a ſhippe when it runneth freſhly before the winde.

Their ſubſtance. Their ſubſtance is exceeding thinne that they might take vp the leſſe roome, yet very thight and faſt for more ſtrength that they might not be broken by the violent incurſion of the bloud.

Their vſe. Their vſe is to ſtay the bloud from falling too haſtily into the lower parts, otherwiſe becauſe the ioyntes doe hang downewarde the bloud would haue falne into them like a ſtreame, and ſo the lower parts ſhould haue beene oppeſſed by too great an affluence of Aliment, and burdened with a weight of humour, but the vpper parts ſhould haue been defrauded. Nowe by reaſon of theſe values the Aliment doeth ſubſiſt or make ſtay in the greater veſſelles as it were in a fountaine, that the ſmaller veines might alwayes haue nouriſhment at hand to conuay vnto their particular parts.

Againe, becauſe the veines were created not onely to deriue or tranſport the bloud into the parts, but alſo to adde ſomething vnto the perfection of his concoction, there is no doubt but theſe values were ordayned to ſtay the courſe and violence of the bloud that the veines might haue time to beſtow their trauell vpon it.

Thirdly they adde ſtrength vnto the veines, for were it not for theſe, it is likely that where a *varix* hapneth, there either the veine would breake, or at leaſt the dilatation be much more offenſiue. For becauſe the veine is of a membranous, ſimple and thinne ſubſtance it may eaſily be ſtreatched or broken.

Fourthly, when we exerciſe our ioynts vehemently and often, the heat of the parts is ſtirred vp and the bloud partly diſturbed partly called into the ioints, where the values do breake the force of it and ſo keepe it from miſchiefe.

Finally, if it were not for them in thoſe violent motions of the ioynts, the whole maſſe almoſt of bloud would be called into the armes and the Legs, and ſo the principall parts or bowelles of the body bee defrauded of their allowance; and thus much of the Values. Onely, becauſe they are not ſo well knowne nor ſo ordinarily demonſtrated as the other particles of the body, we haue exhibited in this Chap. 4. tables. Two of the Hand and 2. of the Foote, wherein the values of the veines are very liuely deſcribed; and ſo we proceed vnto the ſecond part of this Booke which is concerning the Arteries.

The ſecond part of the Eleauenth Booke *concerning Arteries.*

CHAP. XII. *Of the Arteries in generall.*

The names of an artery. AS the Liuer is the beginning of *Radication* and *Diſpenſation* to the Veines, ſo is the Heart to the Arteries. This Artery the Grecians call ἀορτὴν, becauſe it is as an Arke or Conceptacle of arterial bloud. *Ariſtotle* in his third Booke *de hiſtoria* [illegible]*malium* thinketh it was called *aorta*, becauſe his neruous part n[illegible] perceiued euen in a dead body; others thinke it was calle[illegible], παρὰ τὸ τὸν ἀέρα τηρεῖν, that is, to draw ayre. Others π[illegible] which ſignifieth to lift vp, for in their dilatation th[illegible] themſelues, *Hippocrates* cals Arteries φλέβας, but *micantes*, that is, beating v[illegible] manner did the Arabians ſtile them, and *Auicen* calleth them *venas audace*[illegible] *Pliny* calles them *ſpiritus ſemita*, the path or walke of the ſpirites. Wher[illegible]y of the Ancients which wrote before *Galen* you meet with the word Arte[illegible]en muſt you vnderſtand it of the Rough Artery: for ſo *Hippocrates*, *Plato*[illegible]did call that pipe which deſcendeth out of the mouth into the Longues, and [illegible]ſpirated ayre into them and by which wee returne our breath out. But *Galen* and t[illegible]ſe after him called it *aſpera arteria*, and if they ſpeake of an Artery ſimply, we muſt vnderſtand it of the ſmooth Arteries.

3. ſorts of arteries. There are three ſorts of Arteries: the firſt is called the *Rough Arterie*, of which wee ſpake in the ſixt Booke. The other is called the *Venall arterie*, of which alſo wee ſpake in the

the history of the heart. The third is called the great artery, which is the subiect of our discourse at this time.

Wee consider it therefore as it is Similar and as it is Organicall. As it is similar it may bee defined *A Colde and dry part engendred of the slimy part of the Seede*. Colde it is of his owne Nature, for by cuent it is most hot in respect of the blood and Vitall Spirits therein contayned. It is drie, lesse drie then a Tendon, and more dry then a Nerue. An arterie as it is similar.

But against this it may bee Obiected, that *Galen* in his second Booke *ad Glauconem* sayth; *That Nerueous parts require more drying then Arteriall and therfore are dryer then they*. Obiection.

I answer, that by nerueous parts in that place he doth not vnderstand nerues properlie so called, but nerueous bodies as Ligaments and Tendons. Solution.

If wee consider an Artery as it is an organicall part, it may be sayde to be a common instrument of the bodie, long, rounde and fistulated compounded of two peculiar Coates, intertexed or wouen with fibres, receyuing and contayning Bloode and Vitall Spirits laboured of a permixtion of Blood and Aire in the left ventricle of the hart, which also it conueyeth vnto all the parts of the bodie, together with heat to sustayne their life. As Organical

The substance thereof is membranous or nerueous that it might better be extended or compressed which conformation was more necessary for Arteries then for veins because of their motion. The substance

The coats are one outward which is thin, rare and soft like the coate of a veyne, wouen with many right fibres and some oblique, but none transuerse. Another inward fiuefolde thicker then the former, fast and hard, partly that the arterial and spirituous blood which is thin, pure and vaporous, and the vitall spirit might not exhale or vanish away, partlie that by reason of his continuall *Diastole* add *Systole* which it receiueth from the Heart as from a beginning of dispensation it might not be broken. It is also full of transuerse fibres the better to distribute the blood and vitall spirit to the whole body in his action & motion, for the inner coate onely of the arteries hath these transuerse fibres. To these two coats *Galen* addeth a third in the fift chapter of his seauenth booke, *De administrationibus Anatomis*. which some say is produced from the coate of the heart. It is in the inner surface of the vessell much like a Cobweb and most conspicuous about the productions of the greatest arteries. Coats.

Moreouer, they receyue a common and fine membrane in the lower belly from the Rim, in the Chest from the *Pleura* which couereth them, firmeth them, or tyeth them to the neighbour-parts, yet those arteries which run through the bowels haue not this coat.

The great artery is sometime called simply *great*, sometime the *greatest*, sometimes the *thicke* artery, sometime *Aorta* and is indeed the mother of all the rest of the Arteries, (except the Rough artery and the venall and vmbilicall arteries) being like a trunk or body of a tree, out of which all the branches do yssue. It was engendred, saith *Bauhine* out of *Galen de formatione fœtus*, before the Heart was formed and hath one principle of Originall, that is, the seede out of which it is immediately made as beeing engendred at the same time with other spermaticall parts. Another of Dispensation and Radication which is the heart or the left ventricle thereof, out of which it yssueth with a patent or open Orifice, whereby it receyueth from the heart in his contraction Blood and vitall spirites together with heate to be transported to the body. But because in the dilatation of the hart this blood and these spirits should not returne againe into the ventricle, there are placed in his orifice three values yssuing from within outwarde, as also there are in the arteriall veine. But these of the artery are stronger and greater, because the body of the arterie is harder then that of the arteriall veine. The great arrery. His originals Values

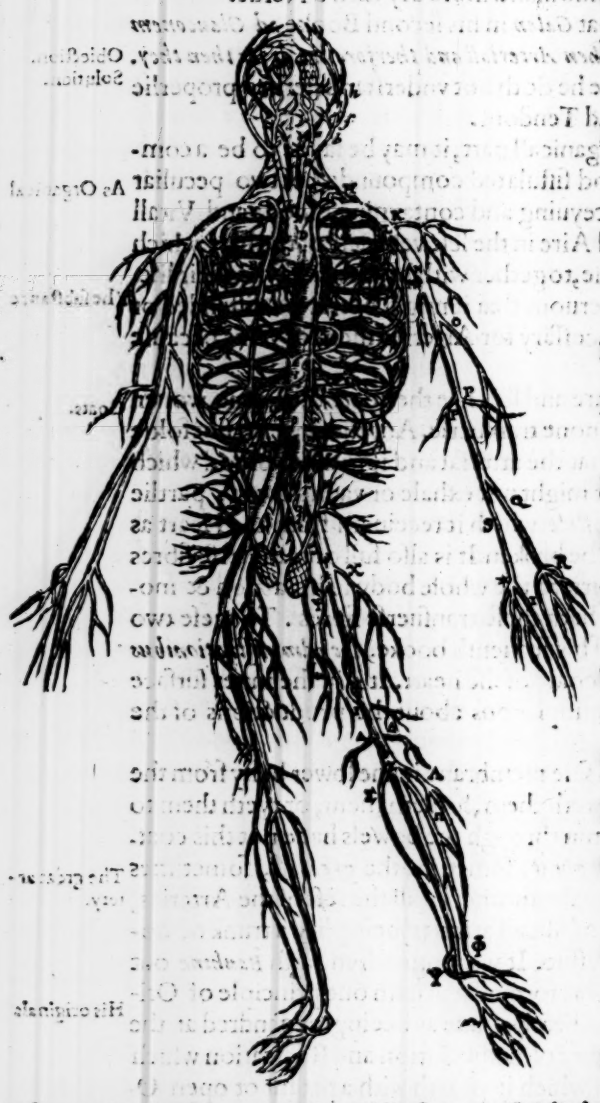
These values also doo hinder the aliment which is drawne by the Meseraicke arteries from the guts, that is the Chylus, which *Hippocrates* in his Booke *De Corde* cals *Alimentum non principale* as if he shold say an aliment at the second hand, lest I say, this Chylus shold get into the Heart. The Orifice also of this artery is established with a hard substance which is sometimes gristly, in some greater creatures a bony gristle, for it is very rare if it be found a true bone, notwithstanding that *Galen* saith it is a bone in an Elephant, but in man there is no such thing found. Hippocrates

The branches of this great Arterie are distributed into the whole body, as may appeare by this Table which we haue heereto annexed.

In this distribution of the branches of the great Artery they accompany the branches of the Gate and the Hollow-veynes, yet are their propagations not so frequent, be-

Tab. xv. sheweth the great Artery whole, and separated from all the parts of the body together with his diuisions and subdiuisions.

TABVLA XV.



A. The orifice of the great Artery, or the beginning thereof, where it yſſueth out of the heart.

B. *Coronaria*, ſo called becauſe like a crowne it compaſſeth the baſis of the heart.

C. The diuiſion of the great Artery into a trunke V.

D. The left ſubclauian climbing obliquelie vpward vnto the ribs.

E the vpper intercoſtal artery, or a branch which beſtoweth foure propagations vnto the diſtances of the lower ribs.

F, the necke artery which through the tranſuerſe proceſſes of the racbones of the neck, attaineth to the ſcul beſtowing ſurcles vnto the marrow and his neighbour muſcles.

G, the left Mammary artery running vnder the breſtbone, and to the nauell. It diſtributeth ſurcles to the *Mediaſtinum*, the muſcles of the breſt, and of the *Abdomen*.

H, *Muſcula*, or a branch attaining to the backward muſcles of the necke.

I, The *Scapular* arteries which goe vnto the hollowneſſe of the blade and the muſcles that lie thereon.

K, *Humeraria* which climbeth ouer the toppe of the ſhoulder.

L, *Thoracica ſuperior* ſprinkled vnto the forward-muſcles of the Cheſt.

M, *Thoracica inferiour*, which paſsing along the ſides of the Cheſt, attaineth to the *broad* muſcle of the arme.

N, the Axillary artery running out into the arme and affoording braunches vnto the muſcles thereof.

O, A branch reaching to the outſide of the cubit and lying deepe.

PP, Branches to the ioynt of the cubite with the arme.

Q. The vpper branch of the artery running along the *Radius* and offering ſurcles to the thumbe, the fore-finger and the middle finger.

k, A ſurcle creeping vnto the outſide of the hand and led betwixt the firſt bone of the thumb & that of the After-wriſt ſupporteth the forefinger where we vſe to feele the pulſe.

S, The lower branch of the Artery running along the *Vlna* and communicating ſurcles to the little finger, the ring finger and the middle finger. * A little branch vnto the muſcles about the little finger. T, the diſtribution of the vpper and lower branches into the hand and the fingers. V, the trunk of the great artery aſcending to the *Iugulum*, and the diuiſion thereof in that place into X, Y. Z. X, the lefte *Carotis* or ſleepy Arterie. Y *Subclauia dextra* is diuided into branches as the right is diuided. Z, *Carotis dextra* called alſo *Apoplectica* and *Lethargica*. *a*, The diuiſion of the left *Carotis* in the chops. *b*, the exterior branch of that diuiſion going into the face, the temples and behinde the eares. *c*, the inner braunch going to the throttle, the chops and the tongue. *d*, the diuiſion hereof at the baſis of the ſcull into two braunches which enter into the *ſinus* of the *Dura mater*. *e*, A propagation of the branch *b* vnto the muſcles of the face. *f*, the diſtribution of the branch *b* vnder the roote of the eare. *g*, the fore-branch hereof creeping vp the Temples. *h*, the backbranch running on the backſide of the eare vnder the skin. *i*, the trunke of the great Artery deſcending vnto the ſpondels of the backe. *kkk*. The lower *Intercoſtall* arteries which go vnto the diſtances of the eight lower ribs, from which are offered ſurcles to the marrow, and to the muſcles that growe to the backe and to the Cheſt. *l*, the artery of the midriffe called *Phrenica* or *Diaphragmatica*. ζ, *Meſenterica Superior*. but you muſt note that aboue ζ, the trunk of the *Caliacal* artery is taken away, leaſt the multitude of Letters in ſo ſmal a table ſhould breede obſcurity. *n*, θ, The right and left emulgents running from the *Aorta* or great Artery vnto the kidneyes. *u*, *xx*, The ſpermaticall arteries on either ſide going to the teſticles. λ, the lower Meſenterical artery on the left hand below μ running eſpecially into the Collicke gut on that ſide. μ.μ. The arteries called *Lumbares* which run ouerthwart and like knees affoording ſurcles to the muſcles that grow to the Loynes and to the *Peritonæum*. μ the lower; *Muſcula Superior* running into the ſides of the *Abdomen* and the muſcles.

ππ The

ρ The bifurcation of the great artery into two *Iliacke* trunks, and at the sides but somewhat inward are branches which make those that are called *Sacra*. τ the diuision of the left *Iliacke* trunke into an inner branch at ξ and an vtter at φ. ξ The inner *Iliacke* branch. φ *Musculi inferior*, the vtter propagation of the inner branch going vnto the muscles which couer the hanch bone and the *Coxendix*. π *Hipogastrica*, the inner propagation of the inner branch going to the bladder, the yarde and the necke of the wombe. ρρ The vmbilicall artery. σ The remainder of the branch ξ assuming an addition from the vtter branch neare φ and so falling through the hole of the share bone into the Leg. τ *Epigastrica*, it ascendeth vpward vnto the right muscle of the *abdomen*, and about the nauell is ioyned with the mammary artery. υ *Pudenda*, it creepeth ouerthwart the share bone. φ The *Crurall* trunke without the *Peritoneum*. χ *Musculi cruralis exterior* going into the fore muscles of the thigh. ψ *Musculi cruralis interior* going vnto the muscles of the inside of the thigh. ω the coniunction of this artery with the branches. Γ *Poplitea*, going to the muscles on the backside of the Thigh. ΔΔ which communicateth small branches to the ioynt of the knee and the muscles that make the calfe of the Leg. Θ the diuision of the *Crurall* artery vnder the hamme into three brauiches. Λ *Tibiæ exterior*, it accompanieth the *Brace* bone and is consumed into the muscles. Ξ the chiefe part of the crurall artery. Ξ the vpper and backer *Tibiæ*. ΠΦ The lower and backer *Tibiæ* running vnto the vpper side of the foote at Φ. Ψ A propagation of the crurall artery going to the inner and vpper side of the foot and sprinkling a branch vnto the ankle. Ω A propagation vnto the lower part of the foote which affoordeth surcles to each Toe.

cause the Artery doeth not alwayes accompany the veine, for those veines that goe vnto the skin haue no arteries with them, at least that are conspicuous. Againe they are very rarely disseminated into the muscles, but creepe onely on their outsides, because the thin bloud of the arteries and their subtle spirites when they yssue from them, are able to insinuate themselues farre into the substance of the part without the helpe of a vessell. The arteries why fewer then the veines.

CHAP. XIII. *Of the vse of Arteries.*

THE vse of the great Artery and of his branches may bee considered two waues; either as they are Canales or Pipes, or as they moue and beate perpetually. As they are Canales or Pipes they haue three vses or ends. First to contayne spirituous and vitall bloud, and to distribute it vnto the whole body, partly for the perfect nourishment of the particular parts, for the parts, sayth *Galen* in the tenth chapter of his sixt Booke *de vsu partium*, which are neare vnto the Arteries doe draw out of the vaporous bloud though it be but little; partly for the nourishment and generation of the animall spirits. A double consideration of their vse. 3. vses as Canales.

The second vse is to leade vnto the parts vital spirits, to cherish and sustaine those vitall spirits which are seated in the parts. Thirdly, with the same spirit to transmit heate and the vitall faculty perpetually into the whole body, to cherish the in-bred heat of the particular parts, to moderate and gouerne their vitall functions and to defend their life.

As the Arteries doe beate, so haue they also a treble vse. The first is to preserue the in-bred heat of all the members which they do by ventilation or wafting ayre vnto them. For if it were not breathed it would by degrees languish and be extinguished. Their second vse is by their motion to make a kinde of commotion in the bloud (for the arteries accompany the veines) which if it were at rest would putrifie like standing waters, for bloud sayeth *Hippocrates* is water. The third vse is to solliciate and to compell the bloud to fall out of the veines into the substance of the parts for more speedy nourishment. 3. vses in respect of their motion.

This motion of the Arteries is called *pulsus* or pulsation (of the worde *Hippocrates* as *Galen* witnesseth was the first authour) which is absolued by dilatation and contraction: qualities not bred with the artery or seated in their substance, but flowing into them from the heart, which may be demonstrated if you intercept a part of an arterie with a tie, for the part that is vnder the tye will haue no motion, but as soone as the tye is taken away the motion will returne. Pulsation.

Erasistratus conceiued that the Arteries mooued quite contrary vnto the motion of the heart: but wee agree rather with *Herophilus*, *Aristotle* and *Galen*, who thinke they are dilated and constringed in the *Diastole* and *Systole* of the heart: onely we must remember, that the motion of the heart is swifter and more vehement then that of the arteries, which you may thus make experience off. Lay your right hand vpon your heart, and with your left hand touch the wrest of the right hand, and then you shall perceiue whether the motion of both bee the same or contrary, but the more certaine knowledge of this poynt is taken from the dissection of liuing creatures.

In the contraction of the Arteries they strongly driue vital spirits into the whole bo-

dy

dy and expel by expreſsion ſooty and ſmokie excrements ariſing from the humors which otherwiſe would ſuffocate the head. When they are dilated they ſnatch from the heart ſpirits as a new matter which in their contraction they communicate to the particular parts to be a vehikle of the heat, and do aſſume out of the neighbour veynes natural blood for their proper nouriſhment by the inoculations which are betwixt them, and the veines; and that is the reaſon eſpecially why the veines & the arteries do walke together throughout the whole body vnleſſe ſome great obſtacle be in the way. But the arteries lye vnder the veynes vnleſſe it be at the holy-bone, not ſo much for defence as becauſe by their motion they might conſtraine the veynes to powre out their blood, as alſo to make a conſpiration or conſent betwixt the veſſels, and a communion of their matters that the arteries might affoord vnto the veynes ſpirit and life, and the veynes vnto the Arteries naturall blood.

Why they lye vnder the veines.

Againe, by this vicinity of the veſſels the membranes which couer the veynes & tye them vnto the parts by which they paſſe, are alſo of great vſe vnto the Arteries.

It is alſo thought that theſe Arteries by the pores of the skin do draw Aier whereby the heate which is within is breathed, which breathing is called Tranſperation. But concerning the motions of the Arteries and by what faculty they are mooued, whether they moue as the heart mooueth, or contrary vnto it, wee haue intreated in the ſecond, third, fourth, and fift Queſtions of the Controuerſies of the ſixt booke, to which place we referre the Reader.

CHAP. XVIII. *Of the aſcending Trunke of the great Artery.*

The great Artery.

THE great artery at the left ventricle of the heart from whence it ariſeth is exceeding large, whence *Hippocrates*, *Plato*, *Ariſtotle*, and *Galen* haue al agreed that the heart is the fountaine and originall of Arteries, [Tab. 16, fig. 1^A] and before it fall out of the *Pericardium*, or purſe of the heart aboue the values, [Tab. 16, fig. 3, char. 1, 2, 3,] it affoordeth ſometimes one ſometimes two coronary arteries, [Tab. 16, fig. 1, 2, ^B] which like a Crowne do compaſſe the Baſis of the heart, and through the length thereof together with the veyne diſmiſſeth branches which are more and larger in the left ſide, and thoſe make the ſubſtance of the heart viuide or liuely. Preſently after, a little vnder the trunke of the Arteriall veyne, it ariſeth vpward & pierceth through the *Pericardium*, & is diuided into two vnequal parts, one of which aſcendeth vpward [Tab. 16, fig. 1, ^C] vnto the head which is the leſſer, the other and the greater by much runneth downward [Tab. 16, fig. 1, ^D] becauſe the parts of the creature which are vnder the hart are more a great many & greater then thoſe that are vnder it. This trunk is proportionably anſwerable to the ſtocke or body of the tree, and inclineth vnto the fift rackebone of the cheſt, and declining a little to the left hand to giue away vnto the hollow veine, it deſcendeth vpon the rack-bones vndiuided, which part *Ariſtotle* properly called *Aorta*, becauſe euen in dead bodies the nerrtous part thereof was conſpicuous, haply becauſe it is like to a Macedonian ſheath which is called ἀορτὴ. *Praxagoras* vſed to call it *Craſſa* or the thicke Artery. From this trunke, branches are diſperſed which accompany the branches of the gate and hollow veynes into the whole body.

The coronary Arteries.

The greater Trunke.

From the greater trunke therefore [Tab. 16, fig. 1, ^D] which in the cheſt is largeſt and thickeſt, do iſſue theſe branches following.

Intercoſtales Inferiores.

The lower intercoſtall Arteries [Tab. 16, fig. 1 H H H] which proceeding in order from his hinder ſide, are ſent on eyther hand to the diſtances of the eight lower ribs, as far as to their griſtles: and theſe againe do diſtribute ſurcles to the muſcles which grow vnto the backe and cheſt, and to the ſpinall marrow through the holes which are made in the rack-bones for the out-lets of the nerues, after the ſame manner that the veyne *Azygos* diſtributeth his branches: for it is very rare to find the veyne *Azygos* accompanied with an artery iſſuing from the *Aorta*, and then it may well bee called *Intercoſtalis maior*, or the great intercoſtall artery.

Phrenica.

Secondly iſſueth the artery called *Phrenica* on eyther ſide one, [Tab. 16, fig. 1, ^{**}] which is diſſeminated through the midriffe, and from theſe are ſmall branches, ſprinkled alſo to the *Pericardium* where it groweth to the midriffe. Sometime this *Phrenica* ariſeth from the trunke vnder the midriffe. The reſt of the trunke that remaineth paſſeth through the fiſſure of the midriffe [Tab. 15, fig. 1, *] cleauing to the bodies of the rack-bones and from it are many propagations diſtributed throughout the lower belly, of which we ſhal ſpeak in the next chap. and in in the 16.

From

From the leſſer and aſcending trunke [tab.16.fig.1 a] which amongſt the ſeparating membranes lieth vnder the hollow veine and reſteth vpon the rough artery are branches communicated to all the parts aboue the heart.

Firſt of all it ſendeth on either ſide a notable branch which vnder the coller bone attaineth vnto the firſt rib of his owne ſide, and therefore it is called the *Subclauian* artery. Afterward the whole trunke departeth into the two ſleepy arteries.

The right *ſubclauian* artery [tab.16.fig.1 b whoſe original is at a] iſſueth out of the *Aorta* where it is diuided into the ſleepy arteries: and this is the higher and larger branch, and runneth more ouerthwart then the left which ariſeth much lower where the *Aorta* is retorted downward and attaineth more obliquely vnto the arme. *The right ſubclauian artery.*

From either *ſubclauian* before it fal out of the cauity of the Cheſt (for when it is out of the Cheſt it is no more called *ſubclauia* but *Axillaris*) [tab.16.fig.1 rr] as ſoone as it toucheth the firſt rib and not before, are propagations deriued from the lower part; firſt.

Table 16. Is the ſame with Table 13. in folio 382.

The vpper intercoſtall [Tab.16.fig.1, LI] which being faſtned to the roots of the ribs communicateth particular branches to three or foure diſtances of the vpper ribs on his owne ſide; (But not alwayes after the ſame manner) from which ſurcles are diſtributed to the marrowe of the backe and to the Neighbour-muſcles. From the vpper part doe yſſue. *Intercoſtalis ſuperior.*

Firſt, the *Mammaria* or the Artery of the paps [Tab.16 fig.1 ll] which being reflected vnder the breſt-bone deſcendeth accompanied with a Veine vnto the pappes and the muſcles [Tab.16.fig.1 ccc] which occupy the diſtances of the griſtles of the true ribbes. It ſprinkleth alſo ſurcles into the Glandules and the parting or diuiding membranes vnto which it adhereth, and at the ſide of the griſtle called the breſt-blade yſſueth out of the Cheſt and runneth vnder the right muſcles of the *Abdomen* diſperſing his fauors into the ſides. At the Nauell it is diuided into many ſurcles, [Tab.16.fig.1 dd] and is ioyned with the Epigaſtricke Artery which plyeth vpward. [Tab.16.fig.1. e e] *Mammaria.*

The next artery which ariſeth from the vpper part of the Subclauian trunke is called *Ceruicalis* or the artery of the necke. [Tab.16.fig.1 mm] It iſſueth more backward towarde the bodies of the racke bones, ſometimes from the ſleepy artery, and aſcending vpwarde when it hath attained vnto the ſeuenth rackbone of the neck, it paſſeth through the holes in the tranſuerſe proceſſes of the ſaide rackbones, for which cauſe alſo Nature made thē perforated; and diſtributeth his ſurcles to the muſcles, the marrow of the necke, and to the Rack-bones. Theſe ſurcles go in where the nerues get out. There this artery perforating the membrane of the marrow betwixt the firſt racke and the Nowle-bone [tab.16.f. 1 nn] entreth on both ſides into the ſcull, ioyneth with his oppoſite & runneth along the baſis of the Braine. *Ceruicalis.*

The third is called *Muſcula* [tab.16. fig.1. OO] It ſendeth branches vnto the Muſcles which lye vpon the necke as farre as the nowle: ſometimes alſo to the Muſcles of the Arme. *Muſcula.*

After this trunke hath gotten out of the cauity of the Cheſt, wee ſaide before that it getteth a new name and is called *Axillaris*. From the axillary Artery therefore [tab.16.fig 1 rr] before it attaine vnto the arme there yſſue three Arteries.

The firſt is called *Thoracica ſuperior* [tab.16.figu. 1, qq] which runneth on eyther ſide with aboundant ſurcles vnto the Muſcles which lye vpon the breſt, and next vnto theſe are thoſe ſmall ſhootes which are allowed to the little glandules vnder the Arme-pits. *Axilaris arteria Thoracica ſuperior.*

The ſecond is called *Thoracica inferior* [tab.16.f.1 ss] which runneth downward all along the ſide of the cheſt, eſpecially into that muſcle which is called *Latiſsimus* or the Broade Muſcle. *Thoracica inferior.*

The third is called *Scapularis* [Tab.16.fig. 1 S] which is diſſeminated into the Muſcles repoſed in the hollowe ſide of the ſhoulder-blade. From the vpper part of the Axillarie branch ariſeth one artery called *Humeraria* [tab.16.fig.1 tt] which climbeth to the top of the ſhoulder, and is diſtributed to the Muſcles which occupy the arme and the gibbous ſide of the blade. That which remaineth of the axillary artery [tab.16.figu.1 vv] runneth away vnto the arme being accompanied with the axillary veine whoſe diuiſions we ſhall finde in the 19 chapter. *Scapularis.* *Humeraria.*

The remainder of the aſcending trunke [tab.16.fig.1 b] reſting it ſelfe vpon the rough artery toward the vpper part of the breſt-bone being yet in the cauity of the cheſt is ſupported

Carotides

ported with the *Thymus*, and diuided into two vnequall branches which they call *Carotides* [tab.16.fig.1 x y] or *Soporales* the sleepy Arteries. These tend directly vpward, so that the right as also the left run through the sides of the neck vnto the basis of the scull being tied to the tough Artery and the internall Iugular veines with a membrane, (for the Externall Iugulars are without arteries) and so reach vnto the heade where wee shall finde them in the 17 chapter.

CHAP. XV. *Of the descending trunke of the great Artery accompanying the Hollow Veine.*

7 braunches before the diuision.

THE Trunke of the great Artery [Tab. 17 h] at the eleuenth racke-bone of the Chest passing through the Midriffe [Tab.17.char.4] runneth through the lower belly leaning vpon the left side of the bodies of the racks, and lying vnder the left side [tab.17.L] of the hollow veine [Tab.17,x] declining somewhat to giue roome thereunto, and before it come to the last Racke saue one of the Loines, in some bodies at the Holy-bone [tab. 17, char.14] where it is diuided into two trunkes, it affoordeth seuen branches, whereof some do accompany the branches of the Gate-veine, as that called *Cœliaca* and the double Mesenterical branch which depart vnto the Stomacke, the Mesentery and the Guts, of which we shall speake particularly in the next chapter.

Others accompany the branches of the Hollow-veine couered with the *Peritonæum* or Rim of the belly, of which we shall intreat in this chapter. For Nature almost alwaies diuideth the Arteries where she diuideth the Veynes, partly that the membranes wherewith she coureth the Veines and fastneth them to the neighbour parts might bee of vse likewise vnto the Arteries, partly also that there might be a conspiration between the vessels and a communion of matters, for there are few Veines without arteries ioyned vnto them vnlesse it be those that run immediately vnder the skin. Now the order of the branches as they arise out of the trunke is on this manner.

Cœliaca. Mesenterica superior. Emulgens

The first is called *Cœliaca* [Tab.17, char.6]

The second *Mesenterica superior*. [Tab.17,char.10]

The third *Emulgens* or *Renalis* the artery of the Kidneyes [Tab.17, d e] one left and another Right, sometimes but rarely we finde three or foure or more. This is a notable branch and well nie the greatest of all that arise from out of the great artery. It issueth out of either side of the trunke where the first and second rack-bone of the Loins are coupled with a Ligament, and pacing obliquely at the cauity of the Kidneyes it is diuided as the Veines are, and so implanted thereinto and therein consumed, imitating for the most part the distribution of the Veines.

Their Vse.

Their vse is not so much to leade vitall blood as to purge away the whey from the vital blood of which there is aboundance in the great artery. Notwithstanding the fat Membrane of the Kidnies though they be neere at hand, doe not scarse at all partake of these arteries.

Spermatica.

The fourth is called *Spermatica*, the seede artery. [Tab.17,char.11] Both of them issue together (for their originals do touch) out of the forepart of the trunke, and descending the right rideth ouer the trunke of the hollow veine, is fastned vnto the spermaticall veine of his owne side (as the left is to the left) by the mediation of the *Peritonæum*. Afterwarde in men they passe the productions of the same *peritonæum* and are applyed with a winding passage to the Testicles, whereto as also to their coats they affoord furcles. The vse of which application is to leade vnto them venall and arteriall bloode and vitall spirits. But in women the one halfe goeth to the Testicles, the other vnto the bodye of the wombe. And from these *Columbus* thought the vmbilicall arteries had their original, but what reason he had for his conceite there I leaue him.

Mesenterica inferiour. Lumbaris

The fift is called *Mesenterica inferior*. [Tab.17, Char. 12]

Table xvij. Is the same with the eight of the third Booke in folio 115.

The sixt is called *Lumbaris* [Tab.17 the vpper mmmm] These are two arising out of the backside of the Trunke where it ioyneth to the rackbones and run crookedly through the holes of the rackes of the Loynes and are distributed vnto the spinall marrow, as also the Neighbor-muscles & to the *Peritonæum*. These also at the sides of the marrow together with the veines run vpward to the braine. *Columbus* maketh mention of no more braunches before the diuision of the great artery, but *Laurentius* whom *Bauhine* also followeth addeth a seuenth.

The

The ſeauenth therefore is called *Muſcula ſuperior* [Ta.17.the lower mm] which alſo is referred to the *Lumbares* but larger then the reſt and runneth out vnto the ſides of the *Abdomen*, and bleſſeth his muſcles with aboundant ſurcles. *muſcula ſuperior*

After theſe branches are diſtributed, the great artery at the beginning of the Holy-bone [Ta.17.char.14.]climeth ouer the hollow veine, not as challenging the ſuperiority, but becauſe being perpetually mooued it might haue beene offended if it had beaten againſt the bare bone.

At this place by reaſon of the parts through which it paſſeth it is called *Iliaca*, [Tab. 17.'] and as the hollow veine ſo is it deuided aboue the body of the fourth Racke of the Loynes into two trunkes after the manner of X inuerted or turned vpſide downe. Vnder this bifurcation yſſueth the artery called *Sacra* [Tab.17.°°] whoſe ſurcles runne through the holes of the holy bone vnto his marrow. Not far from the deuiſion each trunke [Tab 17.f] is deuided into an interior or ſlender branch [Tab.17.e] and an exterior or greater [Ta.17.5] which falleth vnto the Leg. From the interior branch yſſue two propagations, one vtter the other inner. The bifurcation of the trunke.

The vtter is called *Muſcula inferior* [Ta.17.ff] and runneth tranſuerſly [Ta.17.f] outward betwixt the holy-bone and the bone of the hip, and is diſtributed with many ſurcles into the muſcles which couer the haunch-bones and the hippe-ioynt. In like manner at the groyne from one of the trunkes ariſeth a notable branch which runneth vnto the skin and cheriſheth the *Cutany* parts which appertayne vnto the ſhare, to the hanches and to the *abdomen*. *Muſcula infer.*

The inner is called *Hypogaſtrica* [Ta.17.aa] which is the largeſt of all the reſt, and runneth directly downward to the lower part of the *Os ſacrum*, to the bladder and his necke, (ſome ſay alſo to the fundament, and may there be called the *Hemeroidall* arteries) and finally to the muſcles which couer the ſhare-bone, into all which parts his ſurcles are diſtributed. *Hypogaſtrica.*

In women this *Hypogaſtrica* is yet larger, and is diſtributed aboundantly into the bottom of the wombe. It ſprinkleth alſo the necke thereof and the bladder with ſmall ſurcles. It ſendeth foorth alſo a branch which vnder the bifurcated originall of the yarde runneth ſtrangely intangled to his two hollow bodies, ſo making a kinde of web or complication and then paſſeth vnto the nut. The remaynder of the *interior* branch [ta.17.e] creepeth downward, and admitteth vnto it the vmbilicall artery [ta.17.at] which paſſeth throughout the length of the great artery, & at the ſides of the bladder for more ſtrength is tyed with ſtrong membranes, by which vmbilicall artery the Infant in the wombe liueth and enioyeth Tranſpiration, but after the Infant is borne it turneth into a tye or ligament of which we haue ſpoken ſufficiently before. *Arteria vmbilicalis.*

Preſently after when it hath aſſumed a propagation which is ſent obliquely downward from the external branch [ta.17.5] where it is about to fall into the Leg, [ta.17.f] it paſſeth through the hole of the ſhare-bone, and is diſperſed into the muſcles which occupy that hole, and into thoſe that neighbour about it.

The *Exterior* branch of the byfurcation ſendeth out two branches, one before it hath paſſed the *Peritoneum*, another after.

The firſt is called *Epigaſtrica*, [Tab.17.char.22.] and reflected vpward, climeth ouer the right muſcle, and his eſpeciall branches about the Region of the Nauell are ioyned with the mammary; the reſt of his ſurcles hee diſperſeth tranſuerſly into the lower ſide of the *abdomen*. *Epigaſtrica.*

The ſecond is called *Pudenda* [Ta.17.char.15.] a little branch not deuided into ſo many ſurcles as is the veine. It runneth tranſuerſly and inward along the commiſſure or ioyning together of the ſhare-bones vnto the Priuities, and is conſumed in the skinne of the yard. Sometime alſo ſmall arteries are ſent vnto the glandules of the groynes againe often from one ſide a reaſonable braunch is produced vnto the groyne, which cheriſheth not onely the skinne about the ſhare, but alſo thoſe partes which pertaine or reach vnto the haunches or to the *abdomen*. The remaynder of the artery [Ta.17.char.18.] runneth into the Leg and maketh the *Crurall* arteries, of which we ſhall ſpeake in the 20. Chapter: and thus much of the braunches of the great Artery which accompany the hollow veine in the lower belly. Now we come vnto thoſe that accompany the Gate veine. *Pudenda.* *Crurales.*

CHAP.

CHAP. XVI. *Of the Arteries accompaning the branches of the Gate-veyne through the lower Belly.*

THE arteries which accompany the branches of the Gate-veyne are three. The first is called *Cœliaca* [Tab.18,fig.1,[m] Tab.17,char.6,] the second *Mesenterica superior*, [Tab.17,char.10,] The third *mesenterica inferior*, [Tab.17, char.12.] The *Cœliaca* [Tab.18,fig.1,[m] Tab.17,char.6.] is so callled because it sendeth many branches vnto the stomacke, and therefore wee may call it the stomacke artery. It is a notable vessell and because like the gate-veyne it offers his branches to the stomacke, the kell, the *Duodenum*, the beginning of the *Ieiunum*, a part of the collicke gut, to the Liuer, the bladder of gall, the *Pancreas* and the spleene, wee will fit his names vnto the names of the gate-veyne.

Cœliaca.

Is ariseth from the forepart of the body of the great artery at the spine of the backe. And the vpper part thereof is sustained in his course by the lower membrane of the *Omentum* or kell. Afterward it is diuided into two branches, a right [Tab.18, fig.1,[n]] which is the lesser, and a left [Tab.18,fig.1,[o]] which is somewhat greater. Both of them spring as it were out of one roote, and vnder the back-side of the stomacke are fastened to the gate-veyne in the *Pancreas*.

The diuision thereof.

The right [Tab.18,figure 1,[n]] ascendeth vpward into the hollow part of the Liuer, hauing some part of his way sprinkled branches, some from his vpper part some from his lower. From his vpper part two.

Gastrica dextra.

The first is called *Gastrica dextra*, the right stomacke artery. [Tab.18,fig1,[p]] It issueth out of the middle of the passage and distributeth his surcles into the backe-side of the right orifice of the stomacke.

Cystice gemellæ.

The second are two small twin-branches called *Cystice gemellæ*, [Tab.17,char.8,Tab. 18,fig.1,[r] fig.2,[x]] because they go vnto the bladder of gall. From the lower branch issue three branches.

Epiploïs dextra.

The first is called *Epiploïs dextra* the right Kell artery, [Tab.18,fig.1,[o] fig.2,[b]] and is offered to the right side of the lower kell, and to the collicke gut which is fastened thereto.

Intestinalis.

The second is called *Intestinalis*, the gut artery, [Tab.18,fig.1,[s] fig.2,[d]] and is sent vnto the *Duodenum* and the beginning of the *Ieiunum*.

Gastro epiploïs dextra.

The third is called *Gastro-Epiploïs dextra*, the right stomacke and kell-artery. [Tab.18, fig.1,[t]] It is larger then the former, and is retorted or bent backward to the right side of the bottome of the stomack, and leaning vppon the vpper membrane of the Kell, sprinkleth very plentifull surcles into the foreside and hindside of the bottome of the stomacke, as farre as vnto the middle thereof. That which remaineth of the right branch determineth into the hollow part of the Liuer, [Tab.17,char.7, Tab.18,fig.1,[u] fig.2,[f]] yet not deepe, so may you see it is all spirit.

Arteria splenica

The left branch [Tab.18,fig.1,[p]] which is also called *Arteria splenica*, the Artery of the spleene passeth with an oblique and crooked course through the *Pancreas* [Tab.18, fig.1,[q]] vnto the Spleen [Tab.18,fig.2,[m]] It is larger then the right branch that it might not easily be obstructed, for it doth not onely suggest into the Spleene plenty of vitall spirits, but also voideth out and purgeth into the same the thicker and more fœculent matter of the spirituous blood contained in the great Artery. It is fastened to the spleenish veyne and is distributed like vnto it, for from it before the diuision there issue from the vpper part two Arteries, and as many from the lower.

His diuision.

Gastrica maior.

The first that issueth from the vpper part is called *Gastrica maior*, the greater stomacke Artery [Tab.18,fig.1,[y]] which offereth to the stomacke a propagation in the backe and vpper part, whereof a surcle [Tab.18,fig.1,[f]] runneth vnto the middest of the stomack.

Coronaria stomachica.

Another also called *Coronaria stomachica*, the Crowne artery of the stomacke, [Tab.18, fig.1,ch.2,fig.2,[x]] which reacheth to the vpper orifice compassing it about like a crowne, and it also sendeth small surcles to the body of the stomacke and to the gullet.

Gastrica sinistra

The second is called *Gastrica sinistra*, the left stomacke artery. [Tab. 18,fig.1,[e]] It is a propagation of the former *Gastrica maior* running on the right hand into the vpper parts of the stomacke, and distributing surcles on both hands which attayne vnto the *Pylorus* or lower mouth of the stomacke.

Epiploïs postica.

From the lower part of the left branch issue likewise two arteries. The first is called *Epiploïs postica*, [tab. 18,fig.1,[β] fig.2,[c]] the hinder kell-artery, which presently is diuided into

into two ſurcles ſeparated farre one from another, and thoſe into others which are propagated into the lower membrane of the kell and the collick-gut which is tyed thereto.

Table 18 is the ſame with Table 4. Lib. 3. folio 102.

The ſecond is called *Epiploïs ſiniſtra*, the left kell-artery. [Tab. 18, fig. 1,] It is alſo ſent to the lower membrane of the kell and runneth out into his left ſide. That which remaineth of this branch [Tab. 18, fig. 1, u] attaineth to the ſpleene, and is diuided into an vpper and a lower branch, and theſe againe are diuided into others vntill many branches doe touch the hollow part of the ſpleene, [Tab. 18, fig. 1, ſ] and are diſperſed through his ſubſtance. *Epiploïs ſiniſtra*

Table 19 is the ſame with Table 7. Lib. 7. folio 448.

Out of the lower part of this remainder iſſueth that artery which is called *Gaſtro-epiploïs ſiniſtra*, [Tab. 18, fig. 1, t] which is ſupported by the vpper membrane of the *Omentum*, writhen toward the right hand that it might creepe vp the left part of the bottom of the ſtomacke, and ſendeth crooked and bent branches to the fore ſide and back-ſide thereof, and to the vpper membrane of the kell. *Gaſtro-epiploïs ſiniſtra.*

Out of the vpper part of the remainder iſſueth that which is called *Vas breue arterioſum, The ſhort arteriall veſſell*, which is inſerted into the vpper part of the left ſide of the bottome of the ſtomacke. *Vas breue arterioſum.*

And this is the diuiſion of the *Cœliacall* Artery in the lower belly which is the firſt of the three that accompany the branches of the Gate-veine. The ſecond and third are the two Meſenterick Arteries both which yſſue from the foreſide of the trunke, the vpper below the *Cœliacal*, the lower below the Spermaticall.

The vpper Meſentericall artery [Tab. 17, char. 10, Tab. 18, fig. 1. & fig. 2, r] is propagated into the vpper part of the Meſentery, yea almoſt into all of it, and ſprinkleth abundant ſurcles into the *Ieiunum*, the *Ilion*, and the Collick guts at the right kidney. *Meſenterica ſuperior.*

The lower meſentericall artery, [Tab. 17, char. 12, Tab. 18, fig. 2, q] runneth vnder the lower ſide of the meſentery and is eſpecially diſtributed into the left ſide of the collick and into the right gut, and deſcending together with the veynes vnto the fundament, maketh the Hemorrhoidall Arteries. [Tab. 18, fig. *] *Inferior.* *Hemorrhoidales*

The vſe of theſe meſentericall branches is not ſo much to conuay heate vnto the parts, as by their motion and vitall ſpirit to preſerue the meſentery and the guts from corruption and putrifaction. The vſe of the meſenterical artery.

Some are of opinion that theſe branches do ſucke out of the guts the pureſt part of the chylus for the generation of arteriall blood and conuay it to the left ventricle of the heart: but the values which are ſet at the beginning of the great artery, and ſhutte vp the paſſage from the artery into the heart onely, & not out of it againe, do contradict ſtrongly that conceite. *Varolius* his conceite Refuted.

Hauing thus brought the great artery through the middle and lower regions of the body, we wil now returne vnto it again, where we left it in the end of the 14 chapter diuided into two Soporary Arteries and climing vnto the Head.

CHAP. XVII. *Of the Arteries of the Braine.*

THE artery called *Carotis* or the ſleepy artery, and by *Archangelus Arteria Iugularis* becauſe it is accompanied on the inſide with the internall Iugular veyne, aſcendeth vnto the chops on eyther hand by the ſides of the rough artery, and there is diuided into two branches. One externall, of which we ſhal ſpeake in the chapter following. Another internall, which is alſo the larger conuayed to the Chops, which hauing affoorded certaine ſurcles to the tongue & the Larinx is diuided at the baſis of the braine [Tab. 19, fig. 13, x] into two vnequall branches. The ſleepy artery. His diuiſion.

The firſt artery of the brain according to *Bauhine*, according to *Veſalius* the 3, [ta. 19, fi. 13. fi. 15, cc] is little leſſer then the Trunk it ſelfe, & runneth vp whole & ful til it come vnto a proper hole bored for it in the temple-bone, & through it attaineth into the cauity of the Scull at the ſaddle of the wedge-bone, and being yet vnder the *Dura mater*, firſt of al it affoordeth a branch on each hand into the ſide of the ſame Meninx. [Tab. 19, fig. 15, b] Afterward in brute beaſts it parteth with an infinite number of ſurcles, and maketh that texture which is called *Rete mirabile*, the wonderfull Net; of which *Galen* wrote ſo curiouſly that *Veſalius* followeth him to a haire, and that figure is the 14 of this 19 Table, but the 16 fig. of the ſame table exhibiteth the forme thereof, as it appeareth in brute beaſts eſpecially in Oxen, Calues, and Sheepe. The firſt artery of the Braine. *Rete mirabile.*

In men though there be indeed ſuch a knot or texture, yet it is not ſo notable, and but a very

very ſhadow in reſpect of that in bruite beaſts, and yet notwithſtanding the Artery is not conſumed into theſe propagations but remaineth alwayes ſound. [Table. 19. fig, 16, [a c]] Preſently after it perforateth the *dura meninx* and runneth ſometimes ſingle, ſometimes double, [tab. 19. fig. 15 [r]] yet ſo that it preſently vniteth again, and when it hath tranſmitted the leſſer branch [k] through the ſecond hole of the VVedge-bone, it creepeth out of the ſcull vnto the eye and the temporall Muſcle [tab. 19. figu. 11 [n]] together with the Opticke nerue to giue it and his Muſcles life, & ſendeth the greater branch vpwarde, which preſently at the ſide of the Flegmaticke Glandule is diuided into two branches. The inner wher of is vnited with the inner arterie of the oppoſite ſide, and ſo being vnited they are conſumed into many ſmal arteries which at the original of the optick nerues are diſſeminated through the *pia Mater* and the ſubſtance of the Braine. [Tab. 19. fig. 13 [c]] The other being reflected [tab. 19. fig. 13. at the vppermoſt [a] fig. 15 [o]] and entangled in the *Pia Mater*, runneth into the forward ventricle diuided into many ſmall braunches, ſome of which are vnited with thoſe ſmall arteries which attained hither from the *Cernicalis* or artery of the necke through the baſis of the Head vnder the Braine. Some others run diſioyned through the *pia mater* or thin membrane and through the ſubſtance of the Braine it ſelfe, which with other ſurcles make that complication of veſſels which they call *Plexus Choroides*, ſo that this complication is compounded of foure arteries.

Plexus Choroides.

The ſecond Artery of the Braine [ta. 19. fig. 13 [q]] is a branch of the former which runneth obliquely, and when it hath attained into the ſcull through the ſecond hole of the Temple-bone, it is diuided into two branches; whereof one runneth outward and the other inward. The vtter which *Veſalius* calleth the ſecond ſmall branch of the third artery [tab. 19. fig. 13 [ſ]] endeth through the eight hole of the Wedge-bone into the cauity of the Noſethrilles [Tab. 19. figure. 15 [x]] where the Pulſe is felt, and offers a little ſurcle to the end of the Noſe [Tab. 19. fig. 13, [t]] but the interiour branch is diuided into two at the firſt Hand [tab. 19. fig. 13 [uu]] which *Veſalius* calleth two great branches of the third artery. Afterward it ſendeth out of his vtter part another ſmall braunch, [Tab. 19. fig. 13 [r]] which *Veſalius* calleth the firſt ſmall branch of the third Artery, this branch togither with the ſecond Veine, [x] and after the ſame manner and for the ſame vſe is diſtributed into the *dura meninx* or thicke Membrane.

The 2 Artery.

The pulſe of the Noſe.

The third Artery of the Braine which according to *Veſalius* and *Platerus* is the ſecond, [Tab. 19. fig. 13, I] is leſſe then the firſt and runneth together with the branch of the internall Iugular veine [tab. 19. fig. 13, C] vnto the backeſide of the Scull, and hauing affoorded a ſurcle vnto the Muſcles which occupy the inſide of the necke [*] it entreth in at the firſt hole of the Nowl-bone, and ſo paſſeth into the *ſinus* of the *dura Meninx*.

The 3. arterie of the Braine.

The fourth Artery (which according to *Veſalius*, *Falopius* and *Platerus* is the firſt) is a propagation of that axillary artery being yet within the Cheſt which is called *Cernicalis*. This ariſing vpward through the holes of the tranſuerſe proceſſes of the neck, after it hath giuen ſome ſurcles to the muſcles thereabout, betwixt the head and the firſt Racke of the necke it perforateth the thicke membrane which inueſteth the ſpinall marrowe in the ſide thereof: to which after it hath giuen ſome propagations it entreth into the cauity of the Scull through the great hole. Afterward vnder the marrow it is ioyned with his companion of the oppoſite ſide, which being ſo vnited do paſſe along vnder the middle of the baſis of the Braine till it come vnto the ſaddle of the Wedgebone wherein the Phlegmaticke Glandule is contained. There againe it is diuided into two braunches. The right runneth to the right ſide of the ſaddle, the left creepeth on his owne ſide as farre as to the ſecond paire of ſinewes, where on both hands it is diuided into infinite ſurcles and diſſeminated betwixt the firſt and ſecond paire of ſinews, and complicated or intangled with the *Pia Mater* which afterward do make the *Plexus Choroides*. And thus much of the diſtribution of the arteries within the braine.

The fourth.

Moreouer, we muſt imagine that from theſe ſleepy arteries an innumerable number of ſurcles or propagations are ſprinkled heere and there throughout the whole ſubſtance of the Braine.

The vſe of the arteries of the Braine.

The Vſe of the arteries of the Braine is to bee conſidred either as they are Canales or pipes running through the Braine, or as they are perpetually mooued.

In the firſt conſideration they were made to conuey vitall Bloode from the Heart vnto the Braine, as alſo vitall ſpirits to ſuſtaine the vitall ſpirits that are bred and ſeated in the ſubſtance thereof; neyther do they carrie vitall ſpirits onely, but alſo the vitall facul-

tie

ty furniſhed with all his indowments.

As they beat continually their vſe is perpetually to ventilate the ingenite heate of the Braine, which otherwiſe would quickly languiſh and be extinguiſhed. Againe, this pulſation moueth and worketh the bloud in the veines, which if it ſtood ſtil and at reſt would like ſtanding water ſooner putrifie and corrupt. Finally, to ſollicite the Alimentary bloud which is thicker, to yſſue out of the veines through ſmall pores and vents or breathing paſſages into the ſubſtance of the braine (which alſo doeth ſomewhat drawe it) for his nouriſhment and refection.

Now we proceede vnto the exterior branch of the Sleepy Artery.

CHAP. XVIII. *Of the Arteries of the Face, the Eyes, the Noſe, the Teeth, and the Larynx.*

THE *Carotides* or ſleepy Arteries [Tab. 16.[x y]] being on both ſides one, doe accompany the Iugular veines by the ſides of the neck, and cleauing to the Rough artery aſcend vnto the head, and when they come vnto the Chops they are deuided [Tab. 16.[ff]] into an vtter branch [[g]] and an inner, [[h]] the diſtribution of the inner we had in the former Chapter. The diuiſion of the ſleepy artery.

The vtter which is ſmaller then the inner, and conſiſteth without the Choppes, lendeth ſurcles to the Cheeks [[l]] and to the muſcles of the Face, afterward when it commeth vnto the roote of the Eare [[m]] it is deuided into twaine, one of which runneth to the backſide of the Eare, [[o]] from which two arteries vnder the Eare doe paſſe into the neather Iaw, & throughout the length thereof are diſperſed vnto the roots of all the lower teeth, another part of it breaking out through a hole at the Chinne runneth along the Lip; another yet [[n]] creepeth vp the Temples and the forehead, and is conſumed into the muſcles of the Face. Of the Arteries of the Eyes we haue ſpoken before in the former Chapter, as alſo of the Noſe; of the Teeth a little before, whence it is that wee often finde pulſing or beating paines in them, ſuch as wee feele in inflamations of fleſhy partes, and this was *Galens* obſeruation in the 8. chapter of his fift Book *de compoſitione medicamentorum ſecundam loca*, who found in himſelfe not onely the paine of his Teeth, but alſo their beating or pulſation, wherefore he affirmeth confidently that there is one kinde of paine in the gums and another in the ſubſtance of the Tooth, and without the inflamation of the Gummes ſometime in the proper body of the Tooth, ſometimes in the Nerue paines doe perplex vs. And truely if there were no Artery at the roote of the Teeth, how could it bee that when a Tooth is perforated, ſo much cleare and perfect bloud ſhould yſſue out from it? Which as *Euſtachius* ſayth he obſerued in a man who had ſo great a fluxe of bloud from his tooth that almoſt powred out his life therewith. *Galen.* That there are arteries in the teeth. *Euſtachius his obſeruation.*

Finally, which wee alſo partly remembred before, from the greater and inner bough of the ſleepy artery which runneth vnder the Choppes, ſome ſurcles are communicated to the Throttle and Tongue to conuay vnto them life and heat: and thus much of the diuarication of the *Soporary* or ſleepy arteries both without the Scull and within: it remayneth that we ſhould entreat of the *Axillary* and *Crurall* arteries, as they are diſtributed into the ioynts, but we will begin with the Axillarie.

CHAP. XIX. *Of the arteries of the Hand in the large acception.*

THE great Artery after it is out of the Cheſt diſtributeth foure branches from each ſide of the Axillary; the firſt from the backeſide to the Muſcles ſituated vpon the ſhoulder blade; [table 20. fig. 2. I] another from abone from the ioynte of the Arme with the blade, which the *Humerarie* veine accompanyeth for a time, [[k]] the third to the Muſcles that lye vpon the forepart of the Cheſt, [[l]] the fourth runneth downeward along the ſides of the Cheſt [[m]] and communicateth ſmal branches to the glandules vnder the arm-pits betwixt the third branch and the fourth, of theſe we haue ſpoken before: the remaynder is conuayed vnto the hand [from [n]]. 4 branches from the axillarie.

For this branch [[n]] deſcending through the inſide of the Arme together with the *Baſilica* veine [tab. 20. fig. 1.[m]] betwixt the muſcle called *Biceps* or the two headed muſcle, diſtributeth ſmall ſurcles on either ſide to the muſcles which take vp the inſide of the arme. [vnder [n]] Afterward being accompanyed with the *Deepe-veine* [tab. 20. fig. 1.[q]] or the inner branch of the *Baſilica* (whereto it is faſtned in his whole courſe) as alſo with the fourth

Table 20. Fig. 2. ſheweth the branches of the great Artery running thorough the whole Hand.

TABVLA XX.

G. The Mammary artery faſtned on the outſide into the breaſt-bone.
H, The Artery of the neck called *Cervicalis* going to the backeward muſcles of the neck.
I, *Scapularis* going to the muſcles of the ſhoulder-blade.
K, The Artery climbing vnto the top of the ſhoulder.
L, *Thoracica ſuperior* going to the muſcles that ly vpon the breſt
M, *Thoracica inferior*, creeping along the ſides of the Cheſt.
N, The axillary arterie attayning vnto the arme, and beſtowing ſmall branches to the muſcles.
O. It attaineth to the outſide of the cubit.
PP. Vnto the ioynt of the cubit.
† The by-partition of the Arterie vnder the bought of the Cubite.
Q An vpper branch of the artery carried along the Wand.
R. A ſurcle going vnto the vtter ſides of the Hande, where wee vſe to feele the pulſe.
S. The lower branch of the Artery running along the *Vlna*.
* A ſmall branch to the muſcles about the little finger.
T. The diſtribution of the vpper and inner braunches into the hand and into the fingers.

Nerue of the arme it runneth through the backſide into the outſide of the cubit vnder the heads of the muſcles thence ariſing, and ſhooteth foorth ſmall branches aboue and below [O] and neere the bent of the elbow it affoordeth on either ſide two branches tothe ioynt [PP] where the pulſe may be oftentimes euidently felt.

Galen. The Anaſtomoſis of the veſſels.

VVe ſaide that the Artery runneth with the veine, *For it is certaine* (ſaith *Galen* in the 10 and 17 chapters of his ſixt Booke *de vſu partium*) *that in the whole body there is a mutual Anaſtomoſis or inoculation betweene them*, that is, their mouths open one into another, *& ſo a Conſpiration and Communion of their matters*. For the arteries doe impart vnto the bloode ſpirites and vitall heate, and for retribution the arteries draw out of the veynes blood which is the nouriſhment not onely of their ſpirits but of the arteries themſelues; and theſe coniunctions of the veſſels made by their orifices or mouthes are found eſpecially in the armes and the legges, and therefore it hapneth ſometimes that one only vein being wounded, not onely all the naturall blood of the bodye but togerher with it the vital alſo iſſueth, & ſo the wounded man periſheth. And this *Galē* alſo intimateth, for going about to demonſtrate the vnions of the veſſels, he ſaith, that if the greater veins be wounded, if the blood be ſuffered to flow foorth, the Arteries alſo will bee euacuated by conſeqution: and this apeareth true by experience. For if you open a man that dieth of bleeding, you ſhall finde not onely the veines but the arteries alſo empty. But I return from whence I haue digreſſed.

Galen.

The Axillary Arteries deſcent.

The Axillarie Artery vnder the bent of the Cubit when it hath run a little way thorough the inſide of the Cubit, deſcendeth into two bending muſcles of the fingers, and is diuided into two notable branches; *Columbus* addeth oftentimes into three. The one is the vpper and paſſeth along the *Radius* or wand [Q] till it come in a ſtraight line vnto the wreſt, at which place the Phyſitians commonly feele the pulſe, making eſtimation of the diſpoſition of the hart from the Dilatation, Contraction, and intermediat Reſt of the artery,

tery. Yet ſaith *Columbus* this is not alwayes ſeated in the inſide of the wreſt, but runneth ſometimes outward, ſo that if a Phyſition be ignorant of Anatomy, and ſearch for the ſicke mans pulſe only in the vſuall place which is in the inſide of the wreſt a little aboue the roote of the thumbe, not finding it, hee will determine that the Patient is neere his death, when haply the artery beateth well on the vpper ſide againſt that place. The pulſe in the wreſt. Note this.

Before the artery of the pulſe get vnto the fingers it ſendeth a ſhoote toward the outſide of the hand [Tab.20,ᵃ] betwixt the firſt bone of the thumbe and that of the After-wreſt whereby the fore-finger is ſupported, & diſtributeth it into the muſcles of that place. Afterward it goeth vnder the Annular or tranſuerſe ligament, & the tendon of the muſcle of the Palme (as alſo do the veyne and the nerue faſtened therto) and is diuided into three branches. The firſt of theſe offers two ſurcles to the inſide of the thumb, the ſecond to the inſide of the fore finger, the third is vndiuided and attaineth to the middle finger, [Ta.20, betweene ᵃ and ᵗ.] Three branches to the fingers.

The other and inferior branch (of which *Columbus* maketh no mention) [Tab.20,ᵗ] runneth directly along the *Vlna* or *Ell*, and attaineth likewiſe to the wreſt, at which place alſo we may feele the pulſe to beate, eſpecially if the party be leane, or haue a great pulſe, and this is the reaſon why we rather touch the other artery then this, for the other is leſſe couered by the tendons and offereth it ſelfe more manifeſtly that we may giue the better iudgement by it. The lower branch of the *Axilary*.

This branch alſo runneth vnder the fore-ſaide tranſuerſe ligament into the palme of the hand, and before it reach vnto the fingers affoordeth a ſmall branch [Tab.20,*] to the muſcles that are ſeated neere the little finger. The remainder accompanied with a veyne and an artery is communicated to the fingers; the middle finger hath one ſurcle, the ring-finger and the little finger each of them two. The outſide of the hand as it wanteth muſcles ſo it wanteth arteries alſo, vnleſſe it be that branch which is marked with R. His diuiſion

And thus much of the Arteries of the Hand.

CHAP.XX. *Of the Arteries of the Foote in the large Acception.*

WEe ſaide before that the great Artery about the lower ſpondels or rack-bones of the Loynes, or aboue the beginning of the *Os ſacrum* or holy-bone is diuided into two notable Iliacke branches. [Tab.21,ᵣᵣ] Each of theſe is againe ſubdiuided on eyther ſide into two others, one exterior the other interior. [Tab.21,ξ ο.] The diuiſion of the *Iliack* Arteries.

The interior [ξ and Tab.17,ρ] ſhooteth out two ſcions, one externall [° and tab.17,ᶠᶠ] called *Muſcula inferior*, the lower Muſcle artery which runneth ouerthwart and is conſumed into the muſcles that couer the outſide of the haunch-bones and the ioynt of the hip. The other internall, [ϖ and tab.17,ᵘᵘ] called *Hypogaſtrica*, which runneth directly downward and ſendeth his ſurcles to the parts of the *Hypogaſtrium* or *Water-courſe*, as the bladder, the wombe, &c. The remainder of this branch [Tab.21.ξ] deſcending [vnder ς] firſt admitteth the vmbilicall artery of his own ſide; after it aſſumeth a portion from the outward branch of the firſt diuiſion [neere ρ;] and ſo increaſed it paſſeth through the hole of the ſhare bone into the leg, and is diſtributed into the muſcles which occupy the ſhare-bone; thirdly in the end it ioyneth [tab.21,ω] with another artery. [↓.] The vtter branch or the ſtocke it ſelfe running downeward accompanied with his veyne whileſt it is yet in the belly [aboue ρ] ſendeth one branch vpward and outward through the cauity of the *Abdomen* called *Epigaſtrica*, [tab.21,ϖ, tab.17, char.22,] vnto the muſcles thereof, and another inward called *Pudenda* [tab.21,ψ tab.17, char.15,] which iſſueth from the Artery ſomtime within the *Peritonæum*, ſometimes without, and runneth along the ſhare-bone, but of theſe we haue ſpoken before in the 15 chapter, and repeated them briefly heere to make better way vnto that which followeth.

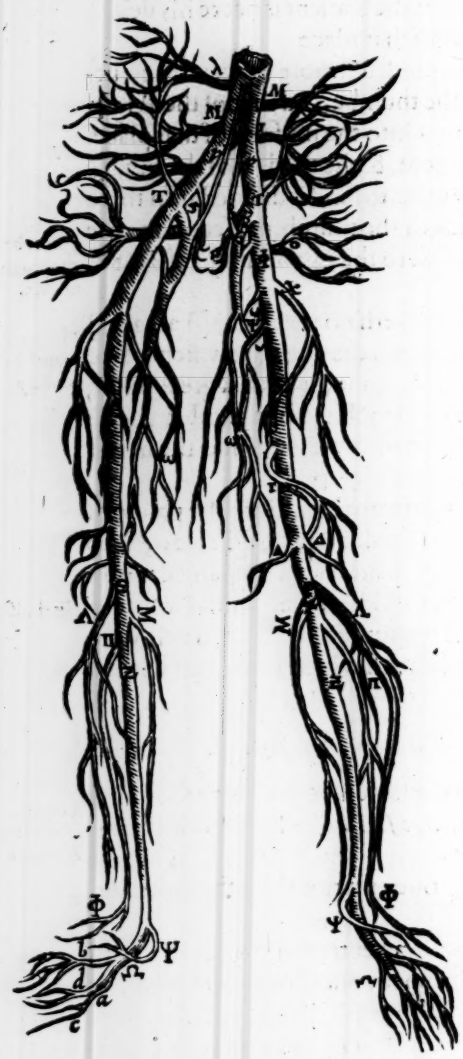
The Iliacke trunke of the great artery when it hath paſſed through the *Peritonæum* and the cauity of the belly into the thigh, is called *Cruralis*, [tab.21,ρ tab.17, char.16.] & from it branches on eyther ſide are propagated and diſſeminated into the whole foot, eight in number.

The firſt is called *Muſcula Cruralis exterior*, the vtter crurall muſcle Artery. [tab.21,χ,] It iſſueth out of the outſide of the crural trunke, and running downeward is conſumed into the foure muſcles that compaſſe the bone of the thigh. *Muſ. Cru. exter.*

The ſecond is called *Muſcula cruralis interna*, [tab.21,Ψ] becauſe it riſeth out of the in- *Muſ. Cru inter.*

Table 21 Sheweth the distribution of the great Artery into both the feete.

TABVLA XXI.



λ, The lower meſenterical artery.

μμ, *Lumbares* which run in knots or knees into the ſpondels of the loynes.

ττ, The diuiſion of the great Artery into Iliack branches aboue the holy-bone.

ξ, the diuiſiō of the right Iliack into an inner branch at ξ, and an vtter at φ.

ο, *Muſcula inferior*, An vtter propagation of the inner branch going into the muſcles couering the ioynt of the *Coxendix*.

π, *Hypogaſtrica*, An inner propagation of the inner branch at ξ, going to the bladder, the yard, and the wombe, &c.

ρσ, the coniunction at σ, of the vmbilicall veyne ρ, with the branch, ξ.

ττ, *Epigaſtrica*, which is ſent vpward into the right muſcles of the *Abdomen*.

υ, *Pudenda*, which creepeth tranſuerſly along the ſhare-bone vnto the priuities.

φ, the externall Iliack branch.

χ, the outward crurall *Muſcle-Artery*.

ψ, the internall crurall *Muſcle-Artery*, which is ſent to the muſcles of the thigh on the inſide.

ω, the coniunction of this Artery with a branch of the *Epigaſtricke*.

Γ, *Poplitæa*, or the artery of the hamme.

ΔΔ, Propagations of the ſurall Artery on eyther ſide going vnto the ioynt of the knee and three muſcles of the foote.

Θ, *Suralis*, the artery of the Calfe which deſcendeth with the inner veine, and is diuided into three branches, Λ Σ Π.

Λ, *Tibiæa exterior* going vntō the muſcles of the foot.

Π Φ, the lower & backer *Tibiæa* hidden within the muſcles attaineth vnder the tranſuerſe ligament to the vpper part of the foot at Φ, and is conſumed into the muſcles of the toes.

ΞΨ, the lower, the trunke of the crurall artery betwixt the heele and the inner artery, to which it offereth a branch marked with Ψ, which runneth to the vpper ſide of the foot.

Ω, the remainder of the Crurall artery going to the toes themſelues betwixt the tendons of their muſcles. *a b*; the diuiſion of the branch Ω, into an inner and vtter branch, *a b*. *c* the diuiſion of the interior branch into 5 to the great toe, fore-toe, and the middle toe. *d* the diuiſion of the exterior branch vnto the middle toe, the little toe, and the next vnto it.

ſide of the foreſaide trunke ſometime anſwering in oppoſition to the former, and is diſtributed into the muſcles which occupy the inſide of the thigh, and falling downe vntō the knee, a ſmal branch thereof is mixed [ω] with the laſt branch of the *Hypogaſtrick* artery.

Poplitæa The third is called *Poplitæa*, [Tab. 21, Γ] the crurall trunke creeping downeward vnder the hamme being accompanied with a large veine maketh this propagation: ſome ſurcles thereof run out into the back-ward muſcles of the thigh, the reſt deſcendeth a good way to the ham-veyne.

Sura'is The fourth is called *Suralis*; the trunke lurking in the hamme or a little vnder it, ſhooteth out on each ſide a deepe propagation, [tab. 21, ΔΔ] which are conſumed, partly in the ioynt of the knee, partly into three muſcles of the foote which make the Calfe and take their originall thereabouts. And theſe are the foure veynes which ariſe from the trunke in the region of the thigh, from hence it deſcendeth to the hamme [tab. 21, Θ] together with the interior veyne, partly to the leg, and partly to the foot; when it is drenched within the muſcles of the leg it is diuided into three notable branches. [tab. 21, Λ Σ Π.]

Tibiæa exterior The fift which is the firſt of theſe three [Δ] is called *Tibiæa exterior*, the outward leg artery. It is a notable branch ariſing from the outſide of the trunke beeing accompanied with the larger branch of the vtter veine, and ſo deſcendeth along the Fibula or Brace, & is conſumed into the muſcles which occupy the leg as far as they are fleſhy.

The

The sixt *Crurall* Artery is the second of the forenamed branches [ta.21.Ξ]and is called *Tibiæa posterior elatior*, the vpper and backer Leg artery. It yssueth a little below the former out of the backer and lower part of the trunk, and descendeth as far as to the commixtion of the tendons of the muscles that make the Calfe, being accompanied with the hinder branch of the *interior* veine. *Tibiæa posterior elatior.*

The seauenth which is the third and last of the aforesayde branches [Ta.21.Π] is called *Tibiæa posterior et humilior*, the lower and backer Leg Artery. It ariseth out of the backeward and exterior part of the trunke, and being accompanyed through the membranous Ligament (with the fore-branch of the inner veine) which ioyneth the *Brace* vnto the *Leg*, it is hidde within the muscles, and runneth forward and downward further then the other two till it passe the transuerse Ligament and attayne to the top of the foote, [Table.21.ϙ] from whence it is disseminated into the muscles that leade the Toes backeward, at which place *Vessalius* and *Platerus* say that the pulse may be easily felt. *Tibiæa posterior & humilior.*

The eight Artery of the Leg is nothing else but the remaynder of the *Crurall* trunke descending along the backeside of the *Tibea* or Leg, [tab.21. the lower Ξ] betwixt the 2. and 3. muscles of the Toes, and so it passeth betwixt the heele & the inner ankle vnto the soale of the foot, but at the inner ankle it offers a branch to the foote, [ta.21.Ψ]which reacheth to the muscle of the great Toe, and creepeth a good way vpon the top of the foot. What the eight artery is

That which is left [Ta.21.ϙ]amongst the tendons of the muscles of the Toes, is deuided into two branches [ab] each of which departeth into 5. furcles: for the inner branch [c] affordeth two to the great Toe, two to that next it, and one to the middle. The exterior [b] offereth two to the little Toe, two to that next it, and one to the middle Toe [d] and the lower side thereof.

And thus much concerning the distribution of the great Artery throughout the whole body. It remayneth that wee come vnto the third sort of vessells which are the nerues, for whose prosecution we haue set aside the third part of this Booke.

The third part of the Eleauenth Booke *concerning the Nerues.*

CHAP. XXI. *Of Nerues in Generall.*

AS the Naturall Faculty together with the Bloud and the thicker Spirit is deriued through the Veines; the Vitall with Bloud and a thinner Spirite through the Arteries as through Canales and Water-courses into all the partes of the body: so the Animall Faculties, that is, of *Sense* and *Motion* are conuayed into those parts which are capable thereof with a subtle and fine Spirite along by the Nerues as it were by the strings of an Instrument.

The Natures, Vses and Diuisions of the Veines and Arteries wee haue vnfoulded in the two former parts of this Booke, and are come in this place to the structure, differences and diuarications of the Nerues.

The Grecians call Nerues τόνους καὶ νεῦρα, the acception of which words among the Phisitians is manifould. *Erotianus* thinketh that *Hippocrates* vsed the word τόνος for all sortes of vessels, Veines, Arteries and Nerues.. *Galen* in his first Booke *de motu musculorum*, in the beginning of his Booke *de ossibus* and in many other places, maketh three kindes of Nerues which appeare without bloud and without any hollownes. The names of Nerues and their kinds.

Of these Nerues some proceede out of Bones, others out of Muscles, others are deriued from the Brayne and the spinall Marrow. Those which yssue out of the Bones & their protuberations are called σύνδεσμοι, *Vincula*, Tyes, Bands or Ligaments. Of these we shall heare particularly in the next Booke. Those Nerues that yssue out of Muscles are parts of the Muscles, and are called ἀπονευρώσεις καὶ τένοντας, that is, neruous propagations and Tendons.

Now a Tendon is nothing else but an excressence or out-growing of the Fibres of a Ligament and a Nerue, which being sprinkled through the flesh doe meete together as it were in one Chord, by which chord the Ioynts are ledde according to the good plea-

sure

ture of our will. The third kinde of Nerues are those which the Phisitians doe properly call νεῦρα καὶ τόνυς, and that from their office; νεῦρα becauſe they doe *nutare ſiue flectere*, that is incline or bend, and τόνοι becauſe they doe *Tendere*, that is, ſtretch. Theſe Nerues do ariſe from the Brayne and the ſpinall Marrow, and are called by *Galen organa προαιρετὰ*, Inſtruments of Senſe and voluntary Motion, becauſe by them the animal Faculty and thoſe that mooue within, that is, the impetuous ſpirites, are conuayed as it were by ſtrings or chords into the particular parts. *Auicen* cals them *Latores*, cadgers in our language. Of theſe *Hippocrates* wrote in his Booke *de locis in homine*, *The whole body is full of Nerues*, that is, throughout the whole body the Nerues doe run from the Braine and the Spinall Marrow, and in his Book *de arte* he calleth them *meteors* in the fleſh, becauſe they are ſprinkled through the fleſh, that is, through the Muſcles.

Compared together.

Galen in his firſt Book *de motu muſculorum*, compareth theſe three kinde of Nerues among themſelues on this manner, A Ligament is inſenſible, a voluntary nerue of moſt exquiſite Senſe, and a Tendon of a middle nature, not altogether inſenſible, becauſe it hath ſome filaments or ſtrings of Nerues therein, neyther yet of ſo quicke a Senſe as is a Nerue.

There are alſo many other parts in the body, which becauſe of the ſimilitude betwixt them and Nerues are called *neruous*, although they cannot bee referred to any of theſe three kinds: ſo we ſay the wombe, the bladder and the guts are neruous, as alſo the vreters, the paſſages of the choller, and the eiaculatory veſſelles. In this place we take the name of a Nerue properly for an organ by which the animall ſpirit and the faculty floweth into the whole body. The nature of this organ may thus be deſcribed.

The deſcription of a nerue

It is a common Inſtrument of the body like a Chord, white, round and long without any cauity which our ſenſe can diſcerne (vnleſſe it bee the Optickes) but porous, in ſome vnited, in the greater nerue made vp of many ſmall ſtrings, & carrying as a Canale and motion which are conducted by the animall ſpirit from the Braine and the Marrow thereof vnto thoſe parts of the body which are capeable of ſenſe and motion.

Their ſubſtãce

Their ſubſtance is white and marrowy, much like the marrow of the braine, from which they take their originall (for I account the marrow of the Braine and the backe to bee of one and the ſame ſubſtance) but more compact and faſter, for it was neceſſary the braine ſhould be very ſoft becauſe it was to receiue the ſpecies or formes of ſenſible things. So that by how much the nerue deſcendeth lower or is more ſeparated from the brain, by ſo muchdoth it become the harder, that it might be better able to endure outward iniuries.

Membranes.

They are inueſted with a double membrane, produced from the two Meninges or Membranes of the braine, the vtter whereof is the thicker produced from the *dura mater* whoſe office is to ſafegard and defend the marrow of the Nerue, and if it conſiſt of many ſmall chords or threds it ioyneth them altogether, and when it hath encompaſſed them about it receiueth into it branches from the neighbour-veines.

Fernelius.

The inner membrane is thinner by much, and lyeth next vnto the marrowe or ſubſtance of the Nerue. It ariſeth from the *pia Mater* and hath the exquiſite ſenſe of touching, which ſaith *Fernelius* it communicateth to the parts whereinto the nerue is inſerted; for as the Braine is couered with theſe two membranes, ſo alſo are the nerues throughout the whole body, a nerue being nothing elſe indeede but a production of the Braine. But this threefold ſubſtance of a nerue, as *Falopius* hath it in his obſeruations and out of him *Bauhine*, may better be diſtinguiſhed by reaſon then by ſenſe, for Anatomy is not able to ſhew the difference betwixt the harde and ſoft membranes of any nerue except it be the optickes.

Which is their chiefe part.

The ſubſtaunce which is in the middeſt or in the center of the nerue is the principall part thereof and performeth the action, for the ſenſatiue and motiue faculty is conuayed from the Braine vnto the parts, not by the coates but by the marrow. Hence it is ſaith *Galen* that if you cut aſunder the marrow of a nerue, preſently the part into which that nerue is inſerted is depriued of ſenſe and motion; as for the membranes they do the ſame office vnto the nerue which they did to the Braine, for the nerues are not properlie the inſtruments of ſenſe and motion (for the immediate organ of motion is a Muſcle) but they are like pipes by which the whole ſenſatiue ſoule and the faculties thereof both of ſenſe and motion are led by the guidance of the Animall ſpirit from the Brayne vnto the parts of the body as they ſtand in neede either of ſenſe and motion, or therefore the Phyſitians do vſe to call them the organs of ſenſe and motion. For they communicate

vnto

vnto those parts into which they are inserted either sense alone, or onely motion, or both together, for no part hath sense or voluntary motion without a nerue; & if the nerue that belongeth to any part be compressed, or intercepted, or cut asunder, or corrupted, the sense and motion of that part doth sodainly perish.

How a Nerue is the Organ of Sense.

Hence it is as *Aristotle* also remembreth in his third Booke *de Historia Animalium*, that no part of the body hath any stupor or dulnesse, any palsie or resolution, any spasme or convulsion that hath not a Nerue in it. Now stupor is a diminution of sense, the palsie a priuation of sense and motion, and a Convulsion is a motion involuntary or against our willes.

The reason of the softnes or hardnesse of a nerue.

Galen In the third and fift chapters of his sixteenth Booke *de vsu partium* sayeth, that those nerues which were made for voluntary motion are hard, and those that were made for sense are soft: and that the softe nerues do make for sensation and the hard for motion, nay he goeth further in the eight chapter of his 7 booke *de Administrationib. Anatom.* and affirmeth that the soft Nerues are onely fit for sense but vnfit for motion. Some again conceiue and not without great reason that the softnesse or hardnes of a Nerue is diuersly occasioned, first from the substance whereout they yssue, and so the first nerues which are saide to arise out of the Braine are the softest, those harder that arise from the spinall marrow, and those hardest of all which arise from the marrow contained in the racke-bones of the Loines and the Holy-bone: Secondly in respect of their production, so those Nerues are soft which run but a little way, as if their iourney be not out of the scul, wher-as those that are led further off as vnto the muscles are harder then they were at their Originall.

In like manner those that run anfractuously, that is, with turnings and windings are very hard, as a branch of the third paire of the Braine. Againe, those are hard which passe thorough a hard body; as that surcle of the fift coniugation which creepeth through the hole of the Temple-bone which the Ancients called *Cœcum* or the blinde-hole is made harder by the contaction of the bone then his beginning was. *Galen* attributeth the cause of hardnesse and softnesse to the counsell of Nature, because, saith he, the instrument of Sense needed a soft nerue; A nerue as a Canale to leade along the Animall and sensatiue spirit, and a soft nerue because it was to be affected and to suffer somwhat from the sensible obiect applying vnto it from without.

Galens opinio.

Nowe, because that which is soft is fitter for pasion; that which is hard for action, therefore, saith he, it was necessary that the instrumens of the senses should haue softe nerues communicated vnto them, and the parts which were to be mooued by voluntary motion should haue harder nerues. And this hee prooueth because vnto those Instruments of sense which haue not only sensation but motion there is a double kind of nerue communicated, one for Sense, another for Motion; as wee see in the eye vnto which the first coniugation is allowed for Sense and the second for Motion, so in the tongue which receiueth the third and fourth coniugations (so Anatomists do vsually distinguish them) for Tasting and the seuenth for Motion.

Bauhines opinion. His reasons.

By the way hence it appeareth, that Nerues beside their vse haue also an animall action because they are affected by the obiect, and therefore the softer nerues are fitter for Sense and the harder for Motion. Notwithstanding all this saith *Bauhine* yet wee conceiue that the nerues of their owne nature are indifferently disposed both to sense and to motion, so that they may be called *Sentientes* or *Motores*, *perceiuers* or mouers from the instruments or parts vnto which they are conducted and in which they are disseminated, for if they be inserted into the instruments of motion, that is, into the muscles, then are they called *Motorij* or mooung nerues. If into the instruments of Sense then are they called *Sensorij* or *perceyuing* nerues; yea we see that one and the same nerue doth conuey motion and sense according to the diuersity of the instruments, for example; the seuenth Coniugation of the Braine conueyeth vnto the Membranes of the bowels which are in the middle and lower belly the Sense of Touching, and yet the same paire being on eyther side reflected makes the recurrent nerue which distributeth surcles into euerie muscle of the Larynx or Throttle to mooue the same. And if the same nerues shoulde meete with the instruments of Seeing, of Hearing and of Tasting, the same perceiuing & mooung nerues would also become seeing, hearing and tasting nerues.

An Instance.

In like manner the nerues which are conueyed to the muscles to affoorde vnto them voluntary motion, do together with that power affoord vnto the membranes of the muscles

cles, into which their fibres do determine, the ſenſe of Touching, and ſo it commeth to paſſe that by the mediation of the nerues, the braine is to bee found in euery part of the body, becauſe the animall faculty which is ſeated onely in the braine, doth notwithſtanding transfuſe it ſelfe through the nerues.

The vſes of the Nerues.

Although out of that which hath been ſaid we may eaſily collect the vſe of the nerues, yet it ſhall not be amiſſe to remember that *Galen* in the ninth chapter of his fift booke *de vſu partium*, and out of him *Veſalius* in the firſt chapter of his fourth book makes a three-fold vſe of them.

The firſt to conuay ſenſe vnto the inſtruments of ſenſation, to the eyes, to the tongue, to the eares, and beſide theſe to the palmes of the hands and the inſides of the fingers, yea to the vppermoſt mouth of the ſtomack alſo, for theſe after a ſence are organs of ſenſation. For the beſt iudge by touching is the hand, and the mouth of the ſtomacke hath an exquiſite ſenſe of the want of aliment which wee commonly call *Hunger*.

The ſecond vſe is to affoord motion to the moueable parts, ſo the muſcles which are the inſtruments of voluntary motion haue nerues conuayed vnto them, and becauſe they were made to moue the whole members therefore their nerues are great and large, and becauſe the ſame muſcles ſtood in need of the faculty of diſcerning Tactile qualities for the ſecurity and preſeruation of our liues, therefore alſo they had nerues by which nerues they haue this faculty of ſenſation.

The third vſe is that for which all other parts haue nerues, to wit, that they might perceiue thoſe things which would be greeuous vnto them: (although this vſe may wel be referred to the former) for ſo wiſe, ſo iuſt, ſo skilfull is Nature ſaith *Hippocrates* (wee ſay the great God of Nature) and ſo prouident for the behoofe of the creatures, that ſhe hath diſtributed nerues to all the parts although not in the ſame meaſure, but to ſome more liberally to other with a ſtrayter hand, and that according to the proportion of their magnitude, of the dignity of their actions, of the intention or remiſsion of their motions, of the aſsiduity or intermiſsion of their vſes. So making an exquiſite eſtimate of the neede of the dignity and of the vſe of euery part, to ſome ſhe hath allowed greater nerues, to ſome leſſer, but to euery one that is fitteſt for it.

The magnitude of nerus.

For there is great difference betwixt the magnitude of nerues; the thickeſt are thoſe which are diſtributed vnto the remoteſt places, and into the moſt parts, ſuch are they that are ſent vnto the ioynts, which becauſe they needed greater aboundance of ſpirits haue a greater proportion of originals of ſinewes granted them out of the ſtocke of the ſpinall marrow which is in the rack-bones of the necke and of the loines, that from their marrow they might receiue a competency of ſpirits as it were by many rootes, which yet being gathered together do make one thicke nerue, but are againe though almoſt inſenſibly diſtributed into leſſer branches. Thoſe nerues are Meane which are conuayed to the organs of the ſenſes in the head: for being neare vnto the braine and very ſoft, they could not be very ſmall. Thoſe nerues are ſmall which are diſtributed into the next parts, as into the muſcles of the face. We will alſo ſay ſomething concerning the originall of nerues.

Their originall.

The originall of the nerues is not from the heart though *Ariſtotle* ſo conceiued in the fift chapter of his third buoke *de hiſtoria Animali*: and in the fourth of his third *de partibus Animalium*, for in diſſection we meete with no nerue produced therefrom, and thoſe that are led vnto it from the ſixt coniugation of the braine are ſo ſmall, that *Veſalius* witneſſeth that he could finde but one, and that with great difficulty.

Neyther haue they their originall as *Eraſiſtratus* thought in his youth out of the *Dura mater* or thicke membrane of the braine as their ſubſtance already declared doth ſufficiently witnes. But as *Hippocrates*, *Eraſiſtratus* when he was wiſer, *Herophilus*, *Galen*, and moſt Anatomiſts do agree from the braine, from which alſo the ſpinall marrow draweth his original. From the brain I ſay, which is manifeſted as wel by ſenſe in the diſſection thereof, where we ſee many riuers of nerues in the braine, to which thoſe of the body are continuated: as alſo becauſe their ſubſtances are marrowy alike and cloathed each of them with two membranes.

Moreouer the affects or diſeaſes of the head doe manifeſtly proue that all Senſe and motion doe flow from the Brayne. So in the Apoplexy which is cauſed by an obſtruction of the paſſages of the Brayne, the Animall Faculty is inſtantly intercepted, albeit the heart be altogether indempnified. So in the Epilepſie or Falling ſicknes where the mar-

row

row of the brayne from whence the nerues do yſſue is affected, the whole body is drawn into Conuulſion, which is nothing ſo when the heart is affected.

An original double.

But we ſayde before that a beginning is double, one of Generation another of Diſpenſation. In reſpect of their Generation their beginning is Seede, of which as of their immediate matter they are framed. In reſpect of their Diſpenſation their beginning is in the brayne, together I meane with the After-brayne, which is the originall *à quo* from which. Thoſe Pipes if ſo you liſt to call them, which receiue Senſe and Motion are diſtributed into the body, as the part ſtandeth in need of the one, or the other, or both.

The differences of nerues.

Againe, the Nerues are ſayde to be of two ſorts, ſome proceeding from the brayne, ſome from the ſpinall marrow, and of theſe againe ſome from the beginning of the Spinall marrow, that is, bei ng yet contayned in the ſcull, others in the Spinall marrow which is in the Rack-bones of the Chine. Againe, of theſe ſome belong to the marrow of the Necke, ſome of the Cheſt, ſome of the Loynes and ſome of the *Os ſacrum* or Holy-bone, to which alſo we may adioyne the nerues of the Ioynts.

Bauhines opinion of the originall of nerues.

Bauhine in this place interpoſeth his owne opinion, which is, that all Nerues doe yſſue from the marrow of the brayne oblongated or lengthned out, ſome whileſt it remayneth yet in the Scull and ſome after. But withall hee maketh mention of diuers opinions both of the Ancient and late Writers concerning the originall of the Nerues, which diſcourſe of his we will here tranſcribe but contract it as briefly as we can. Hee reckoneth therefore eight opinions, for the ninth we thinke not worthy to be remembred.

8. ſeueral opinions quoted by him.

Hippocrates.

The firſt is of *Hippocrates* in his booke *de natura oſſium* in the very beginning, where he ſayth that the original of the nerues is from the Nowle vnto the Spine, the Hippe, the Share, the Thighes, the Armes, the Legs and the Foote.

Ariſtotle.

The ſecond is *Ariſtotles*, who in many places deliuereth that they ariſe from the heart, becauſe in it there are aboundance of nerues (for which hee miſtooke the fibres) and becauſe from thence motions doe ariſe, and vnder his Enſigne *Alexander*, *Auicen* and the whole ſchoole of the *Peripateticks* doe merrit or band themſelues. This opinion of *Ariſtotle*, *Auerhoes* and *Aponenſis* with ſome others doe maintayne indeede, but with a diſtinction, affirming that they iſſue from the hart, *mediante cerebro*, by the mediation of the brayne, or that they ariſe from the heart and are multiplyed and propagated in the brain.

Praxagoras.

The third is that of *Praxagoras*, who thought that the Nerues were nothing elſe but extenuated Arteries.

Eraſiſtratus.

The fourth of *Eraſiſtratus*, who thought they yſſued from the *Dura meninx*, but in his age he changed his mind as *Galen* witneſſeth of him.

Galen.

The fift is *Galens*, who determineth that the Nerues and the Spinal marrow doe proceede from the brayne.

Veſſalius.

The ſixt is that of *Veſalius*, who ſaith that ſome Nerues iſſue out of the Scull, others out of the Racks of the Spine; thoſe that proceede out of the Scull doe ariſe from the *baſis* of the forepart of the braine or from the beginning of the Spinal Marrow before it enter into the ſpondelles. The reſt from the Spinall marrow remayning within the Racke-bones.

Falopius.

The ſeauenth is *Falopius* his opinion in his obſeruations, where hee ſayeth, that ſome Nerues (as thoſe that are ſoft) doe ariſe from the brayne or the marrow within the Scul, others from the Spinall marrow.

Varolius.

The eight is *Varolius* opinion, who ſayth that all Nerues doe take their original from the Spinall marrow which proceedeth from the brayne and the After-brayne, and with him doe *Platerus*, *Archangelus* and *Laurentius* vpon the matter conſent, as alſo doeth *Bauhine* as you haue heard before.

The Nerues therefore which yſſue from the Marrow of the Brayne contayned yet within the Scull are commonly accounted 7 paires according to *Galen*, ſome make nine coniugations which are called *Nerui cerebri* The Nerues of the Brayne, which may be expreſſed in this diſticke.

Optica prima, oculos mouit altera, tertia guſtat
Quartaque, quinta audit, vaga ſexta, ſeptima lingua eſt.

The Opticks firſt, Eye Mouers next, the third and fourth doe Taſt:
The fift doth Heare, the ſixt doth gad, the Tongue claymes ſeuenth and laſt.

To which alſo we may adde the organs of Smelling.

Other

Other Nerues do ariſe from the ſame marrow after it is falne through the great hole of the Nowle-bone and runneth thorough the holes bored in the racke-bones of the ſpine where it is properly called *Spinalis medulla* the *Spinal Marrow*. And theſe are thirty paires or Coniugations, that is to ſay; ſeuen of the Neck, of the Cheſt or backe twelue, fiue of the Loines and ſix of the Holy-bone from which the nerues of the ioynts do ariſe. For the hand receiueth ſometimes fiue, ſome ſixe propagations from the fift, ſixt and ſeuenth paires of the necke, and from the firſt and ſecond paires of the Cheſt: the foot receiueth foure Nerues from the three lower paires of the Loines and from the foure, ſometimes the fiue vppermoſt of the Holy-bone which are called nerues of the ſpinall marrow.

30. pair of the ſpinall marrow

Theſe nerues do yſſue on either ſide after the ſame manner, for no nerue is produced without his companion, and therefore the Grecians called them συζυγία, the Latines *Neruorum paria*, or *Coniugia* paires or Coniugations of nerues. All theſe Coniugations as they do ariſe alike, one from the right hand, the other from the left; ſo are they alſo diſtributed after one and the ſame manner, except onely the ſixt paire of the Braine, whoſe right nerue is not diuided as is the left, as we ſhall heare afterward.

And thus much ſhall haue bene ſufficient to haue ſaid in generall concerning the nature, differences, vſe and originall of the nerues. Now we deſcend vnto their particular Hiſtorie beginning with thoſe of the Braine, becauſe thence all nerues take their Originall.

CHAP. XXII. *Of the Nerues of the Eyes, or of the firſt and ſecond Coniugations.*

The Mamillary proceſſes.

THoſe two proceſſes of the Braine called *Mammillares* which are the Inſtruments of Smelling, do come to be handled in the firſt place, but beecauſe we haue related their Hiſtory and exhibited the Table which belongeth to them in the ſixteenth chapter of the ſeuenth Booke, we will referre the reader for his ſatisfaction vnto that place and proceede vnto the nerues of the eyes, whereof indeede we made ſome mention before, but that briefely and by the way, as alſo we haue done of the reſt of the nerues, becauſe they tooke their Original from the diuers parts of the ſubſtance of the Braine which was then the mayne ſubiect of our diſcourſe.

The nerues therefore of the eyes are of two ſorts: the firſt are called Opticks or *nerui viſorij*, becauſe by them we See. The ſecond are called *Oculorum motorij*, the mouing nerues of the eyes, for by them the eyes are wonderfully and ſodainly moued.

The Optickes are the firſt Coniugation of the Nerues of the Braine [Tab. 22. figure. 1 and 2 °] which are the thickeſt of all the Coniugations of the Braine, yea of all the reſt if they be not compounded of diuers filaments. And ſo much the thicker they were, becauſe ſaith *Galen* in the third chapter of his ſixteene booke *de vſu partium*, they haue ſenſible cauities, beſide of all the others they are the ſofteſt.

The Optick Nerues.

Their original.

They ariſe vnder the middle of the baſis of the Braine, where the marrow beginneth to be lengthned. *Galen* in the third chapter of his ſixteenth booke *de vſu partium* ſayeth, they ariſe from both ſides of the forward ventricles to whoſe ends they are ioyned. Howſoeuer after their originall they run obliquely inward and forward, and when they haue gone a little diſtance, and as it were in the middeſt of their iourny, they are vnited aboue the ſaddle of the Wedge-bone [Tab. 22. figure. 1 H] not onely by interſection or ſimple contaction, but by a confuſion of their marrowes, beeing ſo mingled as they make one common body wherein the two nerues cannot be ſeparated one from another. Preſently after this confuſion they are againe ſeparated [Tab. 22. figu. 1 aboue H] running each of them obliquely outwarde by a hole of the wedge-bone, which was made of purpoſe, commonly accounted for the firſt hole of the ſame, and ſo getting out of the Scull, the right runs vnto the center of the right eye on the hinder part, and the left vnto the center of the left, as if they were the roots of the eyes. Notwithſtanding *Veſalius* and *Platerus* do not thinke that their implantation is into the center, but to the right ſide warde. In bruite beaſtes indeede they are not implanted into the center but much lower, for they looke not ſo much forward as ſideward. Theſe nerues are not diſſolued into Fibres as other nerues are, but are ſpred abroad within the eye, notwithſtanding *Veſalius* ſaith, that he hath obſerued them in Swine to conſiſt of many Filaments, as doe the Nerues of the Legges.

Their confuſion.

Separation.

The

The ſubſtance of the Opticke Nerue is double, Marrowey and Membranous, for the inner part is ſoft, which you ſhall perceiue will ſqueeze out if you preſſe the nerue hard whileſt it is yet compaſſed with his membranes. Their ſubſtance.

Of this Marrowey ſubſtance diffuſed in the orbe of the Eye, is made that coate which is called *Amphibleſtroides* or *Retina tunica*, from the reſemblance it hath with a Net; [tab. 22. fig. 1. and 2.] which notwithſtanding to ſay trueth, is nothing leſſe then a coate, becauſe it differeth nothing at all from the ſubſtance of the brayne, compaſſing the vitrious humour round about and the middle part of the Eye, that ſo the viſiue ſpirites might bee diffuſed through the cauity thereof. *Retina tunica.*

The membranes of the Optick Nerues are two: one from the *Pia mater* and another from the *Dura mater*, notwithſtanding from their originall to the hole which is in the orb of the Eye and wherethrough they paſſe they are inueſted onely with the *Pia mater*, from thence to the eye it ſelfe they aſſume another inuolution or veſtment from the *Dura Meninx* which alſo is conſumed into the horny coate as the membrane they haue from the *Pia mater* is ſpent into the grapie. Hence it is that by the continuation of this nerue in a very moment of time the Animal ſpirit is conuayed vnto the *Pupilla* or apple of the Eie, which is nothing elſe but the perforation or hole of the grapy coate. And therefore when one eye is ſhut we may eaſily diſcerne that the *Pupilla* of the other will be ſuddenly dilated, becauſe of the affluence of the ſpirits. And by this demonſtration *Galen* in the 4. chapter of his 7. booke *de placitis* maketh it manifeſt euen to the very Senſe, that there is not onely a ſpirit but an Animall ſpirit in the body of man. Their membranes.

If it be demanded why Nature did ſo prouide, that when one Eye is ſhut the ſpirites ſhould all accrew vnto the other. I anſwere, it was to accompliſh the perfection of that Senſe; for the concourſe of ſpirites doe better receiue the impreſsion of the obiect and conuay it to the Senſe with more ſpeede and certainty.

Concerning the counſell of Nature in vniting the Opticke Nerues, many men haue diſputed diuerſly. *Galen* thought it was, that one obiect might not appeare double, which conceite *Veſſalius* diſlikes and ſo doth *Archangelus*, who addeth, that if that had bin the reaſon, the Nerues of Hearing, of Smelling and of the reſt of the Senſes ſhould haue beene vnited in the middle of their iorney, that one audible or odorable thing might not appeare double. Diuers reaſons why the opticks are vnited. Anſwered.

The ſecond reaſon, giuen for the vnition of the Opticks is, that one Eie being put out the creature might ſee with the other; but it is more reaſonable to ſay that Natures firſt intention was, that both the eyes ſhould alwayes remayne ſound.

The third reaſon that when one Eye is ſhut all the viſiue Spirites ſhould haſten vnto the other to make the ſight more acute or ſharp. But it may be anſwered that one Nerue cannot contayne ſo much ſpirits as was in both. He that ſhoots at a marke in a Croſſebow or in a Peece, thinks haply that he ſees more ſharply when he blinks of one eye then when he ſeeth his marke with both, but therein hee is deceiued, for indeede he ſeeth not his marke ſo well, yet is able to lay his leuell better, becauſe hee ſeeth more directly when he lookes through a narrow hole.

The fourth reaſon ſome conceiue to be, that when we are conſtrayned to look through a narrow hole, or by the ſame right line by which both the eyes cannot diſcerne; in ſuch a caſe the ſight of both eyes might be vnited into one: But I doe not thinke (ſayth *Archangelus*) that Nature had any ſuch ſcope in her firſt intention.

The fift and laſt reaſon giuen of the vnition is the moſt probable, and that is, that theſe ſoft nerues might not be put to diſtres inthe middle of their paſſage, wherto ſay the trueth they are in moſt danger, as well becauſe of their notable cauities as alſo becauſe of their ſoftnes for they walke through the moiſter part of the brayne, that is, the lower; and the faculty of ſeeing requires ſuch a cauity and ſuch a ſoftnes. Thus far *Archangelus.* *Archangelus.*

They are called Opticke Nerues, that is, viſiue from their action, becauſe they communicate the viſiue faculty or the ſenſe of Seeing vnto the Eye. They are called alſo by *Herophilus meatus viſorij*, becauſe (ſayth he) they onely are ſenſibly bored, which alſo *Galen* approueth, who ſayth that they are manifeſtly perforated at each end. Many Diſſectors are able to perceiue their perforation in the lower part where they touch the Eyes; but ſayth *Galen* in the fourth chapter of the 7. booke *de placitis*, he that would deſcern the other perforation that is at their originall, muſt obſerue three things. Firſt that the creature which hee diſſects bee great: ſecondly, that the diſſection bee made preſently after The names of the opticks.

death. Thirdly, that the ayer be cleare and lucide where he makes his diſſection. Hee addeth alſo in the ſame place a reaſon why it was neceſſary that theſe nerues ſhould rather be perforated then any other, and that is becauſe theſe nerues do leade along the animall faculty by animall ſpirits or by a ſpirituall ſubſtance. For the reſt they needed onely bee porous without any hole or perforation, becauſe the faculty in them is conuayed not by animall ſpirits but onely by a beaming irradiation. But the latter Anatomiſts with one conſent do deny any ſuch conſpicuous perforation. *Veſalius*, I neuer met with it although I haue cut vp dogs aliue and other large creatures onely for this purpoſe, yea ſaith hee I haue opened the head of a man within leſſe then a quarter of an houre after it was cut off, and haue carefully kept it warme with hot water, and yet could neuer find any ſuch perforation. *Falopius* in his obſeruations. The optickes are not manifeſtly perforated. *Columbus*, No pore or hole may bee ſeene in them neyther in an Oxe nor any greater creature. *Laurentius*, I neuer obſerued any conſpicuous cauity. *Volcher*, The opticke nerue is not made of a ſolid and perforated body, but of many neruous fibres bound and vnited by Membranes.

Whether the opticks be perforated.

Opinions of Anatomiſts.

Thus you ſee that the ſtreame of Anatomiſts runs directly againſt this opinion of *Galen*, and they render a reaſon, for ſay they, their ſubſtance being rare and ſoft, the ſpirit may eaſily paſſe through them vnto the eyes; yea all the ſinewes although they haue no viſible holes yet are they full of ſpirits, for the ſenſe is hindred both by compreſsion and by obſtruction. So if a nerue be intercepted with a band or tye, the part below looſeth ſenſe, for the ſpirits of the vpper part being ſeparated from the lower, there is no communion betweene them, but if the tye be taken away the ſenſe returneth. And hence it is, that when the opticks are obſtructed in that diſeaſe which the Arabians call *Gutta ſerena*, the action of ſeeing is vtterly taken away.

Queſtions concerning the ſpirits in the nerues.

But whether we are to beleeue that in euery nerue there is a ſpirit as there is a ſpirite in the braine, which being periſhed the whole creatnre becommeth ſtupid, and beeing ſtrong or plentifull ſerueth for the ſenſe and motion of the parts; and whether if there bee any ſuch ſpirits they be inbred and ſeated in the nerue of the part, and onely awaked by a meſſage from the braine, or whether at ſuch time as we would moue any member, the motiue ſpirit falleth from the braine into the nerue, we confeſſe with *Galen* in the place before quoted, that we are not able abſolutely to determine.

Bauhine concludeth that theſe Nerues are not onely thicke and of a rare texture inueſted by both the membranes of the braine, and fit to giue way for the tranſportation of the ſpirits, but alſo ſaith he, wee beleeue with *Galen* that they are porous as will eſpecially appeare if they bee ſodden, and *Archangelus* ſaith, that in the coition of the opticke nerues there is a common cauity inſculped out of one into another. We ſay alſo with *Galen* in the eight chapter of his ninth booke *de vſu partium*, that the opticks in dignity are preferred worthily before the mouing Nerues of the eyes, becauſe the principall part of viſion or ſight conſiſteth in them.

Bauhines determination.

Moreouer ſaith *Bauhine* whileſt they are yet in the Scul, certaine branches of the ſleepy arteries do on eyther ſide touch them, which obſeruation he tooke out of *Galen* in the place before quoted.

The vſe of the opticke nerues is one and the ſame according to all Anatomiſts, who heerein do accord with *Galen*, that through them the ſenſatiue ſoule and the viſiue ſpirits are conuayed out of the marrow of the braine into the eyes.

The vſe of the opticks.

The ſecond coniugation of the braine is of the Nerues that mooue the eyes [Tab. 22, fig. 1 and 2. K] diſtinguiſhed from the former coniugation onely by a thin bone. This coniugation is ſmall and fine, much leſſe then the former, and harder becauſe it is to bee inſerted into muſcles. It ariſeth out of the baſis of the marrow of the braine, and ſo runneth forward vnto the cauity of the eye, where it falleth out of the Scull through a proper hole accounted for the ſecond perforation of the wedge bone.

The ſecond coniugation of the eye-mouers. their original.

This hole is not round, as that which was bored for the optickes, but ſomewhat long, faith *Galen* in the eight chap. of his 9. booke *de vſu partium*, becauſe three nerues were to paſſe through it: This, the third coniugation or the ſecond branch of the third paire cõmonly ſo called, and the eight coniugation or the leſſer roote of the fift paire, and therefore *Columbus* and *Archangelus* call it *Fiſſuram orbitæ*, a cleft or chinke of the Orbe of the eye.

Where they paſſe the ſcul.

This mouing Nerue hauing perforated the bone, is faſtned to the Opticke, and diuided

The diuiſion extrin. paire.

uided into good large braunches which are conueyed to the seauen muscles of the eie, saith *Vesalius* and *Platerus* to flue muscles of the eye, and to two of the eye-lid saieth *Columbus* and *Archangelus*; to foure onely of the eye, and that that lifteth vp the eye lidde, saith *Falopius* and *Laurentius*.

Bauhine particularizeth concerning their insertion on this manner.

The first branch climbeth ouer the Opticke, and is disseminated into the muscle that lifteth vp the eye-lid, and the Muscle that lifteth vp the eye. The second, is very conspicuous vnder the Optick and is diuided into many surcles and dispersed into the Muscle which leadeth the eye to the inner angle. The third is bifurcated and inserted in manie strings into that Muscle which draweth the eye directly downeward. The fourth is conuayed into the sixt Muscle which leadeth the eye round, or rowleth it vnto the vtter Angle.

There are also saith *Falopius*, and with him *Laurentius* and *Bauhine*, certaine small and threddy Fibres, which accompanying the Opticke Nerue are disseminated into the externall Membranes of the eye. In some men, though it be not very ordinary saith *Columbus* and *Archangelus* (but *Falopius* and *Laurentius* denyit) some branches are sent from this second Coniugation to the temporall muscle, whence it is that when that muscle is offended the eye partaketh with it, and on the contrary. A consent betwixt the 2. coniugation and the temporal muscle.

The vse of this Coniugation is to conferre the Mouing faculty vnto the muscles & the tractiue faculty vnto the membrans of the eyes. Now the reason why when one eye is moued to one side, the other eye also followeth his motion necessarily, is to be ascribed to the Nerues themselues, which in their originall are continuall, that is, doe imediately ioyne together. And so much of the first and second Coniugations which are the Opticke and mouing Nerues of the Eyes. Now we proceede. The vse.

CHAP. XXIII. *Of the third and fourth Coniugations of the Braine.*

THE third Coniugation [Tab. 22. fig. 1 and 2 t] is sent vnto the muscles of the face and is commonly called the lesser roote of the third payre. But saith *Bauhine*, because it is neuer ioyned with the Coniugation following [Tab. 22. fig. 1 and 2 t with x] neither in the beginning nor in the progresse yet hath nothing common therewith, and because it groweth out of order in respect of all the rest, therefore saith he, it may worthily be called a peculiar Coniugation. It is saide to arise from that side of the basis of the Braine where the spinall marrow takes his originall therefrom. [Tab. 22. fig. 1 p] But *Falopius* in his Obseruations hath it thus and better. It ariseth from the lower and backward part of the marrow of the Braine, or those processes thereof which are called the *Buttockes*. *Bauhine* addeth, that their originall is very small, and runneth directly vnder the basis of the braine to the side outward, and perforateth alone the *Dura meninx* on either hand. Then being fastned to the second paire [Tab. 22. fig. 1 x] it entreth into the orbe of the eye together with it by a perforation common to them both. And is diuided into four branches according to *Vesalius*, *Columbus*, *Platerus* and *Bauhine*. But *Falopius* ascribeth these braunches to the two subsequent coniugations which we haue reckoned but for one. The 3. coniugation. His originall. Diuision.

The first of these [Tab. 22. fig. 2 x] runneth vpward thorough the fat of the eyes and affoordeth a branch to the fift muscle placed in the inner angle which compasseth it vnto the pulley. *Falopius* is of opinion in his Obseruations that this whole Coniugation is bestowed vpon this muscle. But presently after the branch wee made mention of before is bestowed, it falleth through a peculiar hole of the forehead bone to the skin of the forehead to giue it and the vpper eye-lid motion.

The second branch of this coniugation [Tab. 22. fig. 2 O] is lower then the former & running downward passeth through a proper hole grauen for him in the fourth bone of the law, at whose forepart it is diuided into many propagations distributed into the muscles that moue the vpper lip, the Wing of the nose outward into the lip it selfe, and the gums of those teeth that are called *Incisorij* or the *shredders*.

The third branch [Tab. 22. fig. 2 r] issuing thorough the second hole of the vpper iawe, behinde the Caruncle seated in the angle of the eye, attaineth the cauity of the nosthrils where it is consumed into their coate, [Tab. 22. fig. 2 the lower r] and affordeth a branch to the Membranous muscle of the nose which contracteth the wing thereof.

The fourth branch [Tab. 22. fig. 2 q] passing through the fissure which is betwixt the

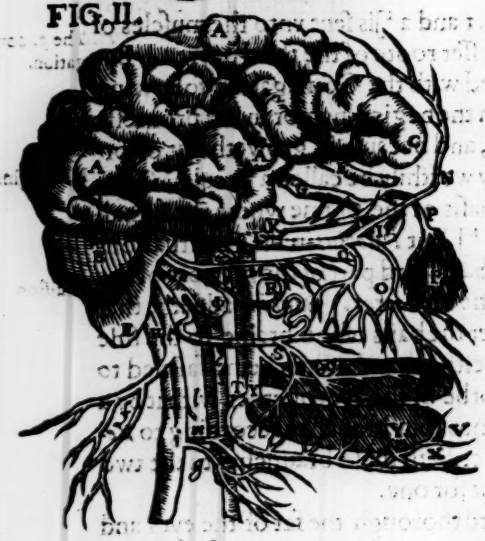
Table 17. Figure 1 sheweth the basis of the Braine and After-braine freed from their Membrane, that the originall of the Nerues of the Brayne might be better perceyued.

Figure 2 sheweth one side of the Braine, the After-braine, the spinall marrow, and the Nerues.

TABVLA XXII.

FIG. I.

FIG. II.



GG 1,2. The Opticke *Nerues*.

H 1, The coition or vnion of the opticke nerues.

I I, 1, 2. The coate of the eye whereinto the Opticke nerue is extended.

KK 1,2. the second paire of sinews ordaind for the motion of the eyes.

LL 1,2, the third paire of sinews, or according to most Anatomists, the lesser root of the third paire.

MM 1,2, the fourth paire of sinews, or the greater root of the third paire.

N 2. A branch of the third coniugation deriued to the musculous skin of the forehead.

O 2, A branch of the same to the vpper iaw.

PP, 2 Another into the coate of the nosethrils.

Q 2. Another into the temporall muscle.

R 2 A branch of the fourth coniugation crumpled like the tendrill of a vine.

S 2, A branch of the same reaching vnto the vpper teeth and the gummes.

T 2, Another of the same to the lower iaw.

V 2, a Surcle of the branch T to the lower lip.

XX, 2. other surcles from the branch T to the roots of the lower teeth.

YY 2, the assumption of the nerue of the fourth coniugation vnto the coate of the tongue.

Z, 1, 2. the 4 paire vulgarly so called which are spent into the coate of the pallat.

a 1, 2. The fift paire of sinewes which belong vnto the hearing.

b, The *Auditory* nerue spred abroade into the cauity of the stony-bone.

A hard part of the fift coniugation aboue the which may be accounted for a distinct nerue.

b 1, 2. A small branch deriued from this harder part of the fift paire.

c 1, 2. A lower branch from the same originall.

d 1, 2. this nerue is commonly ascribed to the fift paire, but indeede is a distinct coniugation which we will call the Eight, because wee would not interrupt the order of other mens accounts.

e 1, 2. The sixt paire of sinewes.

f, 2 A branch from them deriued to the necke, and the muscles couched thereupon.

g 2, another braunch to the muscles of the *larynx* or throttle. *b*, 1, 2 the seuenth paire of sinewes,

i 1, the vnion of the seuenth paire with the sixt.

l 2 A propagation of the seuenth paire to those muscles which arise from the appendix called *Styloides*.

m 2, Surcles from the 7 coniugation to the muscles of the tongue, the bone *Hyois* and the *Larynx*.

bone of the vpper iaw and the wedge-bone is consumed into the temporall muscle. And thus much of the third coniugation.

The fourth Coniugation.

The fourth coniugation belongeth to the tongue and are called *Nerui gustatorij*, because by them the sense of gustation or tasting is made. [*t.* 22. *fi.* 2 M] This coniugation lieth close to the former in the progresse but not in the originall, and is called by them that thinke it hath his beginning from a double roote, it is called I say the thicker root of the third coniugation. It doth not proceed saith *Galen* in the eight chapter of his ninth book *de vsu part.* out of the backe parts of the Braine because those are harde, nor out of the sides because the way had not bene safe; but out of the basis of the Braine where the fore-part is tyed to the hind part, yea out of the marrow of the braine. And the reason of this originall is double: first, because it was most secure, and againe because it was the readiest to answere the position of the tongue; from thence it falleth directly downward thorough the sixt hole of the wedge-bone which is common to this and the following Coniugation, [Tab. 22. fig. 2, Z] and from this presently after the outgate yssueth a propagation

His Original.

on twisted or wrethed like the tendrils of a Vine,[tab.22,fig.1,a] that so,say some,it might by degrees become harder;or rather that the Animal spirit might haue a little stop or stay; and is vnited by two branches [Tab.22,fig.1,and 2,b c] with the auditory nerue. So giuing furcles to the muscles,of the face to the temporall muscles to the grinding muscles of the cheekes and to the skinne of the face.

When it hath allowed this wrinkled branch,it descendeth more downeward and sendeth forth a shoote [Tab.22,fig.2,s] which affoordeth furcles forward to the gums of the grinding teeth,and to the teeth themselues in their order,yet some doubte whither they passe as farre as the rootes of the teeth.

At the same time also there buddeth out of the backside a third propagation which *Falopius* calleth the fourth nerue of the third payre, [tab.22, fig.2,r] which is inserted into the muscle that lurketh in the mouth,and passing through the inner hole of the lower Iaw offereth furcles to the rootes of the lower teeth of his owne side, [Tab.22,fig.2,xx] and by the helpe of these nerues the teeth,whereas other bones haue no sense,do feele the occursation of things that are offensiue. The remainder of this coniugation [Ta.22,fig.2,v] neare the skinne,issuing through a hole bored in the foreside of the Iaw is communicated to the lower lip and to the skin thereof in many furcles.

From this nerue also before it get into the Iaw, there ariseth often a small sinew,slender indeede but strong and long which runneth vnder the Iaw till it come to the muscle which openeth the mouth, and to those which are placed vnder the Chin, and is inserted partly into the bone Hyois and partly into the tongue. The remainder.

Finally,the trunke it selfe [Tab.21,fig.2,r] which *Falopius* in his Obseruations calleth the fift nerue of the third coniugatiō,passeth through the muscles that lurke in the mouth, and beeing accompanied with the trunke of the other hand passeth vnto the side of the tongue and is consumed into the coate thereof to make it a fit organ to discerne the differences of sapors or Tastes,and from it certaine smal furcles are fixed into the substance of the tongue.

From this coniugation that which is commonly numbred for the fourth,by *Galen*,*Vesalius*,*Columbus*,*Platerus*,and *Laurentius* [Tab.2,fig.1,and 2,2] seemeth not to bee distinguished,not because it is neareſt to that before named, but because it taketh his original, though his furcles be many out of one place,and in one place onely perforateth the *Dura meninx*. For those paires or coniugations which are commonly numbred for the sixt & the seauenth although they arise from many propagations,yet because the furcles are vnited together and so vnited do fall through one perforation of the *Dura meninx*,are not accounted for double or manifold paires, for we thinke with *Falopius* that in the distinguishing of the coniugations of the nerues the holes of the Scul are not to be considered;for if this were to be obserued,then because the second and the third payres and the eight do passe through one and the same hole they should bee accounted all for one coniugation, which were yet neuer so accounted by any Anatomist. How to count the coniugations of the sinewes.

The originall of this nerue is lesser then the former neare vnto it and a little harder,& therefore *Galen* saith,that it springeth more out of the Basis of the braine as from a part thereof which is the harder. The originall of it.

Presently after the original,it passeth a little forward and is mingled with the third,with which it issueth at a common hole, and at the pallate is diuided into diuers branches into whose whole coate it is inserted, [tab.22,fig.2,the lower z] and giueth vnto it the sense of Tasting. *Galen* sayth it is somewhat hard because the coate which compasseth the mouth is harder then the tongue and other parts of the mouth; and in this respect his sense is the duller. Sometime two small branches, which descend neare the Almonds and the Appendix called *Styloides* vnto the roote of the tongue are distributed through his coate. And thus much of the fourth coniugation.

CHAP. XXIIII. *Of the Auditory Nerue or the fift Coniugation.*

THE fift Coniugation [Tab.22,fig.1,and 2.a] at the sides of the basis of the braine acording to *Galen*,ariseth out of the marrow of the braine elongated, and is made of two furcles or nerues. The one softer (and indeed the softest except the opticks) and neareſt to the Eare, the other harder. These two do together issue through the membrane & run into the stonybone,& many The fift coniugation.

thinke they are ioyned, accounting them for one nerue, for they say the fift Coniugation consisteth of a soft and a hard part, but indeede and trueth they are distinguished. [ta. 22. fig. 2. It appeareth vnder a] which also *Galen* and *Falopius* did obserue.

His double originall.

This Nerue therefore runneth through a large but writhen hole in the stony-bone, appoynted properly for it, which is numbred for the fift perforation of the Temple bone

His out-gate

into the cauity which is like a Cony-burrough prepared for the Organ of Hearing. Presently after, the harder part runneth forward through a proper Canale or Pipe, being accompanied with an artery arising from that artery which is disseminated through the *dura menin*x, and through the same bone it returneth obliquely backeward, and falleth into that cauity wherein that *Timpanum* or Drum is, yet so that it alwayes buts vpon his owne bony Canale: from thence being more reflected it sendeth forth two shoots, one aboue and another below, both which do passe through by their proper holes. The vpper [ta. 22. fig. 1. and 2.[b]] runneth ouerthwart through the hole, through which likewise a small veine passeth vnto the Organ of Hearing. And this shoote is mixed [ta. 22. fig. 2.[x]] with that branch of the fourth paire, or of the third according to common Anatomists, which we sayd was like the tendrill of a vine: but the lower [tab. 22. fig. 2.[c]] passeth out at a hole which is very streight and writhen, and being carried ouerthwart ouer the *masseter* muscle, is instantly mixed with the branch of the third payre that is like the tendrill of a vine, or to the propagation of the sinew that goeth vnto the Tongue, and from the Tongue is led along to the muscles of the Cheekes, and to the skinne about the roote of the outward eare; and haply this Nerue assisteth the Taste as well as the Hearing, and the reason may hence be deriued why those that are borne deafe are also borne dumbe. Sometimes

His branches vnto the ioynts.

when this Nerue hath gotten through the Blind hole it runneth downward as if it would accompany the sixt coniugation, [ta. 21. fig. 1. and 2.[c]] and sendeth small branches to the proper muscles of the *Larin*x, whence it is that because of the consent betwixt the Eares, the Tongue and the *Larin*x, a dry cough ariseth if we picke our Eares to deep. Sometime also it sendeth small braunches into the whole arme, with the fourth, fift and sixt nerues

The true auditory nerue

of the arme, yea oftentimes it accompanieth the spinal marrow, and sendeth his branches together with the nerues of the marrow into the whole foote. But the soft part of this nerue [table. 22. fig. 2. a] which is indeede *Nervus auditorius* the true Auditory Nerue accompanyeth the hard part, and when it hath attayned vnto the end of the forenamed, cauity it is dilated after the manner of a membrane, [Ta. 22. figu. 1. and 2.[e]] becommeth the chiefe instrument of Hearing, and there remayneth after the same manner that we mentioned before in the expansion of the Organ of Smelling.

CHAP. XXV. *Of the sixt, seauenth and eight Coniugations.*

The sixt coniugation.

THE sixt Coniugation [ta. 22. fig. 2.[e]] taketh his beginning from a few fibres a little below the originall of the fift payre or of the Auditory Nerue. But these fibres are presently and mutually vnited, and are thought to make one great nerue, whereas indeede they are not so vnited but that they remayne a good while two distinct Nerues contayned in one membrane which was the cause of the errour. They get out of the Scull at the second hole of the Nowle-bone by which the greater branch of the internall *Iugular* veine did ascend into the braine. The one of these Nerues is the *anterior* and the lesse, the other is the *posterior* or the greater.

His egresse.

The lesser when it hath gotten out of the Scull descendeth directly vnto the muscles of the Tongue (to whose roote it affoordeth a branch) and to those muscles which occupy the *Fauces* or chops, and into them most part of it is consumed.

The greater Nerue not farre from his egresse sendeth a branch backward, [tab. 22. fig. 2.[f]] which is distributed with many surcles into the muscles that occupy the necke, especially into the Cowle muscle which is the second of the shoulder-blade.

His descending trunke.

The Trunke it selfe descending is connected or tyed to the seauenth Coniugation, [tab. 22. fig. 2.[x]] to the Sleepy artery and to the *internall Iugular* veine, by the interuening or interposition of a membrane, and at the sides of the *Larin*x or Throttle it is increased by a branch from the seauenth Coniugation [tabl. 22. fig. 2.[i]] with which branch notwithstanding it is not mixed (for *Platerus* in this mixtion miss his marke) but colligated or tyed thereto. Presently after it sendeth surcles ouerthwart [ta. 22. fig. 2.[s]] vnto the muscles of the *Larin*x, especially those on the inside thereof. It affordeth also a few small branches distinct from the former to the muscles of the *Fauces* or chops. From thence it descendeth

vnto

vnto the Cheſt and runneth quite through his capacity, as alſo thorough the capacitie of the lower belly, and diſtributeth many branches vnto the bowels of both bellies, as wee haue partly declared already and ſhall do heereafter towards the end of this booke. And becauſe it runneth almoſt through all the bowels of the body it is therefore called *Coniugatio vaga*, the gadding or wandering coniugation.

Falopius tels vs, that the Membrane wherewith this ſixt nerue is inueſted, as it falleth through the perforation aſſumeth vnto it ſelfe ſometime manifeſtly, ſometime ſecretly, a few ſmall and capillary fibres of the nerue, and when it is out of the ſcul, produceth a certaine long bodie reſembling an Oliue, which is ſometimes ſingle, ſometimes double in both ſides, and the colour fleſhy, although the ſubſtance be neruous and hard. *Falopius* his conceit of the Oliue-like bodies.

This *Oliue-like body* endeth into a certaine neruous fibre, which falling down the neck, together with ſome propagations of nerues coupled together which yſſue from the firſt and ſecond, and fourth and fift and ſixt, or from the firſt and ſecond, and fift and ſixte and ſeuenth paires of the necke, doth make a texture or complication of veſſelles like a little net which deſcendeth on either hand downe the forepart of the whole necke; and in that complication, ſaith he, other new Oliue-like bodies do ſometimes grow together, whoſe number is vncertaine, conſiſting of no other ſubſtance but as it were a heape of nerues growing together into a callous or faſt body like a ſcarre. And this coniunction of nerues he calleth *ſexti paris plexum*, the texture or complication of the ſixt coniugation; from which texture many nerues, ſaith he, do deſcend vnto the baſis of the heart. Herefrom alſo very often doth a nerue take his originall which on both ſides is conueyed vnto the midriffe, although it receiue a further increment or encreaſe from the fourth and fift coniugations of the necke. Hee affirmeth further, that from this complication there yſſueth a nerue which deſcending through the Cheſt along the rootes of the ribs is conueyed to the roots of the Meſentery. Thus farre *Falopius*.

Now that from this ſixt coniugation, nerues are ſent vnto the bowelles and not from the marrow contained in the rack-bones this reaſon may be giuen, becauſe hauing not voluntary motion they did not ſtand in neede of ſo hard Nerues as doe ariſe out of the ſpinall marrow properly ſo called; yet that they might not be altogether without Senſe, they receiue Nerues of Senſe, that is, ſoft nerues iſſuing out of the marrow of the Braine whilſt it is yet contained in the ſcull, and the rather ſaith *Galen* in the 11 chap. of his ninth Booke *de vſu partium*, becauſe the ſubſtance it ſelfe of the bowels is but ſoft; but becauſe theſe Nerues were to go a long iourney, leaſt they ſhould be offended they are inueſted with ſtrong membranes, and beſides faſtned to the bodies by which they paſſe. Why the bowelles haue nerues from this coniugation and not from the ſpinall Marrow.

It is alſo worth the obſeruation that the nerues which are diſſeminated from the ſixt coniugation into the trunke of the bodye, are as large almoſt at their terminations after they haue bene diuerſly diuided and ſubdiuided as they are in their originall, which cannot be ſaide of any other veſſell. It hath bene alſo publickly deliuered, I thinke from no other warrant but ſpeculatiue Learning, that this nerue deſcendeth into the ioynts, and in the feete is the cauſe of the great conſent betwixt the feet and the head. For mine own part, I could neuer haue light of any ſuch diuarications out of Claſſicke Anatomiſts: beſide, what neede we ſearch for an imaginary way of conſent, when we know that which is direct and agreed vpon by all, which is the branches of the nerues of the ſpinal marrow, wonderfully vniting themſelues in the Tendons of the Muſcles of the foote; by which any annoyance may at the firſt hand be conueyed vnto the marrow of the backe and ſo vnto the Braine. A notable obſeruation. A notell conceite.

Moreouer, *Galens* reaſon of the allowance of theſe Nerues of the ſixte coniugation to the bowels in the place laſt before quoted were but of ſmall moment if the feet alſo had nerues deriued therefrom. But this onely by the way.

The ſeauenth Coniugation, which *Archangelus* accounteth for the eight, becauſe he maketh the organs of ſmelling a coniugation of nerues: the ſeauenth coniugation I ſay [Tab. 22. fig. 1 h fig. 2 H] mooueth the tongue and is the hardeſt of all thoſe that yſſue out of the Braine within the ſcull, and indeede it taketh his originall from a harder beginning that is to ſay in the hindpart of the Nowle-bone where the marrow of the Braine endeth ſaith *Galen* in the twelfth of his ninth Booke *de vſu partium*. From the beginning of the ſpinall marrow, ſaith *Veſalius*, but before it yſſue out of the ſcull. From the Braine, not from the After-braine, ſaith *Columbus*. *Archangelus* ſaith from the backpart of the marrow where the cauity is that is compared to a writing pen. From the marrow of the Braine, ſayth The ſeauenth coniugation. His originall.

ſaith *Bauhine*, when it is ready to fall out of the ſcull [Tab. 22. fig. 1 & 2 z] that is to ſay, at the very beginning of the ſpinall marrow properly ſo called. Thence therefore it ariſeth with more rootes then one, and thoſe ſomewhat diſtant one from another. But they vnite themſelues and paſſe out of the ſcull by an oblique and proper perforation in the Nowle-bone, and for more ſecurity this Coniugation (ſaith *Galen* in the eleuenth of the ninth *de vſu partium*) is ioyned by ſtrong membranes with the ſixt coniugation, but not commixed therewith ſaith *Falopius* in his Obſeruations. For Retribution it communicateth to the ſixt paire a portion of it ſelfe, [Tab. 22. fig. 2 m] that is to ſay, ſometimes one fibre or ſtring and ſometimes two, but the coniugation it ſelfe keepeth ſtil his owne body, and with a round and full thred runneth downward vnto the tongue, whoſe roote when it attaineth the greater part thereof [Table. 22. fig. 22] is diſſolued or as it were vntwiſted and parted into many fibres, which as ſo many ſurcles are imparted into all the muſcles of the tongue.

His implantation. The leſſer part ſendeth ſome braunches vnto the muſcles of the bone *Hyois* and the Throttle to aſsiſt their motion. It affoordeth alſo ſome ſurcles [Tab. 22. fig. 2 l] vnto the muſcles which take their originall from the appendix which is called *Styloides*. Finally, the Fibers of the greater branch doe ſeeme to be commixed with the Fibres of the fifte Coniugation.

The eight Coniugation. The eight coniugation (if we may ſo call them, which others do aſcribe vnto the fift) [Tab. 22. fig. 1 & 2 d] yſſueth out of the marrow of the Braine aboue the Auditory nerue, (and is much ſlenderer and harder then it) betwixt the ſecond and third coniugations. It runneth vpward and forward vnder the ſides of the baſis of the Braine, and hauing perforated the *Dura Meninx* betwixt the ſecond and thirde coniugations, it getteth into the orbe of the eye through the hole of the ſecond coniugation, ſaith *Bauhine*, according to *Falopius*, although *Veſalius* and *Platerus* thinke it paſſeth through a proper perforation in Implantation the wedge-bone, and ſo goeth vnto the temporall muſcle and that which lurketh in the mouth; but the truth is, that it is almoſt wholy conſumed in that muſcle of the eie which draweth it to the vtter angle.

This coniugation, ſaith *Bauhine*, in regard of his originall ſhould haue bene acounted before the fift and thoſe that follow, but leaſt in changing the number reſolued vpon by Anatomiſts we ſhould breede confuſion, wee haue rather thought good to reckon it *Columbus* his 9 Coniugation. in the laſt place. *Columbus* addeth a ninth paire, of which hee challengeth the inuention, and for ought I know no man is deſirous to take that prize out of his hande, which when they haue they ſhall not be able to hold; but he ſaith that they be very ſmal nerues ariſing from the two proceſſes of the Braine which are called *Nates* or the *Buttockes*, neere the Teſticles; they bend their courſe toward the face, and paſſe out by the third & fourth coniugations and are inſerted into the third muſcle of the eye-lid, but allow a branch alſo to the fift muſcle of the eye. Thus farre *Columbus*.

And ſo much concerning the coniugations of nerues ſeauen, or eight if you will, or nine if you beleeue *Columbus*, which yſſue from the marrow of the Braine contained yet within the Scull. Now we proceede vnto thoſe that yſſue from the ſpinall marrow when it is falne out of the Scull.

CHAP. XXVI. *Of the Nerues which yſſue from the ſpinall Marrow in the Necke.*

THE coniugations before mentioned are called *productions* of the Braine, *and Nerues of the Braine*, albeit they yſſue from the lengthened Marrowe thereof, but yet contained within the Scull. Now we come vnto thoſe ſinewes which draw their originall from the ſame marrow indeed, but that contained in the rack-bones of the ſpine, and therefore are called *Nerues of the Spinall marrow*. For from this marrow all the parts which are vnder the face, excepting the bowels and the inſtruments of the voyce, do receiue Nerues; the bowels and the inſtruments of the voyce do not, partly becauſe it was neceſſary that ſome of them ſhold bee immediately ioyned with the Braine, as the Heart and the Liuer, (for it behooued that all the principles of thoſe faculties whereby the creature is gouerned ſhould be conioyned) partly becauſe their ſituation is neere vnto the Braine, and they ſtande in neede onely of Senſe.

The Nerues of the ſpinall Marrow are accounted thirty Coniugations, yſſuing out of diſtinct

distinct parts and seates, as out of the marrow of the Necke, the Chest, the Loynes, and the Holy-bone contained within their *vertebra* or rack-bones, and issuing out of their perforations or holes thrilled in them. These holes are eyther double before and behind, as in the two first of the neck and fiue of the Holy-bone, or single in each side of the racks, as in the rest.

The coniugations of the necke some account seauen, as *Galen*, *Vesalius*, *Platerus*, and *Laurentius*, yet *Galen* in the fift of the 13 *de vsu partium* reckons 8, and so doth *Archangelus*; *Columbus* but fiue. These are dispersed into the outside of the whole head and his Muscles. 7 of the neck.

The first and second coniugation do not arise after the manner of other Nerues out of the sides of the spondels, one out of the right side, the other out of the left, but one falleth through the hole on the foreside, the other through the hole on the backside, which happeneth because of the different articulation of these two rackes which is so made for the more security of the motion. The first. His diuision.

The first Coniugation issueth betweene the Nowle and the first racke-bone, which that it might more easily be, there is a certaine small cauity in the nowle-bone and in the first *vertebra*, (yet in dogs in whom the spondell is greater, the cauity is onely in it) but before it issue it is reflected aboue the spinall marrow and presently is diuided into two small branches, one *anterior* which is very small, [Tab.23,*] and so small that *Vesalius* saith it is not alwayes visible, but *Columbus* maketh no mention of it at all.

This nerue is inserted into the muscles which lye vpon the necke and vnder the gullet, which bend the neck, accounted by *Vesalius* and *Platerus* for the first payre that moue the backe, but *Bauhine* reckoneth it for the first bender of the necke, and calleth it *Longus* or the *Long-muscle*. Subdiuision.

Table 23 is the same with Table 22. Lib. 7. folio 490.

The other *posterior* [Tab.24,r] which is subdiuided into a double surcle, one lesser which are disseminated into the smal muscles of the head seated in the *Occipitiũ* or nowle, the right branch into the muscles on the right side, and the left into the muscles of the left side, which also we must vnderstand of the nerues that follow. The other surcle of the posterior branch [Tab.24,o] goeth into the beginning of the musele that draweth the shoulder-blade vpward, for being but small they do not run beyond the muscles.

The second coniugation issueth with two beginnings, the fore branch [Tab.23,N] is very small and slippeth out betwixt the first and the second rack-bone at the sides of the tooth, and is distributed into the muscles that sit vppon the neck, as that branch of the first coniugation is, of which we spake ere while, with which branch it is implicated, and so consumed into the whole skin almost of the face. The second coniugation. His double originall.

The posterior branch which is the greater [tab.24,l] when it is issued by the side of the backward processe of the second rack-bone is presently diuided into two vnequal brãches: the thicker [Ta.24,N] runneth ouerthwart toward the middle of the spine where the muscles do meete that occupy the necke, and is increased with a surcle [tab.24,L] of the third coniugation, [tab.23,s] and from the back-part tendeth vpwarde vnto the fore-part of the head, and dispersedh propagations into the skinne of the whole head euen to the top of the whole crowne, yea and vnto the eares; [tab.23, and 24,MM] but the lesser branch [ta. 24, aboue n] is distributed into the beginnings of the third and sixt payres of muscles of the Head.

The third coniugation [Tab.23, char.3.] breaketh out of a common hole which is betwixt the second and third spondell, and is diuided into two branches. The anterior whereof [Tab.23,t] is subdiuided into foure surcles, the first goeth to the first paire of muscles that bend the necke, the second [tab.23, and 24,x groweth with y] runneth downward, and being commixed with a surcle of the fourth coniugation is distributed into the muscles that lye vnder the Gullet. The third coniugation. His diuision.

The third surcle [tab.23,s tab.24, from x to z] runneth vpward and meeteth with a branch of the second coniugation, and is spent into the skin on the sides and top of the head. The fourth [tab.23, and 24,r] is dispersed into the muscles that incline the neck to the sides, as also vnto the muscle that lifteth vp the blade. and subdiuisiõ

Finally, into that quadrangular muscle arising from the fleshy Membrane which draweth the lip obliquely downeward. The posterior branch of the third coniugation [ta. 23, 24, o] is disseminated into the muscles that are common to the head and the necke,

and

and lift it vp which are called *Sacer* and *ſemiſpinalis*. The firſt *Veſalius* accounteth for the ſeauenth mouer of the backe, and the ſecond for the eight.

The 4 coniugation. The fourth Coniugation [ta.23.char.4.] yſſueth out of the common hole of the third and 4. Rack bones, and is diuided ſayth *Columbus* into many ſurcles. *Bauhine* ſayth into 2. branches, an *anterior* & a *poſterior*: the *anterior* which is the greater, is deuided into three propagations. [ta.23.& 24.^{x}]

Diuiſion. The firſt [ta.23.^{r}] is mixed with a branch of the third payre [ta.23.^{x}] and goeth to the muſcles that lye vnder the Gullet, which make the firſt payre of Benders of the Necke.

The ſecond [ta.23.a] departeth into the muſcles that bend the neck into the ſides, that is, into the ſecond payre and to the ſecond muſcle of the ſhoulder-blade called *Cucullaris* or the Cowle muſcle.

The third [ta.23.^{b}] which is leſſer, being accompanyed with a branch of the fift Coniugation, [ta.23.^{c}] and vnited with a propagation of the ſixt [table.23.^{m}] deſcendeth neare the *Mediaſtinum* (where it letteth ſlip a ſmall branch on each ſide) and aboue the *Pericardium*, that of theſe originalles, that is to ſay, the fourth mixed with the fift and the ſixt, the nerue of the Midriffe [ta.23.& 24.^{n}] might be compounded which is inſerted into his neruous tendon called by others his Head. Sometime this branch of the fourth Coniugation is wanting, and then a ſurcle of the ſeauenth Coniugation ſupplyeth the place, but howſoeuer the chiefe part or mountenance of the Nerue is from the fift Coniugation. The *poſterior* branch of the fourth Coniugation which is alſo the leſſe [tab.23.and 24.^{v}] at the ſpine of the third Racke-bone beſtoweth his bleſsing vpon the muſcles of the neck, which lye vpon that ſpondell, and from thence is conſumed into the membranous muſcle of the cheekes.

The 5 Coniugation, his diuiſion. The fift Coniugation [ta.23.char.3.] falling out vnder the fourth ſpondell, is deuided into two branches, one *anterior* another *poſterior*. The firſt ſurcle [ta.23. a^{d} vnto char.6.] of the *anterior* branch [ta.23,and 24.^{d}] goeth to the muſcles which bend the necke. The ſecond [ta.23.^{e}] together with the propagations of the fourth and the ſixt Coniugations [ta,23,out of^{bem}] maketh the nerue of the Midriffe. The third [t.23.and 24,^{f}] runneth vnto the muſcle called *Deltois* which is the ſecond of the arme, from which ſmal branches [ta.24.^{rr}] are afforded to the muſcles that lift vp the ſhoulder-blade called *Cucullaris* and *Leuator*.

From the ſame ſurcles alſo ariſeth another Nerue [tab.23.and 24.^{g}] which with many ſmall fibres is implicated in the skinne that couereth the *Deltois*; another lying deepe at the necke of the ſhoulder-blade is deuided into two branches, the *anterior* [ta 23.& 24.^{h}] and the ſmaller affoordeth ſmall ſurcles to the *Deltois*, where it taketh his originall from the clauicle, ſometimes alſo to the skinne, accompanying the *humerarie* veine.

Table 24. is the ſame with Tab.23. Lib.7. Folio 490.

The *poſterior* which is the thicker [table.23.24.^{i}] firſt ſendeth a ſurcle into the ſecond payre of muſcles of the bone *Hyois* called *Coracohyoidei*: afterward being accompanied with a veine and an artery, it ſendeth another to the vpper *ſuperſcapular* muſcle or the vpper Blade-rider, againe vnto the *Deltois* where it ariſeth from the ſpine of the blade, and finally it ſendeth ſurcles [ta.23.24.^{r}] to the outſide of the skin of the arme: and ſo much of the *anterior* branch of the fift Coniugation. The *poſterior* [ta.24.^{c}] at the tops of the ſpines is reflected and diſtributed like the *poſterior* branch of the fourth Coniugation.

The ſixt coniugation. The ſixt Coniugation which *Columbus* calleth the firſt paire of ſinewes of the hand [ta.23.char.6.] vnder the fift ſpondell where it yſſueth is deuided into an *anterior* and *poſterior* branch.

The *anterior* [ta,23,l] after it hath ioyned a propagation [tab.23,^{m}] to the branch of the fift Coniugation to make the nerue of the Midriffe, is vnited with the ſeauenth of the necke, and the firſt Coniugation of the Cheſt. [ta,23,and 24,^{q}] Afterward it is diuerſly deuided, and with thoſe that follow furniſheth out nerues to be tranſported to the Arm. It ſendeth alſo a peculiar ſurcle [ta,24,^{p}] vnto the hollow part of the ſhoulder-blade into the muſcles that lift it vp.

The *poſterior* branch [ta,24,^{k}] is diſperſed after the manner of the reſt vnto the muſcles which moue the head and the neck, as alſo into the heads of the muſcles which ſerue for Reſpiration, which from the necke doe attaine vnto the Cheſt: thoſe muſcles alſo receiue nerues from the ſeauenth Coniugation and from the firſt of the cheſt.

The

The ſeauenth Coniugation [Tab,23,chara,7,]yſſueth vnder the ſixt ſpondell of the necke, and for more ſecurity is ioyned with the ſixt coniugatio n of the necke and the firſt of the cheſt,[ta,23,r] the chiefe part whereof runneth into the arme, for the nerues of the arme are produced from the fift, ſixt and ſeauenth coniugations of the necke, and from the firſt and ſecond of the cheſt. The ſeauenth coniugation. His diuiſion.

Somtime alſo there proceedeth from this coniugation a branch to the making of the nerue of the midriſſe. Wherefore ſeeing that from the marrow of the necke many nerues do concur to the making of the midriffe-nerue, it is no wonder that in the Apoplexy the motion of the midriffe is for a while naturall, for although becauſe of the obſtruction of the ventricles of the braine, as it is commonly beleeued, the animall ſpirit cannot bee conuayed vnto the midriffe, yet ſeeing that the cauity of the ſpinall marrow containeth ſome deale of animall ſpirits, which by theſe nerues may be tranſported vnto the midriffe, and giue it a little motion, thence Reſpiration remaineth, & though it be but very little, yet the life is thereby ſuſtained as long as the animall ſpirit ſhal remaine in the cauity of the ſpinal marrow, and if the obſtruction of the ventricles can be freed, then he that is apopleticall, returneth to himſelfe, if not there he determines his life. How a man breaths in an Apoplexy.

This is *Bauhines* phyſicke concerning the apoplexy and the cauſe thereof, wherto though I can in no ſort agree, yet becauſe he handleth it but by the way, and we are now in another argument I will not reaſon the caſe with him.

The poſterior branch of the ſeauenth coniugation [tab.24,r] which is alſo the leſſe & neuer miſsing, affordeth ſurcles to the muſcles which lye vpon the neck & vnto the *ſquare muſcles* of the cheekes; into which alſo ſurcles are ſent from the fift coniugation of the braine, and from all ſeauen of the necke excepting onely the firſt, which ſurcles runne according to the courſe of the fibres of the muſcle: they attaine alſo vnto the skinne. It is no wonder therefore if the *Dog-ſpaſme* be a greeuous diſeaſe, ſeeing that this muſcle in it doth at the firſt hand ſuffer conuulſion. The *dog ſpaſme*

Galen in the fift chap. of his 13 book *de vſu partium*, and after him *Archange'us* do adde an eight coniugation iſſuing betwixt the ſeauenth and the eight ſpondell and diſtributed eſpecially into the Cubit and the Ell but paſſeth no further. The 8 coniugation after *Galen* & *Viſal.*

CHAP. XXVII. *Of the Nerues of the Cheſt.*

THE nerues diſſeminated through the cheſt are double as well as thoſe that paſſe through the necke, for ſome take their originall from the braine, or rather from the marrow thereof contained in the Scull, others from his marrow paſsing through the rack-bones of the backe. Of the nerues of the cheſt.

From the marrow of the braine proceedeth the ſixt coniugation of the braine which runneth through the cheſt, of which we haue partly ſpoken before, but will ſay more afterward in this booke.

From the ſpinall marrow contained in the rackes of the backe do iſſue eleuen coniugations ſaith *Veſalius*, but *Bauhine* reckoneth twelue, all which after their egreſſe are diuided into two branches, one greater and another leſſe, one running forward and another reflected backward. Twelue coniugations.

The firſt coniugation [Tab.23, char.8.] which *Veſalius* accounteth the eight of the ſpinall marrow, iſſueth betwixt the ſeauenth rack-bone of the neck and the firſt of the cheſt on eyther ſide and is diuided into two branches, one anterior and another poſterior. The firſt coniugation. His diuiſion.

The anterior which is the greater, after it hath receiued an augmentation [Ta.23,& 24.s] from the ſeauenth coniugation, ſomtime alſo from the ſecond of the cheſt, & is diuerſly commixed with the neighbour ſinewes; attaining vnto the arme-pits, diſtributeth propagations [tab.24,aa] out of his back-ſide into the hollow part of the blade, and ſo runneth away into the arme whoſe diſtribution we ſhall meete withall in that place.

Beſides this, it ſendeth alſo another branch [tab.23,y] vnto the arme, which running forward along the firſt ribbe, and ſo to the top of the breſt bone beſtoweth his bleſsing vppon the firſt muſcle of the cheſt called *Subclauius*, and then is conſumed or ſpent into the muſcles which take their originall from the toppe of the breſt-bone, as the muſcle called *Maſtoides Sternohyoides* and *Oeſophagei*.

The *poſterior* branch [ta,24,u] which is the leſſer, is reflected vnder the muſcles which grow vnto the Rack-bones, and in his tranſition affordeth ſmall ſhoots to the ſecond muſcle of the necke and thoſe that moue the necke and the head backeward; but when it hath attained

attayned the ſpine of the ſeauenth Racke-bone it departeth therefrom and offers ſurcles ouerthwart to the lower part of the Cowl-muſcle, the *Rhomboides* and the vpper & backward ſpine.

The 2. coniugation.

The ſecond Coniugation [tab,24,char,9,]yſſueth betwixt the firſt and ſecond rack of the Cheſt, and as the former it tranſmitteth and diſtributeth a branch backeward [tab 24.ℓ.] Afterward a good part is ioyned with a branch of the firſt coniugation [tab,24.ſ] and runneth into the arme. The remaynder proceedeth according to the length of the firſt rib vnto the Cheſt and maketh the *Intercoſtall* nerue, from which certaine ſmall ſurcles are diſtributed vnto the muſcles that lye vpon the Cheſt.

The 3. and the nine following.

The third and the other nine Coniugations [tab,23,from char,10.to char.20,]of the cheſt are diſtributed after the ſame manner, for after they are iſſued out of the ſides of the Rack-bones, they are deuided into two branches. The *anterior* branches which are called the *Intercoſtall* ſinewes [tab,23,mm] in their paſſage doe offer a ſurcle to the *Coſtall* nerue, which is ſayde to be a branch of the ſixt coniugation of the braine, and runneth vnder the *Pleura* vnto the rootes of the ribs: yea throughout his whole iourney they increaſe it with a ſmall branch. For the branches themſelues runne directly after the bent of the ribbes through the diſtances betwixt them in a proper *ſinus* or cauity inſculped or grauen in the inner and lower ſide of euery rib for the tranſportation of theſe branches, together with a branch of the veine *Azygos* and the great artery which accompany them; and their courſe is forward vnder the *Pleura* neare the *Intercoſtall* muſcles: ſo that the *Intercoſtall* veines of the true ribbes do reach as farre as to the breaſt-bone, thoſe of the baſtard ribbs do attain vnto the foreſide of the *abdomen* aboue the *Peritoneum*.

Their fore branches.

From theſe, diuers branches [ta,23,θθθ and the characters of the left ſide] are diſſeminated into the *Intercoſtall* muſcles as well internall as externall, into the muſcles that lye vpon the cheſt, [tab,23,θθ ıı xx] as the greater and leſſer Saw, the *Pectorall* muſcle and that which is called *Latiſſimus*, [tab,23,ıı] moreouer into the oblique deſcendent muſcle of the *Abdomen*; all which branches immitate the fibres of theſe muſcles. They offer alſo ſmall ſhootes ſprinklingly vnto the skin of the cheſt.

Theſe Nerues as alſo the reſt, of courſe ſhould haue beene inſerted directly into the heades of the muſcles, but nature hath reflected them backeward into the veines, arteries and ligaments of that place. From the lower *Intercoſtall* nerues, ſome ſhootes alſo are communicated [tab,23,ΔΔ] to the muſcles of the *abdomen*.

Finally, from that *Intercoſtal* Nerue which creepeth through the fourth diſtance of the ribs are certain propagations [ta.23,γ] diſſeminated into the *Pectoral* muſcles, from which there yſſue ſome fine and ſmal ſhootes vnto the paps and giuing them a very exact ſenſe. And ſo much for the *anterior* branches.

Their hinder branches.

The *poſterior* which are the leſſer are reflected backward vnto the ſpines of the rack-bones, and lurke amongſt the muſcles that grow vnto them, and are appoynted to moue the Backe and the Cheſt: yet are they not wholly conſumed in theſe muſcles; for when they haue touched the tops of the ſpines, they fall betweene the congreſſe or coniunction of the muſcles of both ſides, and are diſtributed into the muſcles which ariſe from thoſe heights of the Spines, as thoſe that are called *Splenij*, *Rhomboides*, *Cucullaris*, *Latiſſimus*, *Serratus*, *Poſticus inferior*; and ſome are diſtributed into the skinne. But the diſtribution of Nerues into the skinne is not one and the ſame in all bodies, and therefore can neither their order nor their number be certainly defined, for the trunkes are deuided throughout the skin, ſometime into more ſometime into fewer branches.

To conclude, the two laſt coniugations of the cheſt doe offer ſurcles, *Columbus* ſayth to the fleſhy part of the Midriffe: *Bauhine* [ta,23,at the ſides char.18,19] to the head of the muſcle called *Lumbalis* or the ſixt muſcle of the Thigh.

CHAP. XXVIII. *Of the Nerues of the Loines.*

The nerues of the loynes.

THE common & receiued opinion is, that frō the ſpinal marrow contained in rack-bones of the Loines doe ariſe fiue Coniugations of ſinnewes which are greater then the coniugations of the cheſt and yſſue out of the holes of the rackes of the Loines; heerein agreeing with the nerues of the cheſt, that euerie coniugation is diuided into an *anterior* and a *poſterior* branch, and that from the *poſterior* branches [Tab.24. char.52,53] propagations are diſtributed into the muſcles that grow vnto the rackes of the Loines. Among themſelues they haue this alſo common ſaith *Galen*, that they are diſſeminated into the ſpinall muſcles, the *Abdomen* and the fleſh of the Loines.

5. coniugatiōs

The

The first coniugation [Tab. 23. char. 20] as also the rest issuing at the hole of the spondell vnder the Rim is diuided into two branches, one *anterior* and greater, from vvhich surcles are sent into the fleshy parts of the Midriffe, others vnto the head of the Muscle called *Lumbalis*, others vnto the muscles of the *Abdomen*. The *posterior* braunch is the lesser and reflected into the muscles which lye vpon the rackes of the Loines whereinto it is consumed as are the Surcles of the following coniugations. Such are the muscles called *Sacrolumbus*, *Longissimus* and *Sacer*. But where they yssue from the tops of the spines they run into the sides and are disseminated into the skin of the arme and the broade Muscle called *Latissimus*. The first coniugation.

The second coniugation [tab. 23. char. 21] runneth vnder the sixt muscle of the thigh called *Lumbalis* vpon which it bestoweth small branches afterward: arising vppe vnto the top of the hanchbone the *posterior* propagation therof passing the *Abdomen* doth afford Sense and Motion to the first muscles of the thigh which make the buttockes, and to the first extender of the Legge called *Membranosus*. But the *anterior* branch is distributed into the seuenth muscle of the thigh according to *Vesalius* and *Falopius*, but the sixt according to *Bauhine* and *Columbus* called *Iliacus internus*; into the first bender of the legge and vnto the skin of the thigh. From this coniugation also yssueth a small and long Nerue, [Tab. 23. char. 49] which together with the spermaticall vesselles of his owne side is conuayed vnto the Testicle, which Testicles also receiue surcles frō the *Costal* or rib-branch of the sixt coniugation of the Braine. The second.

The third coniugation [tab. 23. char. 22] yssueth also vnder the *Lumbal* Muscle. His *anterior* braunch passeth neere the haunch-bone and is diuided into two propagations; One of which goeth vnto the knee and the skin thereof, the other accompanieth the vein called *Saphena*. But the *posterior* branch is reflected and disseminated into the Muscles that lie vpon the Loines and into the skin. In like manner from the *anterior* branches of the three first coniugations certaine surcles [tab. 23 at the sides, charact. 20, 21, 22] apply themselues vnto the costall nerue and are ioyned therewith. The third.

The fourth coniugation [Tab. 23. char. 23] which is the greatest of all the paires of the Loines, runneth vnder the *Lumbal* muscle and the share-bone accompanying the vein and artery vnto the groine. *Columbus* obserueth, that it sendeth some propagations into the cod and the skin of the yard: but we, saith *Bauhine*, haue obserued that those partes do receiue small sinewes from the marrow of the holy-bone as *Galen* noted in his seuenteenth Booke *de dissectione Musculorum*, and after him *Archangelus*. It distributeth also other propagations. *Columbus* reckoneth seauen, vnto the *anterior* muscles of the thigh and the legge, from which some surcles do descend as farre as to the knee.

The fift coniugation [tab. 23. char. 24] like the rest is diuided into two. The *anterior* and greater branch passeth through a hole betwixt the bone of the *Coxendix*, of the share and of the hanches, and distributeth propagations sometimes to both the muscles that compasse or bend the Thigh about; sometimes vnto the seuenth and eight benders of the Thigh, sometimes vnto the muscles of the yard, though commonly they receiue nerues from the marrow of the Holy-bone. Item, branches vnto the neck of the bladder & of the wombe which also receyued nerues from the marrow of the Holy-bone. But the *posterior* branch is reflected and consumed into the muscles that sit vpon the rackes of the Loines and into the skin of that place. Finally, from the three lower coniugations no small number of branches do reach vnto the Leg; as in that place wee shall not forget to remember.

Moreouer, these coniugations are hard and fastned one with another, the first with the second, the second with the third, the third with the fourth, the fourth with the fift, as it is demonstrated in the first figure of the 23 Table; after the same manner altogether as the Nerues of the arme are implicated one within another. The connexion of these coniugations.

CHAP. XXIX. *Of the nerues of the Holy-bone.*

OVt of the marrow concluded within the racles of the Holy-bone doe yssue sixe coniugations of Nerues. *Galen* reckoneth three of the Holy-bone, and three of the rumpe-bone. But *Vesalius* and *Columbus* do heerein reprooue *Galen*, with what euidence of truth I cannot say, it appeareth manifestly that he was not ignorant of those bones euen in the bodies of men. Sixe coniugations of the Holy-bone.

The first Coniugation [Tab. 23. char. 25] yssueth betwixt the last racke-bone of the The first.

loynes and the first of the Holy-bone after the same manner as it was in the coniugations of the loynes, and is diuided into an *anterior* and a *posterior* branch. The Anterior branch, although the greatest part thereof be mixed with the Nerues which are conueyed vnto the legge, yet notwithstanding it sendeth a propagation [Table. 23. char. 53] vnto the inside of the hanch-bones from whence surcles are offered to the Muscles of the *Abdomen* and the seuenth muscle of the thigh which is called *Iliacus internus*. The posterior branch runneth after the same manner as do the other Coniugations, and shopteth a propagation [Tab. 24. char. 54] into the muscles produced from the haunch-bone, especially into the first moouer of the Thigh from whence issue surcles consumed into the skin of the buttockes.

The fiue last. The fiue subsequent Coniugations [Tab. 23. from char. 26 to 30] are produced after one and the same manner: for before their egresse they are on both sides double and on either side one Nerue falleth forward, and on either side one Nerue backward. The three vpper Anteriors or forward nerues, as also that of the first coniugation, doe run vnto the legge: the two lower vnto the muscles of the fundament and the bladder, haply also to the priuie parts, in some bodyes vnto the Necke of the Wombe, of the bladder, and of the yard. Finally, others are conueyed vnto the *Perinæum*, that is, the place betwixte the Cods and the Fundament, and vnto the cods themselues.

Their anterior branches.

Their posterior branches. The Posterior branches [Tab. 24. char. 54, 55] are distributed into the muscles which take vp the *posterior* part of the hanch and holy bones; into the muscle of the backe called *Longissimus*; into that which is called *Sacer* or the holy Muscle; into the Membranous beginning of the broad muscle of the Arme and the sixt of the Chest called *Sacro lumbus*: finally into the foure extenders of the thigh, and into the skin of the buttockes.

But the termination or end of the spinall Marrow [Tab. 23 and 24. ch. 56] yssuing out of the Holy-bone doth on either side part with a propagation which sometimes is distributed into many surcles on the right hand and on the left, which is disseminated through the fourth muscle of the thigh through the skin which is betwixt the buttockes euen vnto the fundament: yet some say that it is distributed as other nerues are, and call it *Nerum sine coniuge* the Nerue without a companion: and thus it is in man. But in Apes & Dogs there are three Coniugations of which the two lower onely are produced forwarde and backward; the rest of the Coniugations yssue out at the sides of the rumpe bone, as they do out of the rackbones of the Chest and of the Loynes.

The sum of al From this History of the Nerues of the spinall marrow we conclude that it hath thirty coniugations or paires of Nerues, seauen of the marrow of the necke, twelue of the marrow of the backe or of the Chest, fiue of the marrow of the Loynes, six of the marrow of the Holy-bone. And all these with their seuerall originals, places of egresse and distributions, not onely Physitians but Surgeons also ought necessarily to knowe that they may be able to apply their Vnguents and Cataplasmes vnto the right places of the spine or ridge when either the Nowle, or the face, or the necke, or the hands, or the partes of the chest, or the muscles of the *Abdomen*, or the wombe, or bladder, or the fundament, or the yard, or the legs shall be depriued of motion or sense, or both together. Thus much concerning the nerues of the spinall marrow, and the parts thereof.

How necessary the knowledge of this is for Chirurgeons.

CHAP. XXX. *Of the Nerues of the Hand in the large acception.*

The Hand, THE Hand is the Instrument of Instruments; that is to say, the Instrument of the minde or Soule whereby she frameth and fashioneth all Instruments which consist of any matter whatsoeuer, or haue respect vnto any commodity or profit of man. And therfore that it might more freely do the seruice it was ordayned for; it hath in allowance not only muscles the instruments of voluntary motion, and veines which conuay bloud and nourishment vnto it, and arteries to giue it vigour and viuacity: but also it hath nerues as wel to conuay the motiue vertue vnto the muscles, as also to furnish it with the most exact sense of touching. There are therefore disposed vnto the Hand sometimes fiue payres of sinnewes, sometimes sixe, arising from the spinall Marrow contained in the racke-bones of the Necke and Chest, that is to say out of the fift, sixt and seuenth of the Necke, and the first and second rackes of the chest. These Nerues do yssue out of the common perforations of the aforesaid rackbones, and presently after their egresse are vnited at the sides of the spondils: afterward, they are separated, againe conioyned, and finally separated, so seeming to make the meish

Hath 5 paire of sinewes.

of

of a net, [tab.25,fig.3,] or saith *Columbus* and that out of *Vesalius*, it is like the strings of a Cardinals hatte. This implication was made for more security that the nerues which were to walke a longer iourney might become harder, and so stronger to propulse or endure any iniury that might be offered vnto them.

These nerues run vnder the clauicle or cannell bone vnto the inner processe of the shoulder-blade, where the Basilica veyne and the Axillary artery keepe their way, and hence it is that wounds in this place are so very dangerous, and luxations of the shoulder do easily bring a consumption vppon the Patient. Why wounds about the clauicles are dangerous, and the luxation of the shoulder.

From this fore-saide implication or complication of the sinewes do the nerues of the hand or of the arme arise, and creepe betwixt the skinne and the fleshy membrane deeply drenched in fatte in the bodies of men, and by their mediation that fleshy membrane is indissoluebly fastened to the skinne, but they do not alwayes retaine the same magnitude, position and number; alwayes they are distributed into many backward branches, but the greater nerues Nature hath worthily distributed into the insides of the hand becausse by them it performeth all his actions.

The first nerue of the hand is a surcle of a branch of the fift nerue of the necke [tab.25. fig.1,] which runneth through the vpper and external part of the arme, [tab.25,fig. 1 & 2. f] and is diuided into two branches. The one vpper, which is sent vnto the muscle called *Deltois*, [Tab.25,fig.1,and 2,h] from which a branch [tab.25,fig.1,and 2,g] is communicated to the skinne that lyeth vppon the same muscle being accompanied with the humerary veyne. The other being accompanied with a veine and an artery, at the sinus or bosome of the blade passeth on vnto the second muscle of the bone *Hyois* called *Coracohyoideus* which occupieth the vpper part of the shoulder-blade, and to a part of the *Deltois* & the skinne of the middle of the arme on the vpper side, [tab.25,fig.1,and 2.i] and maketh the first nerue of the arme. [tab. 25,fig.1,ππ] It determineth a little vnder the middest of the length of the arme. The first nerue of the hand.

The second nerue of the hand [Tab.25,fig.1,ρ] is bigger, and taketh his beginning from the complication which the nerues that are to goe vnto the arme doe make at the sides of the rackbones. Thence it falleth by the anterior and middle part of the Cubit, and first of all communicateth a small branch to the muscle called *Biceps* which is the first of the Cubit: [tab.25,fig.1,ss] afterward it ioyneth with the the third nerue, [Tab.25,fig.1,& 2. τ] and after the coniunction it creepeth downeward, [Tab.25,fig.1,ω] and from the outside sendeth a small branch [ta. 25,fig. 1,Γ] to the muscle of the Wand called *Supinator longior*. But when it hath attained vnto the bent of the cubit it is diuided into three branches, (somtimes into two, but then the lower is againe subdiuided) one vpper and smaller, [ta 25,fig. 1, creeping from the vpper ª vnto the lower ª] which passing a good way by the outside of the arme with a branch of the humerall veine runneth vnto the outside sometime of the first somtime of the second ioynt of the thumb, and intertexeth that part with small surcles. The second [tab.25,fig,1,Θ] is the middle-most and something larger then the former. It lyeth vnder the foresaide humerall veyne where the Median or Common veyne ariseth thereout (and descendeth with an oblique passge along the cubit, but aboue the fleshy pannicle) euen vnto the wrest. [ta.25,fig-1,Λ aboue 44] The third is the lowest. [ta.25,fig.1,ΞΞ] His progresse is somwhat oblique and is fastened to the interior branch of the Basilica veyne, & in the cubit is diuided into two branches, [ta. 25,fig.1,ΠΣ] at length ouercomming the wrest it distributeth surcles to the skinne on the inside of the hand, frō which somtimes smal shootes do attaine vnto the outside of the thumbe, which are commixed with th surcles of the posterior branch. The second. His diuision into three branches.

The third nerue of the hand [ta.25,fi.2,τ] runneth through the fore and lower side of the cubit and vnder the *double-headed* muscle in the arme is increased with a branch of the second nerue. [ta.25,fig.1,Ψ] Presently after it is diuided and affoordeth two branches to the skin on the forepart of the arme [ta.25,fi.1 υ betwixt τ and χ.] When it hath attained vnto the bent of the cubit, it is mingled with the fift payre, [ta.25,fig.1,ch.43,] & sendeth small branches vnto the muscles which grow out of the inner protuberation of the arme: from hence it reacheth a notable branch obliquely to the *Radius* or wand, [ta.25,fig.1.ch. 44,] which being accompanied with a veine & an artery is parted into 3. and runneth into the inside of the hand, communicating 2 surcles to the thumbe, two to the fore-finger, & one to the vpper side of the middle finger. And when this middle finger doth not receiue a surcle from the fift nerue, then it alloweth two to the middle and somtimes one to the Ring-finger. The third.

Table 25. Fig. 1 & 2 ſheweth the Nerues of the whole hand, the firſt figure ſheweth their foreſide, the ſecond their backſide.

FIG. III.

A, the ſpinal marrow getting into the Rackbones.

charact. 1,2,3,4,5,6,7,8,9. Seauen rackbones of the necke and two of the Cheſt.

c 2 the hinder branch of the fiſt paire.

d 1.2, the forward branch of the fiſt payre.

f 1,2, A branch of the nerue *d* creeping to the top of the ſhoulder, vnder which are ſurcles going to the ſhoulder-blade.

g 1,2, Propagations of the nerue *f* going to the skin of the top of the ſhoulder.

h 1,2, A branch of the nerue *f* going vnto the ſecond muſcle of the arme.

i 1,2, Another branch inſerted into the ſame and to the skinne.

charact. 6, in 1, the ſixt coniugation of ſinewes

k 2, the hinder branch of the ſixt paire.

l 1, the fore branch of the ſixt payre.

m 1, A ſurcle thereof that maketh the nerue the midriffe.

p 2, A branch of the ſixt payre reaching vnto the cauity of the ſhoulder-blade.

q 1,2, the complication of the branch *l* with the neighbour branches.

char. 7, in the firſt fig. The ſeauenth paire of nerues.

r 2, The hinder branch of the ſeauenth payre.

ſ 1, the congreſsiō or meeting of the ſeuenth payre with his neighbour branches.

ttt, Some ſurcles hereof going vnto the muſcles of the ſhoulder-blade and the arme.

u 2, the hinder branch of the eight payre.

x 1 2, the coition or meeting of the 8 payre with the ſeauenth.

y 1, A branch of the eight payre going to the top of the breſt, *aa* 2, Surcles from the eight payre going vnto the muſcles of this place. char. 9, in the firſt figure, the ninth payre of nerues. *β* 2, the hinder branch of the ninth payre. *Λ* 1, the fore branch of this coniugation. *γγ* 1, the firſt nerue of the arme going vnto the skin. *ρ* 1, 1, the ſecond nerue of the arme. *ττ* 1, Frō this do proceede nerues going vnto the firſt muſcle of the Cubit called *Biceps*. *τ* 1 2, the third nerue of the arme *υ* 1, A branch thereof to the skin of the arme. *φ* 1, A ſmall branch going vnto the ſecond muſcle of the Cubit called *Brachiæus*. *χ* 1, to the skinne of the foreſide of the arme. *ψ* 1, the meeting of the third nerue with the ſecond. *ω* 1, the ſecond nerue together with the third creeping downeward. *Γ* 1, A nerue to the ſecond muſcle of the *Radius* called *Supinator longior*. *Δ* 1, the diuiſion of the ſecond nerue into three branches. EE 1, the vpper or firſt branch of the ſecond nerue running vnto the wriſt and ſo vnto the firſt ioynt of the thumbe. *Θ*, the middle branch of the ſecond nerue. *Λ* 1, His progreſſe euen vnto the hand. *Ξ* 1, the lower and third branch of the ſecond nerue. *Π Σ* 1. two branches of this nerue going vnto the inſide of the hand. *Φ* 1,2. The fourth nerue of the arme. *Ψ* 2, Nerues from this vnto the extending muſcles of the Cubit. *Ω*, A branch vnto the skinne on the backſide of the arme. 32, 2, to the skinne on the outſide of the arme. 33, 2, A branch creeping along the outſide of the Cubit vnto the wreſt. 34, 2, the bypartition of the fourth nerue at the cubit. 35, 2, the vpper branch of the ſaide diuiſion. 36, 2, the ſurcles which belong to the thumbe, the forefinger, and the middle finger on their outſide. 37, 2, the lower branch of the foreſaide diuiſion. 38, 2, Surcles therefrom vnto the muſcles ariſing from the externall protuberation of the arme. 39, 40, 41, 2, three branches going to the muſcles that ariſe from the *Vlna* or *Ell*. 42, 2, the end of the branch 37 neare the ioynt of the wreſt. * 1, 2, the fift nerue of the arme. 43, 1, Propagations of the third and fiſt nerues, vnto the inſide of the Cubit. 44, 1, A branch of the third nerue going vnto the palme of the hand and the fingers. 45, 1 A branch of the fiſt nerue vnto the inſide of the hand. 46, 1, A propagation of the branch 45 vnto the outſide of the hand. 8, 1, 2 The ſixt nerue of the arme. 47, 1, His end neare vnto the ioynt of the hand. 48, 48 1, Surcles from the ſixt nerue vnto the skinne.

Fig. 3. Sheweth the complication of the Nerues which come vnto the arme out of Veſalius.

Char. 5, 6, 7, 8, 9, The rootes of thoſe coniugations from which nerues are produced vnto the arme. A A portion of the fiſt payre or the firſt nerue. B, the ſecond nerue. C, the third nerue. DD, the fourth nerue which iſſueth out of the backſide of the congreſſe or coniunction of the fiſt payre and the sixt, it aſſumeth a portion out of the backſide of the coniunction of the ſeauenth payre, and after creeping vnder the coniunction of the eight and ninth payres, it alſo aſſumeth a portion therefrom. E, Which is the branch marked with E. F, the fiſt nerue that runneth into the arme. G, the ſixt nerue deriued into the arme.

The

The fourth Nerue [tab.25.figu.1,and 2,*]which is the largeſt of all the Nerues that runne into the Arme,taketh his beginning from the complication we ſpake of before. It runneth along the backeward and vpper part of the cubit ouer the externall protuberation of the arme,and paſsing along with the *Deepe-veine* and the Axillary artery,it inflecteth it ſelfe at the vtter and backepart of the arme, and diſtributeth two branches to the extending muſcles of the cubit[ta.29.fig.2.*]and to the skinne which is at the ioynt, and vnto the backepart,and another vnto the vtter part. [ta,25,fig,2,n and char,32,] Afterward neare the ioynt of the cubit at the externall protuberation of the arme [tab,25,fig2, char,34,]it is ſometimes deuided into two trunkes which lye deepe as doeth their roote; [char,35,37.]ſometimes it is diuided into three branches, [char,33,35,37,] whereof the exterior [ta,25,fig,2,char,33,]runneth along the outſide of the cubit whereuppon it beſtoweth branches and deſcendeth obliquely to the wreſt. The fourth. His diuiſion.

The ſecond which is the higher [ta,25,fig,2,ch,35,]runneth throughout the length of the wand vnto the outſide of the Hand [ta,25,fig,2,char,36,]and is conſumed or ſpent into two ſurcles which paſſe vnto the thumbe, two into the fore-finger and one into the middle finger.

The third [char,37,]deſcending by the length of the *vlna* or Ell, affordeth ſurcles to the muſcles that extend the fingers [chara,38,39,40,41.] and is conſumed or ſpent into the outſide of the wreſt intangling with ſome ſurcles at the roote thereof [chara,42,] the ioynt of the wreſt with the cubit.

The fift nerue of the Hand[ta,25,fig,1,and 2,*]taketh his beginning from the foreſayde complication, and being faſtned to the fourth runneth betweene the muſcles that extend and bend the cubite, (yet diſtributeth no branches to the *Radius* or wand) on the backeward and lower ſide thereof; and when it attayneth to the inner cauity of the proceſſe or protuberation of the arme, at the foreſide of the cubite it is a little reflected,and affordeth propagations [ta,25,fig,2,char,43,] to the muſcles which ariſe from the inner protuberation of the Arme,as alſo from the Ell and the wand, which muſcles doe not receiue any ſurcles from the third nerue. The 5. nerue. The ſecond.

From thence paſsing with a notable branch and being accompanyed with a veine and an artery it is faſtned to the Ell,and in the middle of the cubit is deuided into two braunches, [ta.25,fig,1,char,45, and 46,]one internall [char.45,] which is conuayed by the inſide of the Ell,amongſt the muſcles that bend the Fingers, & accompanyed with a veine and an artery is conducted vnto the wreſt,and vnder the tranſuerſe Ligament thereof vnto the palme of the Hand,where it ſendeth two ſurcles to the little finger,two to the middle finger,and one to the ring finger on their inſides. His progreſſe

The other externall branch[char,46,]at the middle of the Ell ſhooteth out a propagation from his outſide, between the muſcle that bends or extends the wreſt, which propagation runneth along the Ell,and is lengthned to the outſide of the cubite, and at the outſide of the wreſt beſtoweth two ſurcles on the litle finger, two on the ring finger and one on the middle finger. But wee muſt remember that the inner braunches are larger then the vtter, becauſe the vtter may more eaſily bee offended. Sometimes from this fift Nerue there are no ſurcles diſtributed to the inſide of the hand: ſometimes alſo the outſide of the inner part of the middle finger and the inſide of the ring finger do obtaine ſurcles from the third nerue,and then the fift doth onely exhibit two propagations to the inner part of the litle finger,and one to the inner part of the ring finger.

The ſixt Nerue,[ta,25,fig,1,and 2,*] which in bigneſſe is anſwerable to the ſecond where it attayneth to the cubit, creepeth through the inner and lower ſide of the Arme & of the cubit as far as to the hand, [ta,25,fig,1,char,47,]and neare the inner protuberation of the arme diſtributeth many ſurcles on each ſide into the skinne of the cubit;[Tab. 25,figure 1 char,48,] which ſurcles doe ſometimes lye vnder the branches of the *Baſilica* veine,ſometimes aboue them, and it determineth not farre from the connexion of the wreſt with the cubit [Ta,25,fig,1,char4*.] The ſixt.

Here we muſt note that which we touched before in the 24,Chap.that with the fourth, fift and ſixt Nerues of the Hand oftentimes there are mingled certaine ſmall braunches yſſuing from the fift Coniugation of the Brayne. And thus much of the Nerues of the Hand.

CHAP. XXXI. *Of the Nerues of the foote in the large acception.*

The Nerues of the Legge.

THE nerues which at the beginning of the legge (by leg we vnderſtand here the whole member) doe run into the thighe and the foote, ariſe out of the ſpinall marrow, out of that part, I meane, which conſiſteth of the ſpondels or rackes of the Loines and of the Holy-bone; for they are propagated out of the three lower paires of the loynes; and the four vpper of the holybone,

Their original

and in their very original are mixed like as wee ſaide they were before they entered into the arme, for their coniunction is like the Meiſhing of a net or Plaſhing of a hedge, and ſo they proceede on either ſide in foure nerues. [Tab. 26. char. 57, 60, 66, 71] They are not all of alike thickneſſe, neither is their paſſage the ſame, although their common original be within the cauity of the *Peritonæum* or rim of the belly. The firſt and the third are the ſhorteſt, and therefore they paſſe onely vnto the thigh. The ſecond is longer & thicker then they, and reacheth through the thigh into the legge. The fourth is thicker then al the reſt put together and longer alſo, for it deſcendeth through the thigh and the Legge vnto the ends of the Toes.

The 1 Nerue

The firſt [tab. 26. char. 57] ariſeth of a commixtion of a branch of the third pair of the Loines with the fourth paire [about the 22. & 23 racke-bones] and is terminated aboue the ioynt of the knee. This nerue lying vpon the muſcles of the loines attaineth to the little *Rotator*, and is conſumed into the two extending muſcles of the thigh and a branch of it into the foreſide and outſide of the skinne of the Thigh that lyeth ouer them, but the greater part [char. 59] affoordeth ſurcles to the firſt, ſeauenth, and ninth muſcles of the Legge.

The ſecond.

The ſecond Nerue of the legge [Char. 60] iſſueth ouer againſt the coniunction of the third ſpondell of the Loines with the fourth, [betwixt 23 & 24] and being accompanied with the crurall Veine and Artery paſſeth through the groines into the Thigh, and deſcendeth in a notable branch, which on the inſide [char. 61] is faſtned to the vein *Saphena*, as farre as to the great toe paſſing by the inward Ankle. [char. 62] And this muſt eſpecially be noted because of the Section of the hamand inner Ankle-veines, leaſt if the launcet or Flegme be bent forward you cut the nerue in ſunder: and as the *Saphena* in his deſcens communicateth diuers ſurcles, ſo alſo is this Nerue diuided into many braunches: the chiefe of which is that [char. 63] which we meete withall about the fore and inſide of the knee. The greater portion of this ſecond Nerue [char. 64] beeing accompanied with the *deepe* veine and artery is diſtributed into the forward muſcles of the thigh, eſpeciallie into the fiſt of the thigh and the eight of the legge; yet ſo, as it diſperſeth certayne ſmall ſhoots into the membranes that there tye the veſſels together.

The third.

The third Nerue [char. 66] ariſeth eſpecially where the fourth ſpondell of the loynes is articulated with the ſift, and paſsing ouer the ſeauenth muſcle of the Thigh, it breaketh through the perforation of the ſhare-bone [char. 67] and reacheth ſurcles to the ninth & tenth muſcles of the Thigh, as alſo to the muſcles of the yard which ariſe from the ſhare-bone. It produceth alſo two Nerues that deſcend vnto the middle of the Thigh; one of which is ſprinkled into the skin of the Thigh neere the Groine, [char. 68] the other is conſumed into the ſecond Muſcle of the Legge, and into a part of the fift Muſcle of the Thigh.

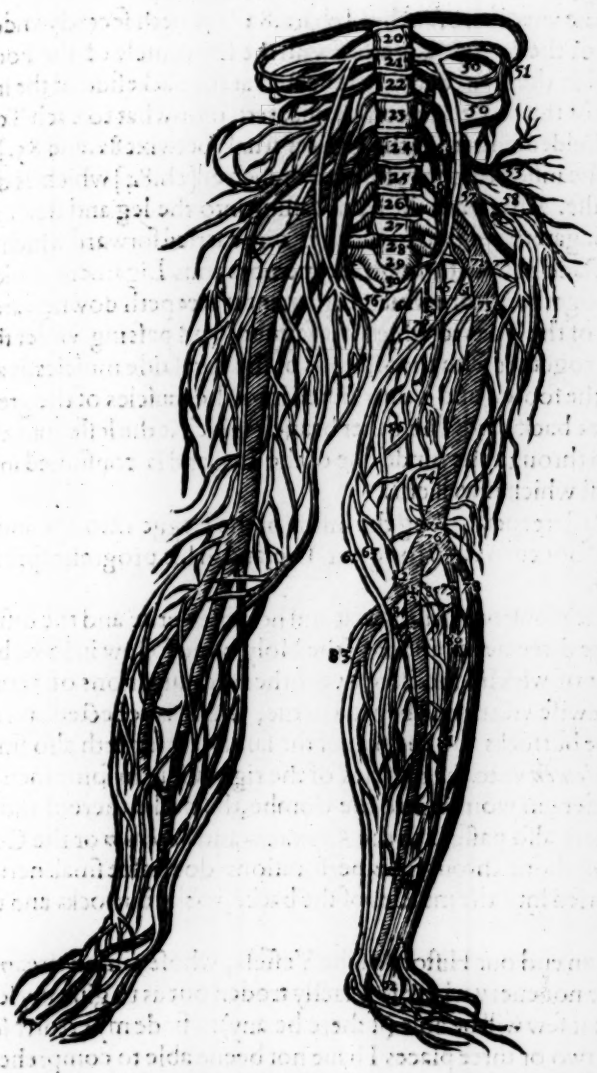
The fourth.

The fourth Nerue [char. 71, 72] is ſixe times as bigge as the thirde, yea to ſay true of all the nerues of the whole body it is the thickeſt, hardeſt, ſtrongeſt and drieſt. This is compounded of the foure vpper paires of the Holy-bone, or of the 25, 26, 27, & 28 coniugations. It goeth on the backſide of the thigh betwixt the *Holy* and the haunch-bones; for where they depart either from other it runneth in a peculiar cauity or *ſinus* of his own, and firſt ſhooteth out ſurcles from a branch lurking on the backeſide [char. 72] vnder the firſt muſcle to the skin which couereth the buttockes and the backeſide of the thigh euen vnto the middeſt thereof. Afterwards, it diſtributeth other branches on either ſide, [char. 73] which for the moſt part are three, vnto the heads of the third fourth and fift muſcles of the legge and the fift of the thigh. Thence forward it is hidden amongſt the Muſcles, and below the middle of the thigh ſendeth a branch [char. 74] vnto the fourth muſcle of the legge, and ſprinkleth propagations into the skin nere the knee. Next in the lower part it diſſeminateth on either ſide one ſurcle [char. 75] at the head of the thighe into the heads of three muſcles of the foote. But the trunke it ſelfe in the backward cauitie of the

His diuiſion.

knee

TABVLA. XXVI. *sheweth the Nerues of the foote in the large acception.*



From 20 to 24 E. Fiue paires issuing out of the spondels or rackbones of the loynes.

50,50. Nerues going vnto the muscles of the *Abdomen*.

5. Branches from these Nerues vnto the *broad* muscle of the arme.

From 25 to 30. Six paire of Nerues of the Holy-bone.

53. A braunch of the paire 25 to the inside of the haunch-bone, and the muscles of the hanch-bone issuing therefrom.

56. The termination or end of the spinal marrow vndiuided.

57. The first Nerue running vnder the Legge or the Thigh.

58. Braunches going from this Nerue vnto the skin.

59. Hence also branches going to the Muscles that occupy the outside of the thigh.

60. The second Nerue of the leg.

61,62. From this Nerue go branches through the inner side of the thigh and the leg vnto the loweſt part of the foote at 62.

63. Surcles from the branch 61 dispersed into the knee.

64 A branch of the 2nerue running vnto the depth of the thigh.

65 Hence also a braunch vnto the muscle of the thigh called *Triceps*.

66 The third nerue of the legge.

67 Propagations from this third nerue vnto the muscles occupying the hole of the share bone.

68 Another braunch vnto the skin on the inside of the thigh.

69 A portion of the third Nerue lying deepe which goeth vnto the muscles.

70, A portion to the second bending muscle of the Leg.

71, The fourth nerue of the leg which is the thickest of the whole body.

72, A propagation hereof vnto the skinne on the backside of the thigh.

73, Another propagation to the heads of the muscles arising from the appendixe of the *Coxa*. 74 Another vnto the fourth muscle of the leg and vnto the skin that is at the ioynt of the knee. 75, Surcles from the fourth nerue vnto the heads of the muscles of the foote. 76, the diuision of the fourth nerue of the Ham into two trunks. 77, The lesser and vtter trunk of this diuision. 78,78 A branch of the said trunk stretched vnder the skin, and caried to the outside of the legge and the Foot. 79, the greatest part heereof betwixt the Legge and the *Brace* 80, A branch distributed vnto the fore-side of the Legge vnder the skin from the branch 79. 81, the greatest part of the braunch 79 going vnto the muscles of the foote. 82, The inner and thicker trunke of the fourth nerue of the legge in the ham. 83. A branch creeping along the inside of the leg and of the foote. 84, A branch of the trunke 82 dispersed into the skin of the Calfe. 85,85, A branch of the trunke 82 creeping through the foreside of the leg vnto the top of the foote. 86, Another braunch creeping behinde amongst the muscles of the foote. 87, The remainder of the trunke 82 conueyed downe by the inner Ankle, and in his lower part affoording to euery Toe two small surcles.

knee or in the ham [char. 76] is diuided into two branches of vnequal thicknes, [char. 77, 82] which are distributed into the whole legge and the foote: for the leg hath no branch from any nerue sauing this alone vnlesse it be a branch of the second paire [ch. 61] which runneth through the inside of the thigh, the leg and the foot; and yet somtimes a branch of this fourth nerue is faine to supply the place of that also.

The vtter of these two vnequall branches and the lesser [char. 77] is presently byfurcated; [char. 78,79] and the greater and vtter part of that byfurcation [ch. 78] which is produced presently about the ham, descendeth along the *Brace* and the outward ankle to the outside of the foote and the little toe, in his way offering surcles to the skin: The other and interiour part of the byfurcation which sometime also is the greater, [char. 79] when The vtter branch.

it

it hath conueyed a branch [char.80] vnto the forepart of the legge, it is hidde neere the Brace among the Muſcles that are called *Peronei* and affoordeth branches vnto them [ch. 81] From thence it ſtealeth along, and is returned toward the Vtter ankle.

The inner branch.

The *Interior* and greater of the vnequall branches [chara.82] runneth ſecretly vnder the muſcles along the backeſide of the Legge, together with the fift muſcle of the Foot & the benders of the Toes ſeated in the Leg, & being reflected at the backeſide of the inner ankle attayneth to the ſoale of the foote and communicateth moſtwhat to each Toe two ſurcles. This branch is ſubdiuided, and from the greater trunk [betwixt 82. and 85.] a little vnder the diuiſion, and in the inſide thereof yſſueth a branch at [ch.84] which is diſtributed into the skin of the Calfe. Afterward the trunk falling into the leg and ſtealing vnder the muſcles thereof propagateth yet two braunches, one carried forward which is greater then the other [char.85.] and paſſeth through the membranous Ligament which faſtneth the Leg and the Brace together; neare which Ligament it creepeth downeward, affording ſurcles to the muſcles of the Toes to which it is faſtned, and paſsing vnder the tranſuerſe or annular Ligament together with the tendons of the foreſaide muſcles, it attayneth vnto the vpper parts of the foote, and is diſtributed into the muſcles of the great Toe and thoſe that leade the Toes backward. The other branch which is the leſſe runneth backward, [char.86.] and paſſeth through the hinde ſide of the Leg and is conſumed into the muſcles of the foote amongſt which it walketh.

His diſtribution.

The leſſer Trunke [char.83.] creepeth along the inſide of the Legge vnto the inner ankle, thence to the inſide of the foot euen vnto the great Toe, and in his progreſſe ſprinkleth diuers ſurcles into the skine.

Columbus after he hath made mention of this great and notable nerue and the diſtribution therof, addeth; After the three perforations of the Holy bone follow in ſome bodies the fourth and the fift, out of which doe iſſue two other Coniugations of nerues which after their egreſſe are likewiſe vnited and beget a nerue, which is reflected and diſtributed into the muſcles of the buttocks and the skin of the ſame. It ſendeth alſo ſmall nerues into the inſide of the *abdomen* vnto the muſcles of the right Gut; in ſome men alſo vnto the muſcles of the bladder; in women into the wombe, the necke thereof and to the muſcles of the bladder: others alſo paſſe into the *Peronæum* and *Scrotum* or the Cod. Out of the backepart of the Holy-bone through his perforations doe yſſue ſmall nerues little and ſhort, which are diſperſed into the muſcles of the backe, to the buttocks and the skin of the backſide.

The concluſion.

And ſo haue we brought to an end our Hiſtory of the Veſſels, whoſe curled ſtreames and wandring paſſages, if I haue not euery where ſo exactly troden out as to giue my ſelfe contentment: yet I preſume that few will be able (if there be any) to finde my error. Notwithſtanding, I confeſſe that in two or three places I haue not beene able to comprehend the meaning of my Authours, if at leaſt they comprehended their owne. Yet I did compare them diligently together; but it is no wonder that in ſuch intricate labyrinths and inextricable Meanders, he that is beſt acquainted with them ſhould ſome time be at loſſe, in which reſpect he that is beſt able to finde the fault, I hope will ſooneſt pardon the offence, I proceede in my taske.

The end of the Eleauenth Booke.

THE TWELFTH BOOKE,

which hath foure parts, {*Of Gristles.* *Of Membranes.* *Of Ligaments.* *Of Fibres.*

The Præface.

OVR Webbe now weares neare the Threds. The glory and beauty of this stately Mansion of the *Soule* we declared in the first book. The outward walles we dismantled in the second. The Cookeroomes and sculleries with all the houses of Office and roomes of repast we suruayed in the third. The Geniall bed and the Nursery we viewed in the fourth and fift. In the sixt we were ledde into the rich Parlor of pleasure, wherein we were entertained by a leuy of Damozels; one *Modest* as Modesty it selfe; another *Shamefast*, another *Coy*, another *Iocond* and merry, another *Sad* and lumpish, and a world of such *Passions* we found inhabiting in the *Little world*, there also we saw the curious clocke of the heart mooued by a perpetuall motion; the Heralds of honor, those nimble and quicke Pursеuants, those agile spirits whose presence giues life, whose pleasance giues cheere & refreshment whether soeuer they are sent. From thence wee ascended in the seauenth Booke by staires of Iuory into the presence Chamber, where the *Soule* maketh her chiefe abode; there we saw the Counsell gathered, the Records opened, and Dispatches made and signed for the good gouernement of the whole family. From thence in the eight Booke we clombe vnto the battlements, and saw the watch of the Senses set to discouer and giue warning of the approches of enemies or friends. In the ninth we obserued the guard appointed to fetch in the prouision from without, to entertaine or giue the repulse, to defend or offend as cause required. In the tenth we discouered the Materials which filled vp the empty distances in the walles, and parted the roomes asunder. In the eleuenth we followed the courses & conuayances, the enteries and Lobyes which leade throughout the whole edifice from chamber to chamber, out of one office into another. Now we are ariued neare the principals of the building, where we may see how they are ioyned, how they are fastened and bound together, how they are couered and defended, how they are interlaced and intertexed. And finally, in the next and last booke wee shall with God to friend come vnto the Principals themselues and to the very foundation & groundworke whereon the whole Frame is raysed.

The first part, Of Gristles.

CHAP. I. *Of the definition, vse, and differences of Gristles.*

BEfore we come vnto the particular Histories of the Gristles, it will bee requisite to speake something in generall which may open their nature, vses, and differences. *A Gristle therefore is a similar part, cold and dry, made out of the thickest part of the seede gathered together by the power of heate, and ordained to secure the variety of motions, and to put by outward violence.* That it is similar is very manifest, because it is altogether like it selfe, the least fragment or particle thereof retaining the nature, temper, and name of the whole. The distinction of a Cartilage.

This Gristle if we will beleeue *Galen* is to be numbred in the list of those parts which are gouerned by themselues and do not gouerne others. It is cold because the heat soone vanisheth away, and dry for that the moysture is vapoured from it, whence also it becommeth hard but not so hard as a bone. The explication of the definition.

The matter of it is the crassament or thickest part of the seede. The efficient is heate, which

which is the immediate organ of the procreating Faculty, to which the *Altering* and the *Forming* vertues are aſsiſtant: yet is not this an extending heate, ſuch as whereby the Membranes are dilated; nor perforating ſuch as boreth the Veines and Arteries, but a more remiſſe degree which gathereth or curdleth the parts together, and is indeede proportionable to cold in outward things, there being nothing actually cold in a liuing body. But as a high degree of heate doth melt the Lead which caketh when it is leſſe hotte though a great heat do remaine yet in it; ſo it is in the body, the greater heate diuideth the parts and the leſſer gathereth, or if we may ſo ſay, congealeth them.

The finall cauſe is expreſſed in the laſt particle of the definition, for although there be diuers vſes of Griſtles as we ſhall ſhewe by and by, yet theſe two are principall. Firſt, to make the ioynts of the bones which are coupled by *Diarthroſis* more gladde or eaſy to mooue, and more ſecure and permanent. Secondly, to defend the parts vnder them from outward impreſſions or iniuries.

The Nature of a Griſtle is much vnlike that of a bone, for ſaith *Ariſtotle*, when the bones are in any creatures wanting, the ſupply is made by Griſtles. Their Tempers alſo are not farre aſunder. Senſe they haue none, becauſe the creature ſhould not be in perpetuall paine, neither indeed haue they any Netues diſperſed through them. Notwithſtanding as we ſhall ſay in the next Booke there are ſome kinde of bones which haue Senſe, The teeth for inſtance; So ſome Griſtles ſeeme to haue Senſe, as thoſe of the Eye-lids, becauſe certaine ſmall Tendrils of Nerues do touch them.

How Griſtles and Bones do differ.

Finally, ſaith *Laurentius*, a bone and a griſtle do differ but *ſecundum magis & minus*. For bones are harder, drier and colder: yet we may ſay further, that all Griſtles are tranſparant, ſmooth and poliſhed, many bones vnequall and ſharpe. Moreouer, a Cartilage or griſtle hath no marrow, nor cauity, nor corners, or celles in it as bones haue, becauſe there was no neede of them, for being not ſo thick or ſolid as a bone their aliment doth eaſily paſſe through their ſubſtance. Wee conclude therefore, that a griſtle is of a middle nature betwixt a Bone and a Ligament, faſter then a Bone and harder then a Ligament.

The vſes of the Griſtles.

The vſes of the Griſtles are diuers and thoſe very admirable and wonderful, The firſt and moſt common vſe is to helpe the motion of the bones which are ioyned with a laxe or looſe articulation, for by the helpe of the Griſtle the motion becommeth more eaſie, more ſecure and more permanent. More eaſie, for being ſmooth and poliſhed, it leuigateth and maketh ſlippery the aſperities or roughneſſe of the bones, and ſo their heads become more glib or prompt in their motion. Whence it is that all moueable ioynts are cruſted ouer with a Griſtle. So alſo are the heads, & the *ſinus* or cups or cauities of bones where they touch one another lined with a ſmooth griſtle. They make the motion more ſecure, becauſe the griſtle encreaſeth the hollowneſſe of the bone that ſo the articulation is not ſo eaſily luxed or put out of ioynt, as we may ſee in the articulation of the arm with the ſhoulder-blade, and in many others. Finally, by the inter-vening of the griſtle the motion is preſerued and made more laſting and dureable, for the extremities or ends of bones being very hard by their mutuall contaction and perpetuall attrition would haue bene worne and fretted, and ſo in time the motion would haue decayed, which inconuenience is auoided becauſe they are compaſſed or lined ouer with a ſoft griſtle.

The firſt

The ſecond vſe of Griſtles is by yeelding to illude or break the occurſation of outward iniuries, as when the bones are beaten or ratled together, or ſome other violence offred, which haply might breake a bone: for being of a middle nature betweene very harde and very ſoft, it cannot be eaſily broken, as that which is hard and friable or brittle, nor eaſily wounded or bruiſed, as that which is ſoft and fleſhy.

The ſecond.

Hence it is that the Extremities of many bones which are expoſed to external offence haue griſtles allowed them, as the Noſe and the Eares. And theſe are the chiefe and primary vſes of griſtles: there are alſo many other by-vſes, as ſome griſtles like bones do ſuſtaine ſome parts, ſome haue muſcles affixed vnto them', and ſome doe ſuſtaine or eſtabliſh the veſſels. Such are the griſtles of the *Larynx* or Throttle and the Rough Artery as alſo thoſe of the Eye-browes, into which as into a pale the beard of haires whereby the eyes are defended are infixed.

By-vſes of the Griſtles.

There is alſo a fourth added, as if they ſhould be defences or muniments to ſafegard the parts ſubiected vnder them. So the griſtles of the breſt-bone and the ribs were made for the defence of the heart and of the lungs, although they make indeed the motion of the

the cheſt more eaſie, becauſe they follow with more readines then bones would, his diſtention and contraction. In like manner the ſword-like cartilage which wee call the breſt blade is thought to haue beene ordained to defend the midriffe and the mouth of the ſtomacke when it is diſtended.

A fift vſe of the Griſtles you may gather out of *Galen* his booke *de oſſibus*, that by their mediation as it were by a glew ſome bones might be conioyned. So the ſhare-bones are vnited by a Griſtle, and that kind of coniunction is called *Synchondroſis*. The fift.

I will adde alſo a ſixt out of *Galens* eleuenth booke *de vſu partium*, to ioyne hard and denſe bones with lax and rare, for it filleth or maketh vp the hollow holes of a rare or lax bone, and leuigateth or maketh ſmooth his rough ſharpenes. The ſixt.

Finally, there are other and thoſe very many peculiar vſes of particular Griſtles. Some belonging to the ſight, ſome to hearing, ſome to ſmelling, ſome to diglutition or ſwallowing, ſome to reſpiration or breathing, ſome to apprehenſion & ſome to progreſsion, as partly hath beene and ſhall further be declared in the Hiſtory. Many peculiar vſes.

For the differences of griſtles they are to be taken from their ſubſtance, magnitude, figure, ſite, vſe, and connexion. From the ſubſtance or rather from thoſe things which follow the ſubſtance, that is, hardnes and ſoftnes; ſome griſtles are hard which at length become bony as thoſe that forme the *Larinx*; others are in a meane which doe neuer degenerate into the nature of a bone, as that which we call the *Epiglottis* or *Ouer-tongue*; others are ſoft which tye the ioynts together and carry in them the nature of a ligament, & ſuch are called χονδροδεσμοι. From the magnitude, ſome are great and others are ſmall. From the figure, which is very diuers Griſtles haue diuers names, as *Enſiculata*, *Annularis*, *Scutiformis*, *Aritenoides*, *The blade Griſtle*, *the ring Griſtle*, *the ſhield Griſtle*, *the ewre Griſtle*. From the ſite, ſome are called vpper ſome lower, ſome fore ſome after, ſome internall ſome externall Griſtles. From the vſe wee may alſo gather differences and varieties of Griſtles. Some are made for motion, ſome to auoyde outward iniury, ſome for defence and ſome onely for ſupportation. The differences which are taken from Connexion are more neceſſary and therefore a little the more to be ſtood vpon. A griſtle therefore either groweth to a bone or maketh a part by it ſelfe. That which groweth to a bone, eyther tyeth two bones together, or elſe is onely faſtened to a bone. That which tyeth two bones together, eyther doth it by the interpoſition of common ligaments, as it is in the ende of bones that are connected by *Diarthroſis*, or immediately as in the ſhare-bones & the breſt-bone. That which is faſtened to a bone appeareth in the griſtle of the Noſe, in the breaſt-blade and that which groweth to the *Coccyx* or the Rump. The griſtle which maketh a part by it ſelfe is by ſome called *Solitaria*, ſuch is the griſtle in the extremity of the Eye-liddes, ſuch are the griſtles of the *Larinx* or Throttle, of the rough artery, of the outward eares and of the *Epiglottis* or Ouer-tongue. The differences of griſtles.

But for more perſpicuity we will referre the whole hiſtory of the griſtles vnto three heads. Thoſe of the head, thoſe of the trunke, and the griſtles of the ioynts: the griſtles of the head are, of the Noſe, of the Eares, of the Eye-lids and of the lower Iaw. The trunk is diuided into the Spine and the Cheſt. The parts of the ſpine are the necke, the backe, the loynes, and the holy-bone. The griſtles of the necke are eyther behind or before. Behind, thoſe that tye the ſpondels together; before, the Throttle, the Rough artery, and the Ouer-tongue. The griſtles of the cheſt are thoſe in the extremities of the ribs, and thoſe of the breaſt-bone. The griſtles of the ioynts are ſome of bones receiuing, ſome of bones receiued, and of each of theſe ſome belong to the Hand and others to the Foote. A diuiſion of griſtles.

CHAP. II. *Of the Griſtles of the Face.*

OF the Eye-lids we haue ſpoken before in the third chapter of the eight book which we will not now repeate, onely heere remember that a great part of them are cartilaginious or griſtly, by which the opening and ſhutting of the eye is made equall, by which the violence of outward iniuries is better reſiſted, and in which the ſmall hayres that keep duſt and flyes from the eyes are infixed and ſuſtained, which otherwiſe would haue fallen if the lid had beene onely made of fleſh and membranes. The griſtles of the eie-lids

Againe, if they had beene bony, they would not haue beene ſo eaſily moued, and beſide, their hardnes would haue offended the coates within the eyes which are of exquiſite ſenſe. But this griſtle is very thinne that it might be a little tranſparant to caſt a little ſha-

dow

dow of the externall light vppon the Eye. There are two of them, one vpper and another lower; the vpper is greater in a man, and in those creatures whose lower eye-lids are immoueable, or their motion, if it be any, very little and obscure, whereas in Birds the gristle of the lower lid is the greater. They are called ταρσοὶ, because the row or beard of haires, which is set in so many perforatiõs made in the gristle, are not vnlike a rank of rowers in a Galley. There is also another gristle in the greater angle of the eye, which hath the figure and vse of a Pulley described elegantly at first by *Falopius*. This Pulley hath a Canale or open perforation through which the tendon of the muscle that mooueth the eie round is conuayed, but of it we haue spoken before. In the ioynt of the lower iaw there is a slippery and mooueable gristle which hindereth least the bones of the temples and the iaw should by their mutuall attrition be worne, or when they are wearied with too much labour giue ouer their motion.

Of the outward eares. The outward eares called in latine *Auriculæ*, are also gristly, for if they had beene bony they might easily haue beene broken, and beside would haue beene an impediment in our sleepe.

Againe, if they had beene fast and fleshy they would not haue retained their arched figure, and so the ayer should haue beene shut out, or if it had beene admitted, a fleshy substance could not haue repelled the sound. These gristles are aboue, thicker and harder, below, thinner and softer till you come to the dap which is of a mixed nature between flesh and gristle.

Of the nose are fiue. The gristles of the Nose are fiue, the three anterior are fastened to the circumferences of the bones, and two make the *Wings*.

Of these the two vpper are the broadest and adhere to the bones of the nose [Tab. 12. lib. 8. fig. 8. from *f* to *c*] where they are broad and rough. From them they hang, and together with them doe forme the anterior cauity of the nosthrils and their lower part. Descending downeward they run out being fastened together vnto the tippe or toppe of the Nose, and the lower they goe the softer they are, in the very extremity degenerating as it were into a gristly ligament. The third gristle which is in the middest betwixt these two is called *Septum cartilagineum*, the gristlie partition, which groweth to the bony partition, for it depending forward groweth to the foresaide gristles throughout their length on the inside. This is the gristle which maketh the Nose to rise in the face, and distinguisheth the two nosthrils, where also the bony partition aboue the region of the Pallate separateth the perforation of the nosthrils from the Nose vnto the Chops. To these three gristles other two are annexed which make the wings of the Nose called *ala* or *pinna*, because like wings they shut and open the nosthrils, and they are tyed with membranous ligaments to the former gristles on their inside. Each of these gristles is orbicular and so make the holes of the nosthrils round, and indeed they approch neare vnto the nature of a ligament.

Their vse. Moreouer they haue voluntary motion being drawne vpward and downward, inward and outward by proper and peculiar muscles, and in great inspirations they are a little eleuated, but in expirations do settle againe. They are seated in the lower part of the Nose, for the vpper is bony to be a foundation vnto the rest: but it behooued that the lower part of the Nose should be gristly; partly that the cauities might remaine alwayes open for the better attraction of the ayer into the Lungs and into the braine; partly that being soft we might close our Noses against any euill sauours, partly also the better to euacuate the excrements of the braine through the nosthrils; and finally that they might yeelde to outward violence to which they are most of all exposed. This part of the Nose if by any casualty it shal happen to be cut off may be elegantly restored *by a Traduction of skinne out of the arme*, as we shal (God willing) at large discourse and exhibit the figures of that kind of deligation in our worke of Surgery. And so much concerning the Gristles of the Face.

CHAP. III. *Of the Epiglottis, the Gristles of the Larinx and of the Weazon.*

Epiglottis. OF the *Epiglottis*, the gristles of the Throttle, and the Weazon we haue spoken before in the 18 chapter of the 6 booke, and in the 34, and 36 chapters of the eight booke; wherefore heere it shall be sufficient to touch vpon the and so to passe vnto the rest that follow. You must therefore remember that the *Epiglottis* is nothing else but a gristle that lyeth vppon the cleft or slit

slit of the Larinx made of the two processes of the Ewre gristle. The forme of it is compared to an Ivy leafe, whose basis is broade but the cone not very sharpe. The basis is in the vpper and inner side of the shield gristle, the cone vergeth toward the Pallate. If this gristle had been bony, it would not so easily haue beene depressed in diglutition, nor readily againe lifted it selfe vp for the inspiration of ayer. If it had beene fleshy or membranous it would indeed haue easily fallen but not so readily risen againe. The vse of it is double. The first to couer the Larinx, that in swallowing the meate and the drinke might not passe into the Lungs. The second vse is to breake the ayer that is driuen out of the Lungs and to Modulate the voyce.

This gristle saith *Laurentius* standeth alwayes yawning open, as well when wee draw in our breath as when we breathe it forth. Neyther is it at any time depressed of it owne accord but onely by the weight of the meate and drinke which we swallow, neyther at that time is it so exquisitely closed vp but that a portion of the drinke sipeth by into the Artery.

The gristles of the Larynx

As the *Epiglottis* is the couer of the *Larinx*, so is the *Larinx* the head or couer of the Rough artery. The whole body of it is almost all gristly, for being the Organ of Breathing it was necessary it should euer be open whether we had neede to take in fresh ayer or to breath out old.

Againe it is the Organ of the voyce which is nothing else but a percussion of the ayre. Now the ayer is not broken but at a solid, hard, and light body. It consisteth of three gristles or rather of foure, which are so fastened together that by them it may easily be dilated and constringed, shut and opened. The first is called *Thyroides* the shield-gristle, because it is like a square shield such as is carried before Tilters in their triumphs; and this is sometime double, especially in women, in whom likewise it bunccheth not out so far forward as it doth in men. The second is called *Cricoides* the Ring-gristle, for it is wholy circular and keepeth the pipe open. It preuenteth also the compression of the rest of the semicircular gristles in the motions of the Larinx. The third is called *Arytænoeides*, or the Ewre-gristle, because it is like an Ewre with which we vse to powre water vppon mens hands, or rather it hath this denomination from the similitude it hath with an oyle cruise.

The first Anatomists accounted this gristle single, but those that haue come since haue found it to be double, and that the parts therof are connected or knit together with membranes or with ligaments. And indeede these parts thus ioyned do make the *glottis* or cleft of the Throttle. The opening or closing of these parts make the voyce base or treble, but the *Epiglottis* striketh a great stroke in it as it shutteth his cleft more or lesse. *Columbus* saith that these gristles do somtimes turne to bee bones. And thus much of the Larinx; now we proceede to the rough Artery.

The Weazon

The Weazon becausse it is a vocall Organ or wind instrument, fistulated or made hollow to lead ayer vnto the Lungs and to returne out of the fumid vapours the recrements of the spirits, it was for the greatest part made of gristles, and thence it is called τραχεῖα, *Arteria aspera* becausse it is asperated or made rough and vnequal with gristlie rings. Now a gristle is the fittest instrument of the voyce becausse it is of a middle nature betwixt harde and soft, for soft things becausse of their weakenesse doe strike the ayer more remisly, and hard things doe easily ouerturne it. Why Gristly.

These gristles are like rings, not round rings, for on the backpart where they touch the gullet they end into membranes, so that they are but semicircular like the letter C, from whence also they are called σιγμοειδεῖς. These gristles saith *Laurentius* do not onely run as far as the Iugulum as some haue dreampt, but throughout the whole course of the artery they are in all his branches that passe into the whole flesh of the Lungs.

Why the rings are not round.

The reason why these gristles were not made perfectly circular, I thinke was, as well that the Gullet should not be hurt with the hardnesse of the artery, as also that we might swallow the more freely, for oftentimes wee swallow hard and vnbroken bittes which would out of doubt offend vs vnlesse the artery did yeeld vnto the Gullet.

It may be obiected that the body of the Larinx or Throttle is wholy gristly, and yet it hindereth not the Gullet.

But there is a great difference betwixt these, for in deglutition or swallowing the Gullet is drawne downeward but the *Larinx* runneth vpward, so that the situation of those

parts is changed, and the beginning of the Gullet approcheth vnto the rough artery, but the throttle aſcendeth as high as to the chops.

Moreouer theſe griſtles are ſemicircular onely in the vpper part as low as the *Iugulum*, but when they are paſt the *Oeſophagus* and come vnto the Lungs, they grow round becauſe it was neceſſary that the artery in the Lungs ſhould be kept open for the freer traction and expulſion of the ayer. He that deſireth further ſatisfaction concerning the nature of theſe griſtles, let him repaire to the 18 chapter of the 6 booke.

CHAP. IIII. *Of the Griſtles in the Trunke or Bulke of the Body.*

The griſtles of the Spine.

THE Griſtles that are in the bulke of the body are eyther in the rack-bones of the Spine or in the Cheſt. In the ſpine there are many griſtles to eſtabliſh the articulation of the ſpondels, and to make their motion more facile and eaſie. All the *vertebræ* of the necke haue griſtles aboue and below, excepting the firſt, ſo is it likewiſe in the backe and in the loynes. But thoſe of the holy-bone are harder and drier then the reſt becauſe the whole bone is immoueable.

The extremity alſo of the holy-bone is griſtly, and is called *Coccyx* or the Rump. It carrieth the figure of a Cornet or paper wherein Grocers vſe to put vp their Spices, ſauing that the cone or ſharpe end is ſomewhat beaked or crooked. This eſtabliſheth the right gut, as alſo the neck of the womb and the bladder, and when women are in trauel it is bent backward not without very great paine.

Of the griſtles of the Cheſt.

For the cheſt it behooued well that ſome part of it ſhould bee griſtly that it might more eaſily follow our inſpiration and expiration. Firſt therefore there are two griſtles which ioyne the clauicles to the breſt-bone. Then the *Sternon* or breſt-bone hath a griſtle in the vpper and another in the lower part. In the vpper part betwixt the firſt and the ſecond bones which ſerueth inſtead of a ligament, but below appeareth that notable griſtle which they call *Xiphoides* or the breſt-blade. The forme of this griſtle is very diuers, for it is not alwayes acuminated or pointed; but ſometimes broad in the end, and ſometimes tyned or diuided into two forkes and thereupon ſome haue called it *Furcella* the little *Forke*. Oftentimes ſaith *Laurentius* we haue ſeene it round like the *Epiglottis*. Sometime the parts are vnequall, and the leſſer lyeth ouer the greater like the leafe of the herbe which we call Horſe-tongue, about the middle of it it is perforated with a ſmal hole which few haue obſerued, made to tranſmit a nerue and a veyne.

the breſtblade

The vſe of it.

The vſe of this griſtle is the ſame with other griſtles which hang at the ends of bones to witte, by yeelding to breake the violence of outward iniuries, and to defende the parts ſubiected thereto. Some thinke it was made as a defence for the midriffe which in that place is neruous; ſome to ſafegard the mouth of the ſtomacke, hence ſay they often comes a *Nauſea* or loathing of the meate when this griſtle is bent inward and preſſeth the mouth of the ſtomacke. Some of the Neotericks or new VVriters do deride this latter vſe, becauſe ſay they there is a great diſtance betwixt this griſtle and the mouth of the ſtomacke which is applyed to or leaneth vppon the backe, but *Laurentius* ſaith it is falſe that there is any ſuch diſtance in liuing bodies, for firſt they that vomit much when they are about to caſt, do find a paine at this griſtle.

Againe, *Hippocrates* in the third ſection of his booke *de Articulis* hath remembred ſuch a diſtention of the ſtomacke to the foreparts where he ſaith *That the repletion of the belly* (he meaneth the ſtomacke) *is a direction for broken ribs.*

Moreouer in *Coacis* he calleth the mouth of the ſtomacke *Sternum*, where he ſpeaketh *of the bitternes and gnawing of the Sternum*, that is, of the mouth of the ſtomack; but aboue all that is abſurd with old wiues fable, who ſay that this griſtle ſomtimes fals away and may be replaced againe by muttering a peece of the mattens ouer it, and by attrectation or groping vppon it.

Two griſtles in each rib.

Finally, euery rib hath two griſtles, one on the backſide where it is articulated to the ſpondell: another on the foreſide by which it is ioyned to the breſt-bone. But the forward are greater and thicker then thoſe that are backward, becauſe the fore part of the cheſt is diſtended and contracted. The griſtles alſo of the baſtard ribs are longer then thoſe of the true ribs. And ſo much for the griſtles of the Trunke.

CHAP.

CHAP. V. *Of the Griſtles of the Ioynts.*

THere is almoſt no Ioint in the whole body of Man, but for his more ſecure and facile motion it is cruſted ouer with a Griſtle, as partly wee haue ſhewed before in particular. Moreouer in the cauity or hollowneſſe of the Shoulder-blade Nature placed a Griſtle to increaſe the *ſinus* or boſome of the bone, leaſt in violent motions the ioynt ſhould bee eaſily luxed or put out.

In the lower part of the Cubit which hath an acute or ſharpe proceſſe there appeareth a griſtle which filleth vp the empty diſtance. It hindereth the Hand when it is led to the ſide frō offending againſt that acute proceſſe. Betwixt the Shate-bones there is a thick & hard griſtle ſo vniting them together that it is not credible they ſhold be ſeuered in the time of trauell, as we haue ſhewed before in the 33. Queſtion of our firſt booke. In the cauity of the hanch-bone there is another griſtle which increaſeth the compaſſe of the boſome or cauity therein. Of the cubit. Of the hanches.

Finally, in the lower heads of the thighes we finde two ſemicirculer griſtles which inlarge the lippes of the cauities. In a word almoſt euery articulation is cuſted ouer with a griſtle to make the motion more eaſie, more ſecure and more permanent: and ſo much concerning Griſtles. Now we proceede vnto the Ligaments.

The ſecond part of Ligaments.

CHAP. VI. *Of the Nature, Vſe and differences of Ligaments.*

AS the lubricity of Griſtles makes the motion of the Bones more nimble and quicke: ſo the Ligaments doe ſecure both motion & articulation: but there is a double acception of a Ligament, the one large, the other preſſe and more reſtrained. In the firſt Senſe we call any thing a Ligament which tyeth one part to another. So *Hippocrates* calleth the skin and the fleſh *colligations*, the ancients alſo called all manner of veſſelles Veines, Arteries and Sinnewes, *Common Ligaments*. In the preſſe and ſtrict ſignification wee call that a Ligament which is a hard and firme body, yet laxe and flexible and without ſenſe, which incompaſſeth, tyeth downe and contayneth the ioynts. A double acception of a ligament.

This kinde of Ligament properly ſo called, the Grecians call συνδεσμος, the Latins *copula, vinculum & Ligamentum*, wee may call it a *Tie*, but becauſe the worde Ligament is growne into common vſe, we will if you pleaſe retayne it for the moſt part. *Laurentius* giueth this definition of a Ligament. It is a ſimilar cold and dry part, of a middle nature betwixt a Nerue and a Griſtle (betwixt a Membrane and a Griſtle ſayth *Bauhine*) ingendred by the power of heat out of the ſlimy part of the Seede, and being of great vſe in colligation, contayning, inueſting and forming of Muſcles. Concerning the Temper of a Ligament (which is the forme of the ſimilar part) all men do agree that it is cold and dry, albeit ſome peculiar ligaments of ioyntes are lined ouer with a mucous and ſlimy humour, but concerning thoſe things which accompany, follow and happen to the temper many haue made ſcruple: hardneſſe and ſoftneſſe followe the temper, ſenſe and motion happen vnto it. We reſolue that Ligaments are of a middle Nature betwixt Griſtles and Membranes harder then Membranes; leaſt in vehement motions they ſhould bee broken, and ſofter then Griſtles, that they might more eaſily follow and obey the Muſcles which moue the bones. For the moſt part they are all inſenſible, as well becauſe they receiue no Nerues into them, as alſo leaſt being perpetually moued they ſhould breed perpetuall payne. The definition of a ligament.

It may be obiected that *Galen* in his 3. booke *de facult. natural.* ſayth that Ligaments conſiſt of ſenſible fibres, but we muſt know that by *ſenſible* in that place *Galen* vnderſtandeth not that which hath Senſe, but that which is liable to Senſe, not that which is ſenſatiue but that which is ſenſible. For Ligaments borrow nothing from the brayne, and therefore haue no ſenſe, neither can they mooue themſelues, notwithſtanding as among the bones the Teeth haue ſenſe, among the griſtles thoſe that make the Eye-liddes, ſo amongſt the Ligaments there are ſome which haue the ſenſe of touching, as the two ligaments that make the yarde, and the reyne or bridle of the Tongue

The matter of ligaments,

The matter of Ligaments is the slimy part of the seed extended or lengthned by heat, whence it is that they can bee contracted and againe relaxed. Their Aliment I doe not take to be (sayth *Laurentius*) as some would, marrow, but bloud conuayed vnto them by *Capillary* veines, which are so little that they cannot be perceiued.

Their vses.

The vses of Ligaments are diuers, the first and most common is to firme and assure the articulations, especially those that are more laxe of the bones and the gristles, and to hinder luxation, for it was to be feared that when the bones are separated in violent motions they should be also distracted, vnlesse the wisedome of Nature had prouided to tye their extremities together with strong and straite bonds. These Ligaments which performe this vse are either common which compasse the ioynt round about, or priuate. The common are thin and membranous, the proper are thicker and most what round.

The second vse is to bind and fasten the bones where they are not articulated, for there are thinne and fine Ligaments which tye the cubite to the *Radius* and the Legge to the *Brace* where they gape asunder, as also the spines of the spondels.

The third vse is that which *Galen* remembreth, who sayeth they serue for an outward garment to defend the tendons. So the tendons which bend and extend the Fingers & the Toes are throughout their whole length couered with Ligaments & with membranes.

Adde hereto the fourth to contayne the Tendons in their owne places, to establish them and safely to transmit them from one place to another. Such are the Transuerse Ligaments of the wrest, round like a ring and therefore called *Annularia*.

Fiftly, they are interposed like a pillow betwixt the bones and the Tendons, that the hardnes of the bones should not offend the tender and sensible tendons.

Sixtly to discriminate or separate the right muscles from the left, the fore muscles from the hinder, and other parts one from another as we may see in the Ell and the *Wand*, in the *Leg* and the *Brace*.

Seauently to encrease and augment as do the gristles the *Cups* of the bones.

Eightly, to suspend the bowels that they should not fall with their great waight. Such are the Ligaments of the Liuer, the Bladder and of the Wombe.

Finally, they concurre vnto the structure of a muscle, for of the fibres of a nerue and a ligament mixed together is a tendon made.

The differences of ligaments.

The differences of Ligaments are to be taken from their substance, magnitude, figure, site, originall, insertion, vse, and from their principall parts. From the substance some are soft, some hard, some membranous, that is, like vnto membranes, because they be broade. Some are neruous, that is, round like nerues, some are gristly. From the magnitude some are little some are great, some are broade and some are narrowe. From the figure some are broade some are round, some are continuall some are perforated, some are transuerse and annular and some are long and direct. From their situation they are supernall infernall, right left, fore and backe Ligaments.

From their originall and insertion their diuision is very elegant, some arise from bones, some from gristles, & some from membranes. Those which arise from bones are inserted either into a bone or into a gristle, or into the heads of muscles, or into some other part. Of those which arise from a bone and are inserted into a bone, some do firme the ioynts, others tie the two bones together without a ioynt, others defend and inuest the tendons. Those which arise from a bone and are inserted into a gristle doe appeare in the knee, one from the internall roote of the inner *Cup*, the other placed vnder it. Those that are inserted into the heades of muscles are very diuers, some grow out of bones and runne into other parts, as that double Ligament which maketh the greatest part of the yarde, and ariseth out of the share-bones. Those Ligaments that arise out of gristles are some of them inserted into gristles; such are they that tye together the gristles of the *Larynx*; they that are in the end of the Rump and those that tye together the halfe circles of the Rough artery; others are inserted into the heads of muscles, as those that runne into the proper muscles of the *Larynx*. Those ligaments that arise from membranes are but few.

From the vse you may gather diuers differences of Ligaments according to the vses before named.

Finally, from the principal or more notable parts of the body we may very fitly deuide Ligaments into those of the Head, those of the Chest and Back, and those of the Ioynts, according to which diuision we will now prosecute their particular History.

CHAP

CHAP. VII. *Of the Ligaments of the Head.*

THE Ligaments of the Head doe some of them belong to the whole Head, some to particular parts thereof: the whole Head is mooued about the first and the second *vertebra* or spondell of the necke, wherefore it was needfull that it shold be fastned with strong ligaments, otherwise a notable part had bin in danger of luxation. Of these Ligaments *Bauhine* reckoneth 4, *Laurentius* but three, which notwithstanding (sayeth hee) may bee deuided into more particles. The ligaments of the head.

The first is a very great and broade Ligament which tyeth the first Racke-bone vnto the Head and compasseth the whole ioynt round about. It hath two portions, one like a thicke membrane and runneth to the inside of the first spondel, the other part compasseth about the outside of the ioynt. It ariseth out of the *Basis* of the *occiput* or Nowle of the head, which is therfore exasperated, and in young children is scotched or cleft manifold: hence it is that the first and second *vertebræ* may sooner be broken then luxated. The first.

The second Ligament fastneth the processe of the second Rackbone called the *Tooth* to the head, and it consisteth of three parts. Two arising from the outside of the *Tooth* are inserted into the inside of the circumference of the hole which is in the nowle-bone. The third is round like a nerue and ariseth from the foreside of the *Tooth*, and is infixed likewise into the hole of the Nowle to which it adheareth very strongly. Second.

The third Ligament is very like a nerue and made with wonderful art, and compasseth the cauity of the first Racke-bone which was made to receiue the Tooth of the second, & constringeth the sayde tooth, so firming it that it cannot incline to either side; it safeguardeth also the spinall marrow least it should offend against the bare bone. Third.

The fourth Ligament ioyneth the second Racke-bone to the first. It is membranous and of the same nature and vse with the other ligaments of the ioyntes; and these are the common ligaments of the head. There are also other proper ligaments in the head which belong to particular parts: as the ligament of the gristle of the Eare: a strong ligament, for it fastneth the roote of the gristle to the stony-bone, and ariseth with diuers propagations from the *Pericranium*, where it tendeth toward the *Mammillary* processe. These propagations when they come vnto the eare do grow together into one ligamēt & it is inserted into the vpper & gibbous part of the eare to hold the gristle pricked vp & suspended. Fourth. Of the ligament of the eare.

There is a ligament also in the Eye called by *Falopius*, *Ligamentum Ciliare*, not because it is of the nature of a ligament, but because the grapy coat is thereby fastned to the verge or circumference of the membrane of the Christalline, but wee haue spoken of it sufficiently before in the end of the 7. Chapter of the 8. Booke. Of the eie.

The Ligaments of the vpper Iaw betweene the *sutures* and the *harmonies* are thin and membranous, made for the original of the muscles, for from them the tendons of the muscles of the Face and of the neighbour partes take their originall. The articulation also, sayth *Galen* in the 20. Chapter of his first booke *de vsu partium*, of the lower Iaw with the Temple bones hath strong ligaments, which *Bauhine* out of *Platerus* calleth a common membranous ligament incircling the whole ioynt. Of the Iaw.

The Ligament of the Tongue *Galen* discourseth of in the 10. chapter of his 11. booke *de vsu partium*. It is strong, membranous and broad, but of it wee haue spoken before in the 32. chapter of the 8. booke. Of the ligaments of the bone *Hyois* we shall speake in the booke of Bones. Of the ligaments in the Heart, in the Rough Artery and the cutany ligament of the wombe we haue spoken before in their proper places, which wee will not now stand to repeat, but proceed on vnto the ligaments of the Spine and the Chest. Of other parts.

CHAP. VIII. *Of the Ligaments of the Spine and the Chest.*

THE motions of the Spine are very diuers, and therefore the Rack-bones stood need to be fastned together with ligaments. In these Rack-bones we may obserue their bodies and their processes. In like manner there are two sortes of ligaments, one kinde fastneth the bodies of the spondelles, another their processes, and these saith *Bauhine* are of two sorts, the one is strong and mucous, which compasseth the bones and fastneth the whole length of the Spine; in violent motions downeward and great burthens securing it from danger. Liga. of the Spine.

The other sort is gristly, and *Galen* indeed in his Booke *de ossibus* calleth them Gristles, which kinde goeth betwixt the bodies of the spondels and fastneth them strongly together.

It is fibrous and mucous, thicke without, but toward the middest attenuated, and carrieth the very forme of the spondell, answerable to it in breadth and length, and determineth into the gristle which is betwixt the spondels.

The ioyntes of the processes are also fastned with common membranous ligaments, the ascendents with the descendents. Furthermore there is another priuate or particular Ligament and yellowish, arising out of the inside of the hole of the Rack-bone at the roote of the backward processe betwixt two ascending or descending processes, and is againe inserted into the same place of the subsequent spondell.

In the necke of a Dogge wee meete with a Ligament which is rare indeede but strong and yellow, and cannot be parted into fibres. It groweth out of the very top of the spine of the seuenth Racke of the necke, and ascending vpward free and at liberty is fastned into the top of the second spine of the necke. In sheep it groweth to the Nowle-bone. In beastes of burthen it is very thicke for more strength, and of all the Ligaments of the body is refused for meat; yet sayth *Vesalius* some commend it to be eaten to make the haire grow long. It may be (sayth he) because it is easily dissolued as it were into yellow haire. In some creatures throughout the length of the backe runneth a Ligament on each side betweene the muscles that moue the backe, which sayeth *Vesalius*, *Galen* also attributes to men in his bookes *de vsu partium*.

Of the chest. The Chest also hath his Ligaments for all the ioynts thereof are ioyned with common membranous Ligaments compassing them about. So the ribbes are fastned to the spondels with strong and almost gristly Ligaments, especially in the first and second rib because of the burthen which they were to beare; likewise in the twelfth, because it is not sustayned with a transuerse processe. The same ribs are ioyned by the mediation of Ligaments to the gristles of the breast-bone. The bone also of the Breast it selfe is fastned to the clauicles by the interposition of a proper Ligament.

CHAP. IX. *Of the Ligaments of the Shoulder-blade, the Arme, the Cubit, and the Wand.*

THE head of the Arme being round that the whole Hand might moue speedily euery way, and the cauity or *Cuppe* of the Blade being but shallow; (as whose browes are narrow) least in the diuers motions the Arme should bee luxed, Nature partly by two recurued processes of the blade, partly by Ligaments which defend the ioynt, hath prouided for so desperate an inconuenience.

Fiue ligaments of the arme. These Ligaments are fiue. The first is *Broade*, so *Galen* calleth it, and membranous like the Ligaments of other ioyntes. It taketh his originall circularly out of the verges or browes of the necke of the Blade, incircleth the whole ioynt about, and is infastned on the inside of the beginning of the head of the Arme, and is implanted to the outside of the head and into both their necks.

The second is perfectly round, as also is the third, and groweth from the top of the *interior* processe of the Blade, and compasseth about the inside of the vtter heade of the Arme whereto it groweth very strongly.

The third is thicker and greater then the former and ariseth out of the vpper part of the necke of the Blade, and climing ouer the head of the arme, is inserted into the outside thereof, where at his cauity the ouside buncheth out somewhat, so that these two Ligaments together make as it were one transuerse Ligament.

The fourth is broade also and yssueth out of the same place with the third. His originall is large, and runneth obliquely till it be infixed into the backeside of the vtter head of the Arme where it compasseth the backepart of the ioynt as did the first.

The fift yssueth from the *interior* processe of the blade and runneth vpward to the top of the shoulder.

The vse of these Ligaments is; of the first the same with the Ligaments of other ioints; of the three next to keepe the arme that it fall not downeward or outward out of his socket. Of the fift to keepe the arme from luxing forward, in which seruice it is holpen by the outward head of the double headed muscle.

For

For the Cubit, although throughout his length all the muſcles are compaſſed with a ſtrong membrane which faſteneth them together, holdeth them in their places, and like a tranſuerſe ligament as it were bridleth them vp growing to them very ſtrongly and cloſely as the proper membrane of a muſcle doth; yet there are other ligaments which ioyne the bones together. VVherefore the cubit, which is compounded of the El and the VVand, hath ligaments wherby it is faſtened to the arme, to the wreſt, & alſo the two bones of the cubit together. To the arme it is faſtened with common ligaments, ſtrong but membranous, which tye the Ell to the arme and the wand to the vtter protuberation of the arme. But to the wreſt it is articulated with a membranous ligament common to other ioynts, and beſide with two proper round ligaments, one faſtened to the Ell which runneth from the proceſſe called Styloides vnto the fourth bone of the wreſt and is more griſtly then the reſt; the ſecond faſteneth the wand to the wreſt, for it iſſueth out of the top or pitch of the wand and runneth into the wreſt. The ligament of the Cubit.

Againe, theſe two bones of the Ell and the VVand are vnited by a common ligament aboue and below, as alſo by a peculiar which is membranous & ſtrong running throughout the whole length of both bones, for his ſituation is in the diſtance betwixt them, ariſing from an acute line of the Ell, and inſerted into a line of the VVand. It hath alſo oblique fibres which creepe downeward obliquely from the VVand vnto the Ell.

The vſe of this ligament is to conioyne and faſten theſe bones together, to diſtinguiſh the exterior muſcles from the interior, as alſo to affoord an originall to ſome muſcles, or at leaſt to adde ſtrength to their originals. Their vſe.

CHAP. X. *Of the Ligaments of the Wreſt, After-wreſt, and the fingers.*

THE bones of the VVreſt haue common Ligaments with which they are in a manner inueſted, for ſomtimes and in ſome places they get betweene the bones and become griſtly. This common ligament iſſueth from the lower appendix of the Ell and the VVand. It is very ſtrong and ſo faſteneth the bones that they become fit for their proper motions which are indeede but obſcure, for they are implanted into the appendix of the bone of the After-wreſt. the ligaments of the wreſt.

The bones alſo of the After-wreſt are faſtened together by common ligaments, which doe not onely compaſſe the bones orbicularly, but alſo, neare their extremities in the middle where the bones doe meet one with another, they inſinuate themſelues, becomming of the nature of a griſtle, ſo as they paſſe againe outward and ioyne the bones of the After-wreſt to the wreſt. Of the After-wreſt.

Finally, the knots or knuckles of the fingers are faſtened together with common Ligaments, beſides which there are yet in the hand other ligaments which do not ſerue to articulate or ioyne the bones, but do onely incompaſſe and containe the tendons that go vnto the fingers, leaſt when they are moued they ſhould ſlippe out of their places. This kind of ligament is double, one at the inſide of the wreſt tranſuerſe and broade, ſtronger alſo then the reſt of this kind. It compaſſeth the wreſt like a bracelet on the inſide eſpecially, and holdeth together al the tendons that fall downe to the hand: from it alſo ſomtimes proceedeth the tendon of the muſcle called *Palmaris*. Of the fingers

The other ligament is on the outſide where the wreſt is articulated to the Cubit. It taketh his originall from the two forenamed appendices or out-ſhootes, and is ſpread ouer the whole breadth of the Cubit.

At the firſt ſight it ſeemeth to bee but one, but when it is diſſected it appeareth to bee ſixe tranſuerſe ligaments, which like Rings are ſhot ouer the tendons of the muſcles that extend the fingers, whereby thoſe tendons are contayned or faſtened together. 6 tranſuerſe.

The firſt proceedeth out of the Ell into the VVand and runneth vnto the Sinus or cauity which is common to them both and is peculiar to the ſixt muſcle that extendeth the fingers.

The ſecond belongeth properly to the Ell and to the firſt extending muſcle of the wreſt.

The third is proper to the VVand and to the extending muſcles of the forefinger, the middle finger and the Rin-finger.

The fourth is an exceding narrow Ring belonging to the ſlender tendon of the muſcle that leadeth the fore and middle fingers from the thumbe.

The fift maketh a way for the ſecond extender of the wreſt, and for that muſcle which turneth

turneth the thumbe toward the forefinger: ſometime alſo a peculiar ligament couereth the tendon of the Thumbe.

Finally, the ſixt tranſmitteth the three tendons of the ſecond muſcle that extendeth the Thumbe.

Other Ligaments of the fingers.

Moreouer, euery finger hath ligaments which run throughout their length, ariſing from the ſides of their inner bones which are long and like canales; theſe do containe or keepe the tendons that bend the fingers in their cauities, leaſt in the flexion they ſhould ſtrut vp out of their place or goe aſtray.

To conclude there are other membranous Ligaments, or rather mucous membranes, but redder then the other membranes of the Tendons, which after the manner of Ligaments couer the Tendons that are tranſmitted to the hand and the fingers, involuing them for their more ſecurity, from which ſometimes the muſcles take their originall, & ſo much of the Ligaments of the Hand.

CHAP. XI. *Of the Ligaments of the Holy-bone, the Hanches, and the whole Legge and Foote.*

IT remaineth now that we proceede vnto the Ligaments which tye the Hanch-bones and bones of the *Coxendix* and Holy-bone, as alſo thoſe that faſten the ſhare-bones and which belong vnto the legge.

The Lig. of the hanch.

The ligament which tieth the hanch bone to the holy-bone is a common ligament, broad, membranous and ſtrong, yea in that part where it goeth betwixt the bones it ſeemeth both in ſtrength and thickneſſe to be griſtly, the better to conſtringe and faſten that looſe coniunction. Hence it is ſaith *Bauhine*, that in the trauell of a woman, if the impreſsion be more violent, the connexion wil yeeld ſomewhat.

Of the Holie-bone.

That which tieth the holy bone to the Coxendixe is double; one ariſeth out of the coniunction of the fift and ſixt holy bones, and is infixed into the acute proceſſe of the *Coxendix*, the other ariſeth indeed out of the ſame place, but is inſerted into the poſterior part or appendix of the coxendix to faſten the bones the ſtronger together. Anatomiſts alſo do conceiue that this ligament was ordained to ſuſtaine the right gut with his Muſcles vnder which there is no bone.

The Share-bone.

The ſhare-bones although they be faſtened together by the interpoſition of a griſtle, yet haue they a double Ligament, one which compaſſeth them about circularly, leaſt in the trauell of the birth, or other great and ſtrong motions of the thigh they ſhold be broken, which might well haue hapned if there had bene nothing but bones; the other ligament is that which occupieth the perforation; membranous it is and conſiſteth of fibres that run obliquely downward, for becauſe it was fit that the ſhare-bones ſhould be light a great part of it is as it were turned out, and a ligament ſubſtituted as wel to ſuſtaine the Muſcles that belong to the bone, as to diſtinguiſh the two *Obturators* or the ninth and tenth muſcles of the thigh. The ligaments of the legge are threefold. Some are referred to the articulation of the thigh, others to the articulation of the legge, and others to the articulation of the foote.

Of the legge.

Of the Thigh two.

The firſt.

The ſecond.

The thigh is faſtned to the ioynt of the Coxendix by a double Ligament, one common and membranous which circumcircleth the ioynt, and this the Grecians call ἰσχιον, by the name of the whole ioynt, becauſe it is much thicker, harder & ſtronger then other Ligaments that compaſſe the ioynts; which ſtrength was wel prouided for by nature, for the motions thereof are very ſtrong, and beſides it ſuſtaineth the whole body. This Ligament lieth vpon the ioynt and the necke of the thigh, but groweth onely orbicularly to the root of the great proces that the motions of the head of the thigh might not be hindred. The other ligament of the Thigh is round, and becauſe of his hardneſſe may be called a griſtly nerue. It is ſeated in the cup of the Coxendix, and ariſeth out of the depth thereof where the cauity is lined ouer with fat to make the head mooue more glib, and where the brow or brim of the cup ceaſeth: and is inſerted into the middeſt of the head of the thigh on the top thereof, that it might not eaſily fal out of the ſocket; for the thigh is heauy, and hangeth as it were down from the Coxendix, wherfore when this ligament is laxed and becommeth longer luxation oftentimes enſueth, yea ſometimes it is broken, and although the bone be reſtored, yet the patient is alwaies lame after, becauſe the two bones do not adhere ſo cloſe as they did before.

Next follow the Ligaments of the Legge and the Brace. The first Ligament of the legge is membranous and common, which compasseth the whole knee, except that part which the whirle-bone together with the tendons containing it doth occupy, for that is sufficiently constringed and contained by them. The ligaments of the Legge.

The other is seated in the backside or in the inside of the knee; strong it is and nerious and groweth out of the processe of the legge; and being forked or tined, is fastned vnto the lower head of the thigh on either side. The third is exceeding strong and gristly, growing out of the prominent part of the legge betwixt the cauities thereof, and is inserted into a middle canale or bosome betwixt the two heads of the thigh on the backside. The fourth is slender and mucous in the middest of the ioynt of the knee, & runneth vp from the legge into the thigh, but is not to be found in all bodies. The fift is thicke & almost round, couering the outside of the knee, and it fastneth together the bones of the thigh, the Brace, and the Legge. The sixt is yet smaller then the fift and softer, and is fastened to the inside from whence it ariseth, running obliquely vnto the forside of the leg.

The Legge also is fastned to the Brace, first by a common Ligament in the vpper part neere the ioynt of the knee which embraceth the connexion of the bones on the outside. Againe in the lower part they are ioyned with a common membranous ligament which proceedeth from the legge vnto the *Brace* which it tyeth thereto.

Moreouer, betwixt the bones of the legge and the *Brace*; the space is occupied or taken vp by a Membranous peculiar Ligament which groweth throughout the length of the Brace very fast vnto it. Notwithstanding his originall seemeth to bee, by the course of his descending oblique fibres, from the leg-bone, and his insertion into the Brace. By this Ligament not onely the bones are conioyned, but also the muscles which occupye the leg are distinguished the forward from the backward, and it also affordeth a strength vnto the originall of these Muscles that grow vnto it.

The Ligaments of the foote are very many, whereof some do containe the tendons transmitted into the foote and the toes, and they are three transuerse, others fasten togither the bones of the foote. Of the Foote.

The first is situated before at the ioynt of the foote with the legge, which fasteneth the bones together and transmitteth some Tendons of the Muscles. The second ariseth from the bone of the legge or from the inward ankle, and is inserted into the bone of the heele, and this Ligament maketh three rings, as it were three Ligaments, because there are three cauities for the tendons of the bending muscle of the greate Toe and of the great bender of the other toes which passe that way. The third ariseth from the outward ankle or from the Brace and is implanted into the heele, it helpeth the Coniunction of the bones, and couereth two cauities to transmit vnder it the Tendons of the two Muscles called *Peronæi*, as we haue shewed before in the History of the muscles.

The vse of these Ligaments as it is in the wrest, is, first of all to add strength to containe the tendons of the muscles of the foote that they be not mooued out of their places: from these Ligaments also those tendons do receiue a portion, by helpe whereof they are produced or lengthned togither with the smal strings of the Nerues. In like maner in the lower side of the toes we finde transuerse Ligaments such as are in the Hand, that containe and establish in their office the tendons of the muscles which bende the second and third ioynts of the fingers. These Ligaments do fasten the bones of the foot, and are referred to the instep, to the wrest, the after-wrest of the foote, and to the Toes. *Platerus* addeth to those, a broade Membrane coupling together many Muscles in the Legge and the Ligament in the soale of the foote, which serueth instead of a tendon. Their vse.

There are also Ligaments which binde the *Talus* or pastorne-bone (for so it is called in Beasts, we call it commonly the Cockall) either to the legge or to the bones of the foote; the first of those that binde the *Talus* vnto the bones of the Legge is common and Membranous and compasseth their articulation, the rest are all gristly. The second ariseth from the inside of the *Talus* where it is receyued by the inner ankle, and is inserted into the Legge bone where it regardeth the *Talus*. The third ariseth from the outside of the *Talus*, and is fastned into the Brace-bone that regardeth the same. Of the Talus.

The Ligaments that fasten the *talus* to the bones of the foote are fiue, the first is common and membranous and compasseth the iuncture of the *talus* with the heele; and this *Vesalius* maketh the fift. The second is stronger and gristly and ariseth from the lower part of the *talus* nere his necke, and is inserted into the heele betwixt the two commissures there-

thereof with the *talus*. This Ligament *Vesalius* accounteth for the third.

The third Ligament, *Vesalius* calleth it the fourth, is gristly likewise, and compasseth the whole ioynt on the outside. It ariseth out of the necke of the *talus*, and is fastned to the bone which is like a Boate. The fourth is strong, arising from the necke of the *talus*, and is implanted into that bone which we call the *Dy* or the *Cube*. The fift is strong and gristly, ioyneth the bone of the Heele vnto the Cube, and encompasseth the ioynt round about.

The Wrest.

The bones of the wrest of the foote are coupled with very hard and gristly Ligaments either among themselues or to the bones that border vpon them. To the Neighbour-bones as on the backside the *Cube* or *Dy-bone* to the necke of the *talus*, and the same vnto the heele, so three bones are fastned to the Boat-bone, and on the forefide to the bones of the After-wrist. They are ioyned one to another as in the vpper part or backe of the foote. In like manner in the lower part there is a very strong and peculiar Ligament, which fasteneth them on the outside and tyeth also the hindparts of the bones together, because it insinuateth it selfe among them.

The After-wrist.

Finally, the Ligaments of the After-wrest and the toes which ioyne them together are answerable to the Ligaments of the hande both in their passage and conformation: those also which run in the distances betweene the bones of the wrest are gristly, the rest are membranous. *Archangelus* addeth, that there are common Ligaments which bind & fasten the particular ioynts of the toes, as it is in the ioynts of the fingers. And thus much concerning Ligaments.

The Third Part of Membranes.

CHAP. XII. *What a Membrane is, their Vses and Differences.*

BY the common consent of *Hippocrates*, *Galen* and almost all Physitians ὑμὴν, χιτὼν, μεμβράνη, a Membrane and a Coate doe signifie one and the same thing. I knowe there is sometimes some nice difference amongst the Grecians, but it is of no great consequence, & therefore I would haue you to vnderstand me to meane the same thing, when I speake of a Coate and of a Membrane. The definition of a Membrane is much more necessary, which *Laurentius* hath on this manner: *It is a similar part, cold and dry, engendred of the slimy part of the seede, and therefore broad, thin and fast, the organe of the sense of Touching, keeping, knitting and separating the parts vnder it.*

Definition of a Membrane.

That it is similar it is manifest, because it is vniforme, and though it be wouen with fibres yet are they not conspicuous. I speake here of true Membranes not of membranous bodies, such as are the wombe, the bladder, the stomacke, the guts and such like, which make a part of themselues, and wherein all the three sorts of fibres do appeare. That it is cold and dry, *Galen* teacheth in his Booke *de temperamentis*, but yet it is lesse cold and dry then a Tendon, a Ligament, a Gristle, or a Bone: but more cold and dry then Arteries, Veines and Sinewes. The matter of Membranes is the slimie part of the seede, which by the power of heate is stretched or distended; whence it is that a Membrane may easily be dilated or compressed without danger: onely the Membrane, saith *Galen*, may bee safely distended and contracted, and therefore all parts which were to bee distended and contracted are made membranous. A membrane is broad and extensible to inuest & preserue the part: thight and fast for strength, and beside that it may not so easily receiue an influxion of humors, yet thin, least the waight of it should be offensiue. Notwithstanding though it be thin and appeare simple, yet euery Membrane is double; thorough which duplicature there runne Veines for nourishment, Arteries to conuey life and Nerues to conuey Sense, which vessels being slender and fine, it was fit it should be conueighed betwixt two coats.

The organe of Touching.

The common office of a membrane is to be the organ of the Sense of Touching as the eye is the organ of Seeing, and therefore the sense of a membrane is most exquisite. A Nerue is indeede the conueyer of the spirits and carrieth downe the commandments of the Soule; but as in a muscle it is not the primary organ of motion, as in the eye it receiueth not visible obiects, so it doth not receiue the first tactiue qualities, onely the Membrane is it which we must esteeme the organ of Touching; and if you despoile the partes

of

of their membranes, you make them also insensible. Hence it is that the flesh of the lungs, of the liuer, of the spleene, and of the rest of the bowels is insensible. As therefore the sense of Touching is diffused throughout the whole body of the creature because it is euery where necessary: so likewise are there membranes sprinckled through the whole body almost internally and externally. On the outside the body is inuested with the skinne and the fleshy membrane. On the inside the peculiar membranes are almost infinite.

If it be obiected out of *Galen* in *arte medicinali*, that membranes haue onely inbred not influent faculties such as is sense. We answere with the Reconciler; that *Galen* then speaketh of membranous and broade ligaments which issue from the bones. Obiection.

The three last particles of the definition do elegantly expresse the three principall vses of membranes. They inuest the parts vnder them like a couering, whence they haue the name of coates. They conserue the fibres to make the flesh more firme and stable, they containe the substance of the parts and enclose it round about least it should dissolue and separate part from part. Galen expounded.

Moreouer, they fasten one part to another, from whence proceedeth the admirable simpathy or society of the parts. So by the *periostia* the bones are all continuated one to another; by their common membrane all the muscles are vnited: by the skin the whole body hath his connexion though it be diuers in respect of the structure of parts which are of diuers kindes. The vses of membranes.

Finally, by the helpe of membranes parts are separated from parts, as wee may perceiue in our sections of muscles. There are other peculiar vses of membranes, to sustaine parts as appeareth in the *Mediastinum*: to hinder the refluence of humor as the values that are in the heart, in the great veynes and such like places, and to leade along and establish the vessels that are to be distributed into other parts, as into the mesentery, the kel, & the fleshy membrane.

The differences of membranes are manifold and are taken from their substance, magnitude, site, figure, conformation or texture, and from the nature of the parts which they inuest or containe. If you regard the substance which is the Mansion-house and Ancient seate of the determinate and particular faculty, then wee say that membranes are either lawfull and true or illegitimate. Those are true membranes to which the definition before giuen wil agree, such are the membranes or Meninges of the braine, the *Peritonæum*, the *Pleura*, the *Periostium* and such like; Illegitimate membranes may more truely be called membranous bodies. Of these there are three kindes, some arise from the bones, are broade and insensible, and fasten the ioynts together. Such are called Ligamentall membranes or membranous ligaments. Others are made of the tendons of muscles dilated and so become more like a membrane then a tendon, such are the thin ends of the oblique and transuerse muscles of the *Abdomen*, also the tendon of the muscle that leadeth the leg backward, which they commonly call *fasciam latam* the *broade swath*. To the third kinde I refer those membranous bodies which make parts by themselues, which although they be inuested with coates, yet are altogether made of membranous bodies. Such are the bladders of vrine and gall, the stomacke, the guts, and the wombe, The differences of membranes. The first.

Againe, those membranes which I called legittimate, are eyther of a thin or slender substance like vnto broade cob-webbes, such as appeareth in that membrane or coate of the eie that compasseth the Cristaline humor called *Arachnoides* or the cob-webbe coate; likewise in the *Pia mater* of the braine, and in the coates of the Lungs and the Liuer; or they are thicke as the *Dura mater* and the membrane of the bladder; or they are fleshy as in the face, or altogether neruous.

From the magnitude some membranes are broade and some are long. The figure of membranes is manifolde according to the variety of the parts which they doe inuest. From the situation some are internall some are externall, some supernall some infernall. From the context or conformatiõ some haue fibres of all three kindes, some of two kinds, some of one kind onely: others are without fibres and may be torne euery way as paper may. the second &c

And so much of membranes in generall, of their Nature, vses, and differences. Now we come vnto their history.

CHAP.

CHAP. XIII. *A briefe enumeration of all the Membranes.*

THE number of Membranes is almoſt infinite, and we haue handled many of them before as they fell in our way in the order of Diſſection, nowe we will gather them into a briefe ſum.

The Membranes of the *Embryo.*

The Membranes therefore do ſome belong to the *Embryo* or infant before it be borne, others to the creature after it is borne alſo. The Membranes that inuolue the infant are three, called *Chorion*, *Amnios* and *Allantoides*: the *Chorion* is ſo called, either becauſe it conteyneth the infant, or becauſe it compaſſeth it like a circle or a crowne: it cleaueth wholly to the wombe by the interpoſition of the vmbilical veines and arteries. *Amnios* or the *Lamskin* is the receptacle of the ſweate. *Alantoides*, ſo called becauſe it is like a Haggas-pudding is onely found in bruite beaſtes, and couereth the creature not all ouer, but like a broad ſwath from the end of the breaſt-bone vnto the hips. Of theſe we haue ſpoken more at large in the 5 chap. of the 5 booke, and in the xvi. queſtion of the Controuerſies thereto belonging.

Of the Regions.

The Membranes belonging to the creature after it is brought foorth, are vniuerſall or particular. The vniuerſall we call thoſe which either do inueſt the whole body, as the skin and the fleſhy membrane: or all the parts of the ſame kind as the muſcles and the bones. The Muſcles are all couered with a Membrane which is common to the muſcles, thin, neruous and fibrous, which ſome thinke dooth ariſe from the *perioſtium*: but *Bauhine* eſteemeth it to take his originall from the ſinnewy fibres of the Muſcles themſelues; and it is faſtned to them with thin and ſlender filaments. The vſe of this membrane is to inueſt and circumſcribe the muſcles, to ſeparate them from the other parts and to giue vnto them the ſenſe of Touching. The bones are all cloathed ouer from the crowne of the head to the ſoale of the foote with a membrane which they call *Perioſtium*, neruous, thin and very ſtrong, yet we may except the teeth, the inſide of the ſcull, and the ioynts of the Bones: of it we haue ſpoken in the third chap. of the ſeuenth booke.

The particular Membranes are ſuch as doe inueſt a particular region of the body, or one onely part. The Regions are three, the vpper, the middle, and the lower. The vpper Region is on the outſide couered with the *Pericraniũ*, which is ſeated betwixt the fleſhy mẽbrane and the *Perioſtium*, ariſing as ſome ſay from the proceſſes of the *dura meninx*, as others from Ligaments which paſſe through the ſutures of the ſcull, which Ligaments are ſtretched ouer that part of the ſcull againſt which they iſſue foorth, and ſo meeting together are vnited into a common Membrane. Of this alſo wee haue particularly entreated in the place laſt before named.

The Braine it ſelfe is couered with two membranes called *Dura* and *pia Mater*: Of which we haue ſpoken in the 7 chap. of the 7 Booke, and thither referre the Reader for ſatisfaction, onely heere we remember that they compaſſe not the Braine only, but his Vicar and ſubſtitute the ſpinall marrow, yea all the nerues throughout their generations.

The Middle Region is inueſted round with a membrane which is ſtretched vppon the ribs, excepting the twelfth and is called *Pleura*: of it we haue ſpoken in the 6 chap. of the 6 Booke, as alſo of the purſe of the heart and the *Mediaſtinum* which ariſe there-from in the ſeuenth and eight chapters.

In the Lower Belly, the *Peritonæum* comprehendeth or embraceth all the contained parts, and of it we haue ſpoken at large in the 10 chap. of the ſecond booke.

Of the particular parts.

The particular partes of the body are almoſt euery one couered with their peculiar membranes or coats. The eies haue ſix, called *Coniunctiua*, *Cornea*, *Vuea*, *Aranea*, *Ciliaris* and *Reticularis*, of which we haue ſpoken in the ſixt, ſeuenth, and eight chapters of the 8 Booke. The tongue is inueſted and iudgeth of Sapors by a proper coate ariſing from the third and fourth coniugations of ſinewes. The Gullet, the Mouth, the Palat and the Chops are couered with the ſame coate that couereth the Stomacke; the Heart it ſelfe, the Lungs, the Liuer, the Guts, the womb, the bladder and all the veſſels haue their particular coats: ſo haue alſo the Kidnies and that thick, which they call *Faſcian* or the ſwath-band. The Kell is made of the *Peritonæum* duplicated, ſo is alſo the Meſentery. A world of other Membranes there are, which we haue remembred in their particular places, and therefore liſt not now to trouble either our ſelues or the Reader with them, ſeeing they may eaſily be found by the title of the Chapters in thoſe places to which they belong: we proceed vnto the Fibres, wherein alſo we will be very ſhort.

CHAP.

The fourth part of the Fibres or Villi.

CHAP. XIIII. *The nature of Fibres*

Fibres are called in Greek ἶνες, in Latine *villi*, although that name is ſometimes communicated both to Nerues and to Tendons: ſome call them κτενόιδας, becauſe they are like the ſtrings or lines in plants, or graynes in the woode. *Laurentius* defineth them to be *Similar partes colde and dry ingendered of the Seede, and therefore white, ſolid and long like fine ſpun threds, deſtinated or appoynted for motion, and to hold the fleſh of the parts, wherein they are, together.* The definition of a fibre.

The firſt particles of the definition are ſo manifeſt as they need no explication, the latter which deſigne their vſe or finall cauſe wee will open in a fewe wordes.

There are two eſpecall vſes of Fibres, Motion and Preſeruation of fleſh. Motion according to the Phyſitians is threefold, Animall, Vitall and Naturall. Their 2. vſes.

Animall or Voluntary Motion is performed by the helpe of the muſcles: a Muſcle is moued when his fibres are either intended or drawne toward their originall, and therefore ſayeth *Galen* in the 8. *de Anatom. adminiſtrat.* if you cut all the fibres ouerthwart, the muſcles would preſently looſe all their motion. Motion three fold.

The Vitall motion belongeth to the Heart and to the Arteries, for the heart hath his fibres manifold and very ſtrong by whoſe helpe he is diſtended, contracted and quieteth himſelfe. The Arteries alſo haue their fibres, in their inner coate many tranſuerſe; in the vtter coate oblique and right.

That Motion we called Naturall is moſt manifeſt in Attraction, Retention and Expulſion. Wherefore all manner of Motions proceede from fibres, but their common action is Contraction.

Notwithſtanding we muſt know that theſe naturall Organs had not their fibres allowed them for a peculiar Traction, Retention and Expulſion, but for a common and officiall. So the Stomach, the Guts, the Veines, the Arteries, the VVomb, the Bladder, the Heart and ſuch like, did not ſtand in neede of fibres for their priuate nouriſhment (for the bones and the brayne, and the griſtles and the fleſh of the bowels doe draw their proper Aliment without fibres) but for a common and officiall action. The heart for the generation of vitall ſpirits; the Arteries for the commoderation or tempering of the natiue heate; the Veines for the tranſmiſsion or tranſportation of bloud; the Stomacke for the making of the *Chylus*; the Guts for the diſtribution of the ſame *Chilus*, and the excretion or euacuation of excrements; the Bladder for miction or making of water; the VVombe for Conception and for the Birth. Fibres neceſſarie for officiall actions.

The other vſe of the Fibres is the cuſtody or preſeruation of the Fleſh, as wel muſculous as that which maketh the proper ſubſtance of the part, for the fibres are as it were the firſt *ſtamina* or the warpe, whoſe empty diſtances the fleſh like the wooſe filleth vppe. There are alſo other peculiar vſes of Fibres in the Veines and Arteries, to wit, that therby they might be better extended after all the violent motions of the bloud, and ſo become leſſe ſubiect to miſchiefe. The 2. vſe.

CHAP. XV. *Of the differences of Fibres.*

THE differences of Fibres are to bee taken from their ſite, hardneſſe, ſenſe, texture and from the variety of the Organs. From the ſite they are called Right, Tranſuerſe and Oblique, for if they run lengthwiſe then they are called Right fibres. If they run according to the breadth and interſect or cut the right, then are they called Trāſuerſe or round and circular fibres. If they haue a middle ſituation and interſect both the right and the tranſuerſe at vnequal angles, then are they called Oblique fibres. The office of the right fibres is to draw, the office of the tranſuerſe to expell and that of the oblique to retaine. If the right fibres worke alone then the length of the part is ſhortned and attraction made, if onely the tranſuerſe bee contracted then the latitude or breadth is diminiſhed and expulſion made, but if all the fibres together, the right, the oblique and the tranſuerſe be intended, then the whole part The differences of fibres

is contracted and retention made which alſo they call *Amplexation*. Retention therfore is made not when any one kind of fiber doth worke, but when all are in action together; for ſo when we would firmely retaine any thing in our hands we compaſſe it about on euery ſide, yet the oblique fibres are ſaid peculiarly to retaine, becauſe when they are contracted they do onely imbrace, for they compaſſe the part on euery ſide conſtringing and cloſing together the particles thereof: but the right and the tranſuerſe fibres when they are contracted do not only ſerue for retentiõ, but theſe for expulſion & thoſe for traction.

How Retention is made.

The ſecond difference of fibres may be taken from the hardnes, for ſome are hard & ſtrong as thoſe of the heart, for the feruent force of the inbred heat did require ſo much, as alſo the perpetuall agitation of his neceſſary motion, others are ſofter as the fibres of muſcles.

The ſecond difference.

The third difference is taken from their ſenſe. Of fibres ſome are ſenſible as thoſe which ariſe from nerues. Others inſenſible as thoſe that proceede from the ligaments of bones. If you regard the texture of fibres, ſome are ſo permixed that they make a continuall body, ſo true membranes haue their fibres, yea they are nothing elſe but fibres conioyned one within another. Others are ſeparated from the ſubſtance of the part and haue another vſe beſide the vſe of the part, and theſe are eyther ſimple as in the muſcles (for all the muſcles excepting a very few haue but one kind of fibres, eyther right, or tranſuerſe, or oblique) or manifold, and ſo wouen together that no arte is able to make ſeparation between them.

The third.

The fourth.

So the fleſh of the heart is wouen with al 3 kinds of fibres & in the naturall organs which ſerue for natural motion, if the part haue one proper coat, as a veyne, the womb, the two bladders, then in that coat are al the fibres placed; but if it haue two coats one external the other internal, then are the tranſuerſe fibres placed in the external coat, & the right & oblique in the internal. From this general rule you muſt except the guts and the arteries, becauſe the guts do ſerue for diſtribution and excretion, and the arteries for the expurgation of the heart. Now nature is more carefull for the expulſion of that which is hurtfull then for the traction of that which is profitable.

How the fibres are placed in the Necturall organs.

The laſt difference of fibres is taken from the variety of Organs, ſome ſerue the animall Organs, as the muſcles, the nerues, the ligaments, and the tendons: others ſerue the vitall, as the heart and the arteries: others the naturall, as the Gullet, the Stomacke, the Guts, the Bladders, the wombe, and the veynes. But what euery one of theſe fibres in their ſeuerall courſes doe performe, and how they are diſpoſed in the parts, we haue declared before in the particular hiſtory of euery part.

The laſt difference.

And thus much concerning the fibres: Now we proceede vnto our laſt taske of the Bones.

The end of the Twelfth Booke.

THE THIRTEENTH BOOKE,
Of the Bones.

The Præface.

A Ship that hath bene long at Sea, diſcouered many ſtrange Continents and Riuers, ſtrugled through many hiddeous tempeſts, eſcaped many Rockes and Quicke-ſands; though ſhe hath made no rich Returne, yet when ſhe commeth within ken of her owne Countrey, and ſees the Land lye faire before her: If thou canſt imagine (Gentle Reader) how ſodainly ſhe forgetteth her irkeſome Trauell, thinke alſo how well apaid I am, that I am come within view of the end of this my Tedious Voyage. For I alſo haue trauelled about a *Worlde*, and that for thy behoofe.

In my Iourney, if I haue not made many new Diſcoueries; yet certainely I haue ſounded the Depths more truely, Entered farther into the Continents, Coaſted the Shores, plyed vp the Frythes, Diſcouered the Inhabitants, their Qualities, Tempers, Regiment of Life, their Diet, their Apparrell, their Imployments: And in a worde, I haue made it eaſie for thee to reape the profit of many mens Labors, and of mine Owne. Yet thou muſt Vnderſtand this but as a Letter of Aduertiſement from the Coaſt. I haue not yet brought my Barke about: Many haue ſhunned *Scylla* and *Charibdis*, and haue miſcarried euen in the Mouth of the Hauen, where there are more Rockes then in the Maine; Many Reaches, which we muſt haue diuers windes to fetch, and therefore thou muſt haue Patience if wee make not ſo freſh a Way, but bee conſtrained to winde in by Bourds; and in the meane time, forget not Thou to follow vs with thy Vowes. For this Shore is buttreſt with Rockes on euery hand, the Currants ſwift, the Shallowes many. To breake off our *Metaphor*. The Hiſtory of the Bones is a buſie piece of Worke; their Articulations and Compoſitions many diſſolute and laxe, many ſtrict and cloſe; Their Coalitions hard to be diſcerned, harder to be expreſſed; Their Perforations, Cauities, Boſomes, Appendancies, Prominences and Proceſſes, difficult to diſtinguiſh. Now therefore, if at any time, I ſtand in neede of thy patience; (Gentle Reader) for my Stile heere muſt be abrupt and broken, hard and harſh of neceſsity according to my Argument. If thou canſt finde Profit, loooke not for Pleaſure; and if thou finde it hard to Reape in this vnequall Field, remember hee had ſomething to do that brake vp the Swarth, and ſowed it for thee.

CHAP. I. *Of the definition and differences of Bones.*

THE Bones ſaith *Hipocrates* τῷ σώματι σάσιν καὶ ὀρθότητα καὶ εἶδος παρέχονται, that is, *doe giue to the whole body ſtability, rectitude and forme*: for they are as it were the carkaſſe of a Shippe whereto the reſt of the parts are faſtned, whereuppon they are ſuſtayned and the whole mountenance of the body is built and conſummated. From their figure and magnitude we eſteeme of the figure and magnitude of the reſt of the parts: without the knowledge of the bones we muſt needes bee ignorant of the originals and inſertions of Muſcles, of the courſes of the Veines, of the diſtribution of the Arteries and of the partitio ns of the Nerues. The vniuerſall *ſyntax* or compoſition of the Bones from the Head to the Feete the ancient Grecians called σκελετὸν ἀπὸ τῆς σκελάσεως, as it were a dryed or arrid carkaſſe.

The knowledge of the bone neceſſary.

Galens definitions.

Galen defineth the Bones to be *the hardeſt, the dryeſt & moſt terreſtriall part of the creature.* But this definition doth not pleaſe the pallats of the new writers, as being not exquiſite or Philoſophicall, but made onely for the ruder and more ignorant ſort by way of innitiation. *Laurentius* defineth them more accurately thus.

Laurentius definition.

A Bone is a ſimilar part, the dryeſt and coldeſt of all the reſt, made of the earthy craſſament and fatneſſe of the ſeede by the formatiue faculty, aſſiſted by the ſtrength of heate, for the ſtability, rectitude and figure of the whole body.

The explications thereof

And this definition he ſayth is Eſſentiall, becauſe it deſigneth all the cauſes of Bones, the Efficient, the Materiall, the Formall and the Finall. The forme of ſimilar partes according to Phyſitians is the Temper, becauſe it is the firſt *Power* whereby and wherewith the forme worketh and ſuffereth whatſoeuer the ſimilar part woorketh as a ſimilar. *Siccity*, therefore and *Frigidity* dryeth and coldnes doe expreſſe the forme of a bone. It is drye becauſe of the exhauſtion of moyſture and fatnes, made by an intenſe or high heate. Cold it is becauſe the heate vaniſheth away for defect of moyſture. Theſe primary qualities are accompanied with ſecondary, hardnes, heauines and whitenes. A Bone is hard not by concretion as yce, for then it would be diſſolued by the fire, not by tention as the head of a drum, but by ſiccity as wood.

The forme.

Heauy it is becauſe it is earthy, as alſo becauſe the aire and the water in it are extreamly denſated and thickned: and it is white becauſe it is ſpermaticall.

The matter.

The matter of the Bones is the craſſament of the ſeed, that is, the thicker and more earthy part. *Ariſtotle* cals it *Seminale excrementum*, the excrement of the Seede. For though the Seede ſeeme to bee *Homogeny*, yet it hath ſome parts thicker then others.

There is in it alſo ſomething fat and ſomething glutinous or ſlimy. Of the glutinous part becauſe it may beſt be extended or ſtreatched, are made the nerues, membranes and the ligaments. Of the fatty part are made the bones, and this *Hippocrates* confirmeth where he ſayth, *Where there is more fat then glew or ſlime, there the bones are formed.*

The efficient.

The Efficient cauſe of a bone is the Formatiue power which ſome call the Idoll or the *Idea* of him that ingendreth: this faculty vſeth the heat for his architect, and the ſpirit for his chiefe worke-man, and to theſe the Philoſopher attributeth Ordination, Secretion, Concretion, Denſation and Rarification. The heate therefore drinketh vp and dryeth the fatnes, whence comes hardnes and ſolidity. So ſaith *Hippocrates*, *Bones are condenſated by heat and ſo grow hard and dry.*

Futhermore this heate although it be moderate (for the ſubſtance of our natiue heat is well tempered) yet becauſe it maketh a longer ſtay in a more denſe and faſt matter, it bringeth forth the ſame effects that an intenſe or high heat doth; yea it ſeemeth to burn, whereupon *Hippocrates* doubted not to ſay, *that the generation of bones was made by exuſtion, that is, by burning.*

The end.

Stability.

Rectitude.

The finall cauſe of Bones which *Galen* is wont to call their vſe, is well expreſſed in the laſt particle of the definition. For the primary and moſt common vſe of bones is to giue the body ſtabi'ity, rectiude and figure. Stability becauſe they are as it were propugnacles or defences againſt all violence, beſide they ſuſtaine the body as the baſes or finials of a houſe ſuſtaine the roofe. Rectitude becauſe without bones the creature cannot ſtand vpright but would creepe vpon the ground as a Serpent or a worme. *Hippocrates ſecund*

Epide

Epidemion, maketh mention of a childe borne without bones, yet were the principal parts of his body separated and fashioned, but he was not aboue foure fingers big, and dyed soone after he was borne.

Finally, the bones do giue the figure to the body, because from them dependeth the procerity or stature and the limitation of the growth. For those that haue a great head haue large braines, those that are narrow chested their Lungs also and bowels are but short and narrow: those that haue small iawes haue also small muscles. By reason of this finall cause, which being it selfe immoueable mooueth all the rest, the bones are of that substance which we see, hard, solid, and insensible: hard and solid for so it behooued a pillar or prop to be; insensible *ad ἀνωδυνίαν*, that they should not bee so apprehensiue of payne, for because they sustaine the burthen of the body and are continually moued, they could not haue endured so diuers motions without paine if they had beene sensible thereof, and then the life of the creature should haue beene alwayes sad and querulous. But this want of sense comes not from their earthly substance; for then the teeth which are the hardest of all bones should haue no sense; but because there are no nerues dissemina-ted through their substance. Why bones are insensible.

The differences of Bones are to be taken sayth *Galen* as also the differences of singular parts *from those things which follow the essence, or happen thereto.* The differences of bones.

The essence of a bone, that is, his cold and dry temper doe the Tactile qualities follow, Hardnesse, Softnesse, Density, and Rarity; the accidents are Magnitude, Figure, Situation, Motion, Sense, and the like.

The first diuision therefore of bones is from their hardnesse. Some bones are very hard as those that are called Stony bones and the Teeth; others soft in respect, as the spongy bones and those which we call *Appendices* or *Appendants*; others are simply hard as all the rest. From the hardnesse.

From the magnitude some bones are great, some little, and some moderate. There are among the Anatomists that account those bones to be great which are of a large bore or very hollow and medullous or marrowy. But wee make account of such bones for great as are great in quantity, whether their marrow be lesse or more, for the hanch-bones and the shoulder-blades which are not hollow nor medullous are yet great bones. But because the quantity belongeth to Dimentions and Dimention is three-fold, long, broad and deepe, therefore from the magnitude of bones may be taken a three-fold diuision of them. For some are long as the thigh bone, others are short as the bones of the fingers: some are broad as the shoulder-blade and hanch-bones: others narrow, some crasse or thick, others fine or thinne. Magnitude.

From the figure some bones are plaine, some round, some haue three sides, some haue foure, some are like a boat, some like a Cube or Dye, some like a Mallet, or an anuill, or a stirrop, &c. Figure.

To the figure also we referre, as the best Physitians doe, the passages and cauities, the smoothnes or roughnesse. Some therefore are solid others not solid: some smoothe and some rough; I call that solid which is not hollow. Solid bones therefore doe eyther appeare altogether solid hauing no cauities or dens in the, or at least none sensible as the bones of the eares and the nose; or else they appeare solid on the outside, but within are full of perforations and holes like sponge as are the bodies of the rackbones. To solid bones we oppose those that are hollow, that is, such as haue a sensible or conspicuous cauity, which *Galen* calleth κοιλίαν, a belly.

In these is that substance contained which we properly call marrow, in latine *Medulla*, and therefore such bones we say are medullous, that is marrowy bones.

From the situation there may a twofold difference of bones be taken, because vnder the name of situation we comprehend the position and the connexion. Site.

If you respect their position, some are vpper others are lower, some on the fore-side others on the hindside, &c.

If their connexion with other parts, some are fastened by muscles, some by ligaments, and some by gristles. From motion some bones are mooued as those that are articulated by *Diarthrosis*; some are immoueable, as those that are fastened by *Synarthrosis*. Motion.

From Sense, some bones are sensible as the Teeth, all the rest without sense. Sense.

Finally, we will adde that difference of bones which is taken from the order of generation. For some bones are generated perfect and compleate as the small bones of the eares, the ribs, and the cannell or coller bones The bones of the eares, because it was fitte they should be very hard and very dry the better to resound. The ribs because they were to make the cauity of the chest wherein the heart was to moue from the very birth. The coller bones because they tye the armes to the bodye and strengthen the breast. Other bones are at the first imperfect or little differing from Gristles, as the bones of the Heade and many in the body beside.

And thus much of the differences of bones; now we proceede vnto their parts.

CHAP. II. *The particular parts of bones and an exposition of many appellations or names, of which we shall haue frequent vse in the History of the Bones.*

Three parts of a bone.

IN Bones two things are to be considered; their parts and their cauities. The parts of a bone are three-fold; the principall part whereof the bone consisteth; the parte that groweth to the bone, or the bunching part of the bone. The principall part of the bone hath no proper name belonging thereto, but is called by the name of the whole bone. The part that groweth to the bone is properly called *Epiphysis*. That part which bun-

The principal

cheth or beareth out beyond the plaine sutface is called *Apophysis*. The principall part is the primary bone made by Nature, as a man should say, at the first hand or according to Natures first intention. This is the basis of the rest and occupieth the middle place as being the hardest part; for it is in the generation of bones as in the structure of the vniuerse that which is hard and earthy is placed in the Center.

To this principall part often times groweth another which the *Gracians* call ἐπίφυσις, the *Latines* Appendix, we may call it an Additament, or if you will we may retaine the

The appendix

Latine word Appendix, because it is growne in vse amongst vs. For as if Nature had forgotten her selfe & made the bone too short, she eeketh it out by this Appendix as workmen vse to lay stones or timber vnder their postes or pillars to lengthen them when they are too short. This appendix *Hippocrates* often calleth προσφυσιν, which wee note but by the way.

An appendix therefore is a bone by it selfe, fastened to the whole bone by Symphysis or Coalition; not the vnition it selfe of one bone with another, for so there should be no difference betwixt *Symphysis* and *Epiphysis*, *Coalition* and the *Appendix*. That it is a bone by it selfe is manifest because it hath a proper and peculiar circumscription, and in young creatures may easily be separated without coction or putrifaction; yea it hath often been obserued that in young children it hath beene luxed, if I may so say, by a blow or by a fall and separated from his bone. This Appendix is fastened to the principall bone by that kinde of *Symphysis* or *Coalition* which is made without a *Meane*, because the extremities or ends of the primary bone are softer then their middle parts. Now the substance of an Appendix is rare and lax: but saith *Aristotle*, *Soft things are easily contained in the termination of another, and yeelde vnto them.*

Their Coalition.

This *Coalition* is not made by a plaine superficies or surface but by a mutuall ingresse of a head and a Sinus or bosome, which kind of coniunction doth much resemble that which afterward we shall call *Ginglymos*.

The substance of an Appendix is rare and lax; at first gristly, but in processe of time it

Their substance.

groweth harder and drier because in the motion of the ioynts and their attrition the heat is stirred vppe which drieth and hardneth it. To the extremity of the Appendix Nature hath added a gristle that they might not be so subiect to outward iniuries, or if they happen to be broken yet the softnes of the gristle may helpe them to reunite againe. In old bodies they are so vnited with the principall part of the bone that they can very hardly be separated, yea they seeme to be very parts of their bones. All bones haue not this Appendix, for in the lower iaw there is none. In some bones there is but one, as in the rootes of the ribs and in childrens teeth: in others it is double one at eyther end, as in the Legge, the Brace, the arme, the Ell and the Wand. In others it is treble, as in the haunch bone; some haue foure as the bone of the thigh, three in the vpper part and one in the lower. The *vertebræ* or rack bones haue fiue, two in the transuerse processes, two in the bodies, and one in the Spine. There are many Appendices which are ordinarily by the people taken for processes, as the tooth of the second Rack-bone, the great Trochanter, Styloides, &c.

The

The vſes of theſe *Appendices* or Appendances are diuers, *Galen* acknowledgeth a double vſe: one that in Bones which haue marrow they ſhould ſerue in ſteade of a couer to keepe the marrow in, for that which is hollow and ſolid as is the lower iaw, doth keep in his marrow without an Appendix. Their vſes.

The other for more firme articulation, for a bone is better eſtabliſhed vpon a large Baſis, whereas if the bones ſhould determine into a ſharper poynte, their conſtruction or articulation would bee more dangerous and deceitfull, and the bones eaſily and vppon a light offence would fall out of their ſeates. And herein Art immitateth Nature, for the Baſis or foote of a Finiall or columne for more ſecurity is made large and broad. But becauſe theſe Appendances are broade, Nature made them rare and laxe, leaſt their wayght ſhould preſſe too much vpon the parts vnder them.

To theſe vſes of *Galen* we may alſo adde others, firſt that out of them the Ligaments might take their originall, which either faſten the bones or make the tendons or chordes of muſcles. *Falopius* obſerued that the Ligaments were not extended or lengthned beyond the appendices, as if the appendix bee ſhort the Ligament is alſo ſhort.

Moreouer, the Appendix being ſofter then the bone and harder then the Ligament, interpoſeth it ſelfe as a mediator betwixt the coniũction of the bones, for ſuch is Natures vſe to couple things that are extreame by thoſe that are in a meane.

Adde hereto, that by the interpoſition of the Appendices the fracture of a bone, if it happen, is ſtayed and goeth no further, as appeareth in the ſutures of the head.

Agãine, Appendices were made for the conſeruation of the ioynt. For a bone being very hard, if one hard thing ſnould haue beene committed or conioyned to another, by reaſon of their continuall motion they would haue beene broken or at leaſt worne as the teeth are, and therefore the bones were conſtrued or conioyned by ſofter bodies.

Some out of *Hippocrates* doe imagine that the Appendix was made to b:e as it were the belly of the bone wherein his Aliment is concocted, from whence by degrees it is percolated or ſtrayned into his ſpongy or hollow parts. And thus much of the ſecond part of a bone.

The third part of a bone the Grecians call ἀπόφυσιν, the Latines *Proceſſum*, many other appellations it hath in Greeke and Latin, but wee take the moſt common. In Engliſh we call it a *Protuberation* or *Proceſſe*, and may be deſcribed thus: A proceſſe is a legitimate part of the bone, breaking out of the bone it ſelfe, and bunching beyond his plaine and euen ſurface: ſuch as are the knags of Harts-hornes. Euery bone almoſt hath his proceſſes, but they are moſt conſpicuous in the lower Iaw and in the racke-bones. A proceſſe.

Their vſe we acknowledge to be double: one for the originals and implantations of many parts, eſpecially of muſcles; for vnleſſe the bones had protuberations or productions in them, neither muſcles nor ligaments could grow from them. Another vſe of theſe proceſſes is, that in ſome parts they ſhould ſupply the place of a defence as it is in the rack bones and in the ſhoulder-blades. Their vſes.

The differences of Appendices and Proceſſes are taken from their Figure. For if the protuberation be round it is called a *Head*, whether it be an appendix or a proceſſe. If from a narrow beginning it be by degrees dilated it is called a *Necke*. If it end in a corne or an acute termination it is called κορώνη. An Appendix therfore or a Proceſſe is threefould according to the variety of their figure, a *Head*, a *Necke* and a *Point*. How they differ from appendices.

The *Head* is double, one which is abſolutely called a Head, long and large, ſuch as is the head of the Thigh-bone: the other depreſſed which is commonly called κονδύλιον, wee may properly Engliſh it a Knuckle. The head.

The *Necke* is only of one ſort, herein differing from the head, that for the moſt part the head is an appendix and the necke a proceſſe. The necke.

That which is called κορώνη the *Corne* or Poynt, an acute or ſharpe proceſſe is manifould. One is like a *Bodkin*, another like an *Anchor*, another like a *Crowes-beake*, and another like the nipple of the *Dugges*. The poynt.

The firſt is called *Stiloïdes* or *Graphoeides*; the ſecond *Anchyroeides*, the third *Coracoeides*, and the fourth *Maſtoides*.

Thoſe proceſſes which at the circumference of the cauities doe hang out like lippes and increaſe the depth of the *Cup* are called *Browes* or *Lips* or *Verges* or *Brimmes* or what you liſt, for all theſe things they doe reſemble. And theſe are the parts of a bone in generall.

The

Differences of cauities.

The ſecond thing to be conſidered in a Bone was the cauity, which was made for the articulation or conſtruction thereof. Of cauities there are two ſortes; ſome are deepe and ſome are ſhallow. The deepe cauities which haue high and large browes about them are called κοτύλη a *Cuppe*, and indeed it is moſt like the new faſhioned ſiluer bowles which are rounde and deepe, and the edges hanging ouer their cauities: ſuch are found in the hanch-bone and in the ſhoulder-blade The ſuperficiary or ſhallow cauities are called γλῆναι from the cauity of the eye when the liddes are ſhut: and they are ſo obſcure that at the firſt ſight you may doubt whether they admit another bone or themſelues enter into another: Theſe cauities whether they bee deepe or ſhallow, *Hippocrates* calleth βαθμίδας. And theſe are the Appellations and names which we thought good in this place particularly to explayne, becauſe in the Hiſtory of the Bones you ſhall meete with very frequent mention of them. Now we proceede vnto the ſtructure and connexion of bones.

CHAP. III. *Of the ſtructure and connexion of Bones in Generall.*

Why mans body was not made of one bone.

MAn being created for Vnderſtanding and Action, to receiue infinite images of Senſible things, and to flye or apply himſelfe to the diuers obiects of his appetite, ſtoode in neede of locall motion, but if hee had beene made of one continuall bone, how could he haue bent or extended or compaſſed his body? how could he haue apprehended any thing or moued himſelfe forward to attayne it? No, he muſt haue ſtood like a trunke or a blocke, and the creature that was made to commaund all the reſt would haue beene a right Mauchen or gazing ſtocke to the reſt. Nature therefore for the better accompliſhment of the varieties of motions, hath wonderfully framed the body of man of a Packe or Set of bones, of diuers kinds and manifold figures. And this diuerſity is alſo of as great conſequence *ad ſymptomata*, that when one bone is broken the fracture might ſtop and not offend the reſt. Hereby alſo is there fit way made for Tranſpiration of fumid vapours: hereby are the parts diſcriminated or diſtinguiſhed one from another: hereby is the ingreſſe and egreſſe made for the veſſels. Notwithſtanding though this connexion bee diuers, yet is it ſo ſtrangely fitted together that al ſeeme to be but one: one I ſay either by Continuity or by Contiguity at leaſt. The

What a *Scelcton is.*

vniuerſall compage of coagmentation of the bones is called a *Syntax*, and the packe of bones ſo fitted together is called a *Scelcton*.

The manner of this *Syntax* or compoſition is double, for it is made either by *Articulation* or by *Coalition*. *Articulation* we define to be a Naturall ſtructure of the bones, where in the extremities or ends of two bones do touch one another. So that the whole Nature of *Articulation* conſiſteth in the Contaction of extremities or ends. This Articulation according to *Galen* is double; one laxe and looſe called *Diarthroſis*, for διὰ in compoſition of wordes ſignifieth a ſeparation or looſenes; another ſtrict and ſo compacted that there is no ſpace left for motion. And this kinde is called *Synarthroſis*. The firſt is with manifeſt motion, the ſecond hath no motion at all, or if it haue any it is ſcarcely conſpicuous.

Diarthroſis. *Enarthrosis.* *Arthrodia.*

Of *Diarthroſis* there are three kindes, *Enarthroſis*, *Arthrodia* and *Ginglymos*. *Enarthroſis* is when the cauity that receiueth is deepe, and the head inſerted into it long, and ſuch is the articulation of the Thigh-bone with the Haunch. *Arthrodia* is when the cauity is ſuperficiary or ſhallow, and the head depreſſed or almoſt playne; and ſuch is the articulation of the lower iaw with the Temple-bone and the Nowle-bone with the firſt ſpondell.

Ginglymos.

Ginglymos is when the ſame bone receiueth & is receiued, as it is in the hindges of a dore, wherein the yron that carrieth the hindge and the hindge that is carried doe mutually enter one into another.

In *Ginglymos* therefore the gibbous part of one bone entreth into the hollowneſſe of another; and againe the *Sinus* or boſome of one bone admitteth the gibbous or embowed part of another.

This *Ginglymos* is made two wayes; for either the ſame bone is receiued by one and receiueth it againe, or it receiueth one bone and is receiued of another.

An example of the firſt wee haue betwixt the Arme and the Cubit: of the ſecond in the Racke-bones of the Backe, for the *vertebra* in the middeſt receiueth that ſpondell which is aboue it, and is receiued by that which is vnder it.

Synarthrosis 3.

Of *Synarthroſis* there are alſo three kinds, *Rhaphe*, *Harmonia*, and *Gomphoſis*. *Rhaphe*,

the

the Latines call *Sutura* a seame, for it is like the seame of a garment: and it is double, one toothed like a Saw or a combe, the other plaine like the scales of a fish or the mayles of a Harnesse, or nailes of the fingers one thrust vnder another. The first we find in the sutures of the skull, the second in the Temple-bones. *Harmonia* is an articulation by a simple line, either right, oblique or circular, and so are almost all the bones of the vpper iaw ioyned together. *Gomphysis* is when one bone is fastened into another, as a naile into a boord, and so the teeth are set in the iawes. And these are the two kinds of articulation, *Diarthrosis* and *Synarthrosis*, vnto which we may add out of *Galens* twelfth chapter of his Booke *de ossibus* a third which is a neutrall articulation halting betwixt two, and participating of them both, yet being neither perfectly: and this neutrall articulation, because the motion thereof is obscure, may bee saide to belong to *Synarthrosis*, but in respect of the manner of his composition which is made by a cauity and a head, it may bee called *Diarthrosis*. Such is the articulation of the ribs with the breast-bone and the rackes: such also is seene in the wrest and the instep. And these are the differences and kinds of articulation.

Synarthrosis 3. Kinds.

The Neutrall Articulation.

The other kinde of composition is called *Symphysis* or *Coalition*. For Nature well fore-seeing that the articulation of great bones was not very secure, because they might easily slip out of their seats, she therefore deuised a more streight or neere kinde of coniunction or colligation which Anatomists do call *Symphysis*, wee coalition, which is nothing else but a naturall vnion of bones, by which two bones are continued together and made one, so that the nature of coalition consisteth in continuity, as the nature of Articulation did in contiguity or contaction of extremities.

This *Symphysis* or coalition is double, one with a meane, another without a mean. Those bones that are soft and fungous do grow together without a *Meane*, so all appendancies almost because they are soft and gristly are vnited with bones by coalition, but those that are dry and hard cannot be vnited without the inter-vening of another bodye. That middle body is threefold, a nerue, a gristle and flesh. And hence proceede the three differences of *Coalition*, *Synchondrosis*, *Synneurosis* and *Synsarcosis*. An example of *Sychondrosis* wee haue in the share-bones, and in the lower iaw. An example of *Synneurosis* in euerie *Diarthrosis*, but you must vnderstand that by a Nerue in this place we meane a Ligament. An example of *Synsarcosis* you haue in the bone *Hyois* and in the shoulder-blades, but by flesh here we vnderstand muscles. VVee haue heere added a Table which containeth their pedigree, wherto we wil not so exactly stand, as that there may be no exception taken thereto by curious Schollers, either in the manner of diuision or in the Appellations, although presume such as will be most ready to find fault, will not finde it so easie to Amend.

The Table of Connexions.

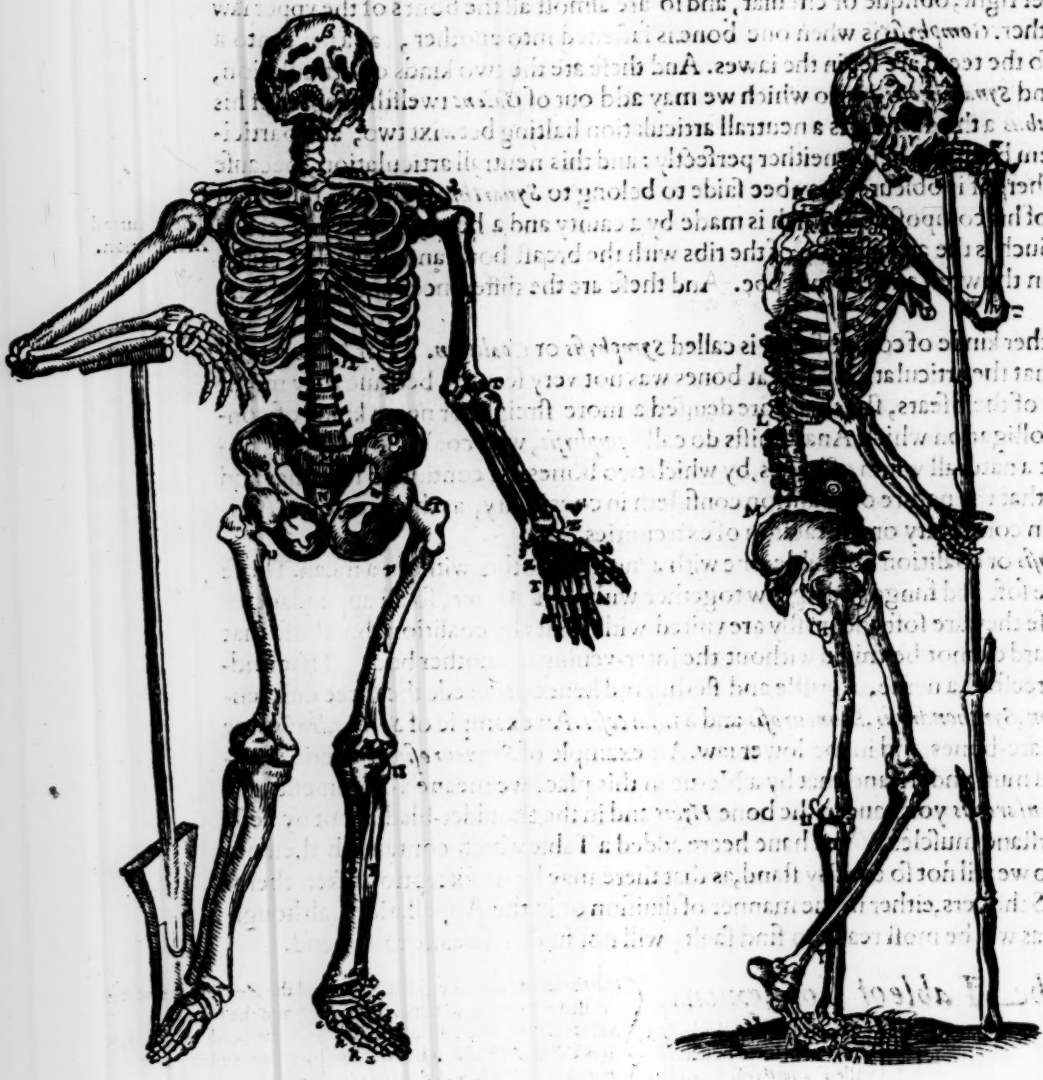
Bones are ioyned or compounded by

- *Articulation*, whose Nature consisteth in contiguity of extremities, & it is threefolde.
  - *Dearticulation* which is a laxe and loose iuncture, called *Diarthrosis*, and is of three sorts
    - *Inarticulation*, when the *Cup* is deepe, and the *Head* long, and it is called *Enarthrosis*, as betwixt the thigh and the Hip.
    - *Adarticulation*, when the cup is shallow, & the head depressed, & it is called *Arthrodia*, as betwixt the lower iaw and the temple-bones, the Nowle and the first rack-bone.
    - *Hinge-hung*, when the same bone receiueth and is receiued, it is called *Ginglymus*, & it is made two wayes.
      - When the same bone is receiued byone bone, and again receiueth the same as betwixt the Arme and the Cubit.
      - When it receiueth one bone & is receiued of another, as a midle rackbone receiueth the vpper & is receiued of the lower.
  - *Coarticulation* which is a strict and well compounded iuncture, and it is called *Synarthrosis*, it is also of three sorts by
    - *Seame* called *Sutura*, and it is double.
      - *Toothed* like a Sawe or a Combe, as the sutures of the seull
      - *Plain* like the scales of a fish as the temple bones with the scull
    - *Harmony* which is like to Cœmentation made by a line which is
      - Right.
      - Oblique.
      - Circular.

      So almost are all he bones of the vpper iaw articulated.
    - *Mortize*, which is when one bone enters into another, as a Tenant into a mortize, so the teeth are fastned in the iawes, and this is called *Gomphysis*.
  - *Galen* addes a thirde which is newtrall or doubtfull; and is neither the one nor the other, but partaketh of them both, agreeing to *Coarticulation* by reason of the obscurity of the motion, and to *Dearticulation* if you regard the composition of the heads and the cauities. Such is the articulation of the ribs with the breast bone and the racke-bones, and that of the bones of the wrest and the Instep.
- *Coalition* or vnion, whose Nature consisteth in continuity, and it is cald *Symphysis*. It is double.
  - Without a Medium or Meane, so do soft and fungous bodies grow together, as almost all Appendancies.
  - With a Mean, as dry and hard bones which are not vnited without the interposition of some middle body: and that is
    - A Gristle such Coalition is cald *Sychondrosis* and it is found betweene the share-bones.
    - A Ligament called *Synneurosis*, and it is found in all Dearticulations.
    - Flesh called *Synsarcosis*, and is found in the bone *Hyois* and in the shoulder-blades.

To this place also we haue thought good to add six seuerall Tables conteining the Sceleton or packe of Bones throughout the whole bhdy, as they appeare before, behinde, & on the side in a man; the Sceleton of a woman; of an infant newe borne, and of two vntimely Births, with their descriptions at large, by which the Reader may be well initiated before he come to the particular Historie.

TABVLA I.



TABVLA III.

TABVLA. II.

Tab.1.sheweth the forpart of the seeleton of a man, that is to say, the whole packe of the Bones and Gristles in a mans bodye, as they appeare on the foreside.

Table 2. sheweth the backside of the Sceleton.

Table 3. sheweth the laterall part of the Seeleton. Wherefore we will put all these three descriptions into one.

A 3. The Coronall Suture called in Greeke στεφανιαία.

B 2 3. The suture like the letter Λ called λαμδοειδῆ.

C 2. The sagittall suture called βελοειδῆς.

D 2,3. The Scale-like *Coniunctio*, cald λεπιδοειδεῖς

4,2,3. *Os verticis* or *syncipitis* the bone of the *Sinciput*, called *Os* βρέγμαλος.

β,1,3 The forehead bone, that is, μετώπη.

γ,2,3. The bone of the Nowle or ἰνίον.

δ,2,3. The bones of the temples or κροταφῶν.

ε 3. An Appendix in the temple-bone like a Bodkin, συλοειδὴς.

ζ 1,2,3. A processe in the temple-bone like the teate of a dugge, called therefore *Mamillaris* and μασθοειδὴς.

E 2,3, the wedge-bone, σφηνοειδὲς.

ι,3, the stony part of the scull.

ϑ 3, A processe of the Wedg-bone, much like the wing of a bat, and therfore called πτερυγοειδεῖς

F,1,2,3. The yoke-bone ζυγῶμα.

G.1.2,3, the lower iaw.

HK,L,M,N,1,2,3. the backe or the spine, ῥαχὶς.

From I to K, the Necke, τράχηλος.

From K to L, the rackebones of the Chest.

From L to M, the rackebones of the Loynes.

From M to *N*, the Holy-bone, ἱερὸν.

N, the Rumpe bone, κόκκυξ.

O 1,3, the brestbone στέρνον.

P 1,3. the Sword like gristle of the brest ξιφοειδὴς

Char. 1,2,3, as farre as to 12 in all three Tables, shew the twelue ribs of the Chest, cald πλευραί.

Q 1, the Clauicles or choller bones κλεῖδες.

R,1,2,3. the shoulderblade, ὠμοπλάτη.

λ,1,2 3. the vpper processe of the shoulderblade, or the top of the shoulder, called ἀκρώμιον.

μ,3,2, The lower processe of the shoulderblade, called ἀγκυροειδὴς.

S 1,2, the bone of the arme, called *Humerus* and ὀβραχίων.

T,V,1,2,3, the Cubit πῆχυς.

X,1,2,3. the wand or the vpper bone of the cubit called κερκὶς.

Y,1,2.,3 the ell or the lower bone of the Cubite, called πῆχυς.

ν 3, the processe of the cubit, ὠλέκρανον.

ξ,1,3, the processe like a bodkin or probe, called συλοειδὴς.

ZZ, 1 2,3, The wrest καρπὸς.

ΓΓ 1,3, The Afterwrest κεφαλὴ καρπίου.

ΔΔΔ, 1, the fingers δάκτυλοι.

Θ,1,2,3. The bones ioyned to the sides of the holy bone on each side one, distinguished as it were into three parts.

ο 1,2,3. the first part called the Haunch bone *Os Ilium* λαγόνων.

π,1.2,3, The second part the bone of the *coxendix* ἰσχίον

ρ.1 ,2,3. The third part, the sharebone *os pubis*, ἦβης.

σ,1,2,3. A gristle going between the coniunction of the share bones.

Λ, 1,2,3, the thigh, μηρὸν.

τ,1,2,3, the greater outward processe of the thigh called *Rotator*, τροχαντὴρ μέγας.

υ,1,2,3, His lesser and inner processe.

Ξ, 1,2,3. The whirlebone of the knee *Patella Rotula*, ἐπιμυλὶς.

Π,Σ.1,2,3, The leg, κνήμη.

Φ,1,2,3, the inner and greater bone of the legge, περονημιον.

Ψ,1,2,3, the vtter and smaller bone of the Legge called the *Brace-bone*, *Fibula* περόνη.

φ,1,2,3. The processe of the Legge or the inner Anckle called *Maleolus internus*.

X,1,2 The processe of the brace or the outwarde ankle, both of them are called in greeke σφυδὼν

Ω,1,2,3, the bone called the cockal *Talus*, *balistæ Os* ἀστράγαλος.

a,2, The Heele *Calx*, πτέρνα.

b 1,3, The bone called *Os Naviculare*, σκαφοειδὲς.

cc, 1.2.3. The wrest of the foote called *Tarsus*, consisting of foure bones, ταρσὸς.

d e.f. 1,2,3, Three inner bones of the wrest of the foote, called by some χαλκοειδῆ.

g,1,2,3. The vtter bone of the wrest of the foote, like a Dye, κυβοειδὲς.

kh,1,2,3, The Afterwrest of the foote called *Pedium*. by some μετάταρσος.

i,i 1,2,3. The toes of the foote.

k,1,2,3. The seed bones of the foote, called *ossicula sesamina*, σησαμοειδῆ.

FIG. III.

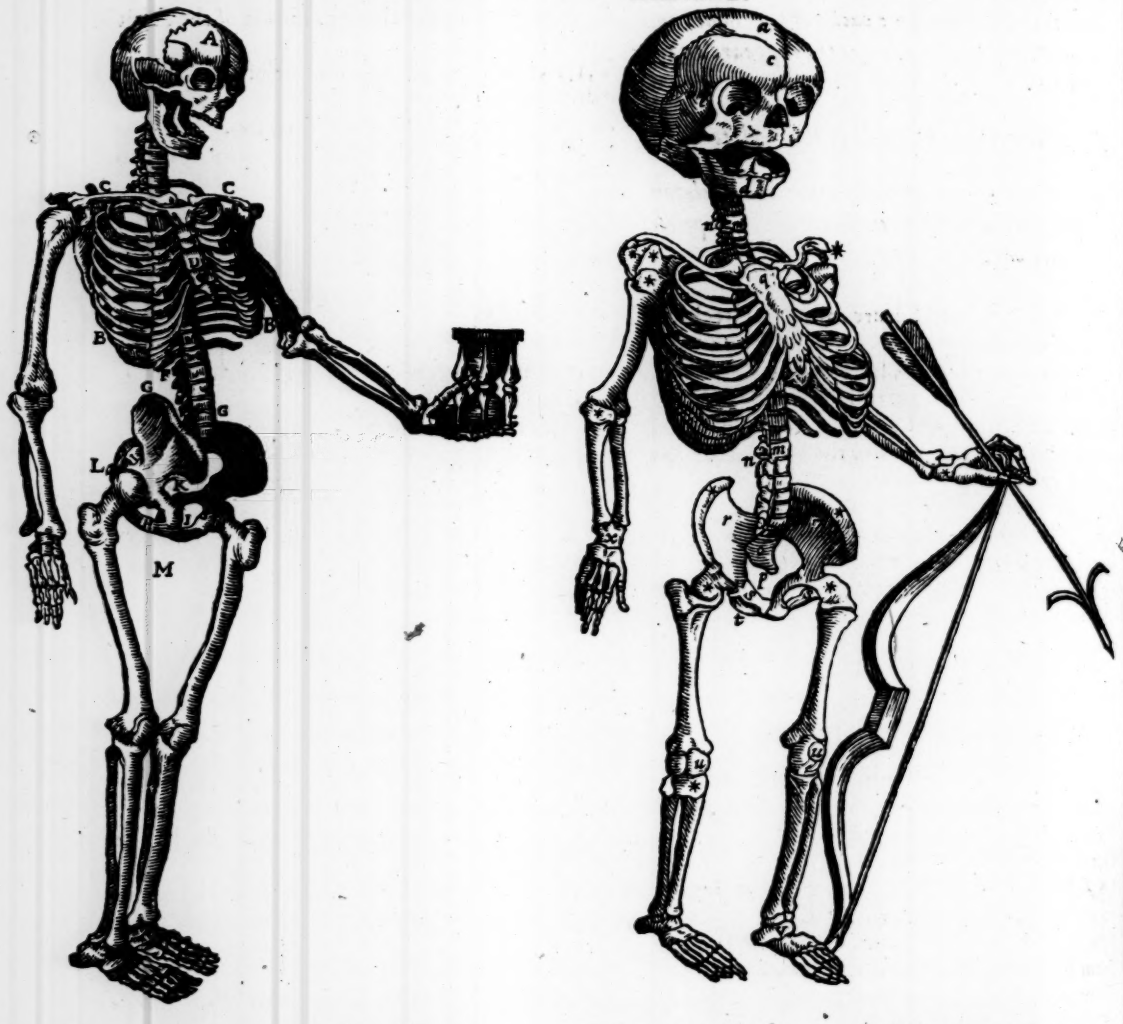


Table 4 sheweth the Sceleton of the bones and gristles of a woman, that it may appeare, all her bones are in proportion lesser then the bones of a man. But in this table onely those parts are marked with letters wherein a woman differeth from a man in her bones & gristles

TABVLA IIII.

A. The sagittall suture descending vnto the Nose and diuiding the forehead bone, which is sometimes found in women, very rarely in men, but alwayes in Infants.

BB, the chest somwhat depressed before because of the Paps.

CC, the coller bones not so much crooked as in men, nor intorted so much vpward.

D, the brest-bone perforated somtimes with a hole much like the forme of a heart, through which veynes do run outward from the mammary veynes vnto the paps.

E, the gristles of the ribs which in women are somwhat bony because of the weight of the Dugs.

F, A part of the backe reflected or bent backward aboue the loines

GG, the compasse of the haunchbones running more outward, for the wombe to rest vpon, when a woman is with childe.

HH, the lower processes of the share-bones bearing outward that the cauity marked with K might be the larger.

I, the anterior commissure or coniunction of the share bones filled vp with a thicke gristle, that in the birth they might better yeelde somewhat for Natures necessity.

K, A great and large cauity circumscribed by the bones of the coxendix and the Holy-bone

L, the Rump or Coccyx curued backward to giue way in the time of the birth

M, the thigh bones by reason of the largeneſſe of the foresaid cauity haue a greater distance betwixt them aboue, whence a so it is that womens thighes are thicker then mens.

Table 5 sheweth the sceleton of a child new borne, wherein the bones are yet either gristly or membranous.

TABVLA V.

a, A thicke and for the most part square membrane betwixt the bones of the forehead & of the Sinciput which filleth vp the parts betwixt them.

c, The bone of the forehead diuided into two equall parts by the sagittall suture.

d, the separation of the lower Iaw into two bones.

e, the Scaly part of the Temple bones which in the middest indeede is bony, but in the circumference membranous.

f, the other part of the Temple bone which maketh a part of the stony bone, where the hole of hearing is gristly.

l, the sockets of the Iawes made to receiue the teeth.

mm, the body of the rack-bone distinct from his backpart.

nn, the backpart of the rackbones consisting of two broade and small bones, and of gristly processes.

o, the Holy-bone made of 5 racks with a gristle betwixt them.

p, The Rump gristle.

q the brest-bone, gristly in the circumference, but in the middest compounded of many bones.

rr, the large part of the Coxendix made of three bones, with a gristle betwixt them

ss. the second part of this bone making the parts of the Coxendix & the share-bones.

t, the third part behind making the same parts with the second.

uu, the whirle of the Knee which is gristly.

x, the wrest of the hand gristly.

y, the Arter-wrest of the foote gristly.

* Although all the appendances of the bones in infants are gristly, yet this * maketh the most notable as those of the arme, the blade, the Cubit, the haunch-bone, the thigh and the legge.

TABVLA. VI.

Table 6. ſheweth the bones and griſtles of an Embryo or vntimely Birth.

The firſt figure ſheweth the Embryo at 42. daies old, already formed and proportioned, when all the bones are like to curdled Cheeſe or to Butter.

Figure 2. ſheweth the tender bones of an Abortiue fruite about 3. months old, which are more griſtly then they are in a child borne in due time.

FIG. II

FIG. I

aa 1. Betwixt theſe letters is that ſpace which on the toppe of the Scull is ſoft and membranous, the Arabians call it *Zeudech*, and commonly it is called *Fontanella*.

a 2, A thick membrane which goeth between the foreheade bone and the bones of the *ſynciput*.

bb 1, the ends of the arme griſtly.

b 2, membranes betwixt the diuiſion of the bones of the head where afterward the ſutures are.

cc 1, The ſoft appendices of the Ell and the Wand almoſt ſeparated from their bones.

dd 1, the appendices of the thigh and the Leg.

ee 1, the bones of the after-wreſt of the foote, altogether griſtly.

z 2, the nayles of the fingers which are conſpicuous euen in an abortiue Infant.

CHAP. IIII. *A briefe diuiſion and Ennumeration of all the Bones in the body.*

THE whole Set or Pack of Bones called *Sceletos* we deuide into three parts; the *Head*, the *Trunke*, and the *Ioyntes*. The Scull which is called *Cranium* or *Calua* conſiſteth of eight bones, ſixe proper and two common. The proper bones are the Fore-head bone, the Nowle bone, the two bones of the *Synciput*, and the two Temple bones, wherein are contained the three ſmall bones of the Eare, the Mallet or Hammer, the Stithy or Anuell, and the Stirrup. The two common bones are the Wedge bone and the Spongy or Syue bone.

The diuiſion of the *ſceletos*. The ſcull 8. 3. of hearing

The Face contaynes both the Iawes, both the vpper and the lower. The vpper Iaw conſiſteth of eleauen bones. The lower Iaw of two onely, vnto both theſe are 16. Teeth articulated by way of mortize or by *Gomphoſis*, of which foure are called *Inciſores* the Sheers, two are called *Canini* the Dog-teeth, and ten *Molares* or the Grinders.

The iawes 13 Teeth 32.

The Trunke is deuided into the Spine, the Ribs and the Bone without a name. The Spine hath foure parts: the Necke, the Backe, the Loynes and the Holy-bone. The Neck hath ſeauen rackebones which are called *vertebræ*. The Backe twelue, the Loynes fiue, and the Holy bone 4. or 6, whoſe extremitie is called *Coccyx* or the Rumpe. The ribs are twelue on either ſide, ſeauen true Ribs and fiue baſtard Ribs, to which are articulated on the foreſide the Breaſt-bone, aboue the Coller bones and on the backeſides the ſhoulder blades. The bone without a name (and I thinke it better ſo to leaue it then to giue it an vnfit name) hath three parts; the Hip, the Hanches and the Sharebones.

The ſpine 18. The rumpe. Ribs 24 Breaſt bone 3 Coller bone 2 Shoulder-blades.

The third part of the *Sceleton* is called the Ioyntes, and there are two of them, the Hand and the Foote. The Hand is deuided into the Arme, the Cubite and the Hand properly ſo called. The Arme hath one bone the Cubit 2, called the Ell and the Wand. The Hand properly ſo called is deuided into the VVreſt, the Afterwreſt and the Fingers. The VVreſt hath eight bones, the Afterwreſt foure, the fingers fifteen, to which you may adde the Seede bones called *Seſamoidea*.

Arme 1. Cubit 2. The hands 54 The ſeed bones.

The Foote is deuided into the Thigh, the Leg and the Foote properly ſo called. The Thigh hath one bone: the Legge two, one retayneth the name of the whole and is called the Leg-bone, the other we call the Brace-bone, in Latin *Fibula*. The Foote properly ſo called hath three parts as had the Hand, the VVreſt, the Afterwreſt and the Toes. The VVreſt which is called *Pedium* hath ſeuen bones: the Afterwreſt *Metapedium* fiue bones:

The thigh 1. Leg 2. Feete 52.

The Toes foureteene. To all theſe wee may adde the bone of the Tongue called *Hyoi* which hath no articulation with any other bone; and this is the briefe ſumme of all the bones in the body. Now we proceed vnto their particular Hiſtory.

CHAP. V. *Of the Sutures or Seames of the Scull, and of the ſubſtance thereof.*

COncerning the Figures or formes of the Head, we haue ſpoken before ſufficiently in the fourth Chapter of the ſeauenth Booke, and therefore here wee will not ſtand either to repeate or enlarge this argument, but come directly to the bones of the Scull.

The Scull

The Scull therefore is called in Greeke κρᾶνιον, in Latine *Caluaria*, and is that bone which compaſſeth the whole brayne, being put vpon it as a Head-peece or Murrion, for more ſecurity and ſtronger defence, becauſe vnderneath it, are contayned ſo noble and neceſſary parts.

Not of one bone.

The Scull alſo for further ſecurity was made round and large, becauſe it was to contayne a great quantity of Brayne and After-brayne. It was not made of one bone for feare leaſt by one wound it might haue beene throughout fractured, but of many ioyned together by ſutures or ſeames, as well for ſecurity as alſo to make the Head leſſe ſubiect to offence: for were it not for theſe ſeames, in vehement motions the bones muſt needes ſtart aſunder.

The ſeames.

The faſhion of theſe Seames is of two ſorts: the one playne and linear like two bords glewed, or ſtones cæmented together: the other indented like the teeth of two Sawes ioyned together, or like a looſe ſeame of a garment when it is ſlackly ſowed. It is very rare to finde the head without ſeames, although *Ariſtotle* report ſuch a thing, as alſo *Pollux* in his ſecond booke, *Herodotus* in his ninth, and *Columbus* vpon his owne experience. Sometimes we finde the *Coronall* ſuture to bee obliterated, ſometimes one of the other, ſometimes in old bodies through length of time and drith all the ſeames do grow together by coalition, as doe the Appendances of bones, and their ſutures are ſo aboliſhed that ſcarce any footſteps of them doe remayne, which in yonger bodies are moſt conſpicuous.

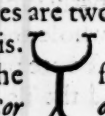
Of all the Sutures ſayth *Falopius* thoſe of the Temples doe continue the longeſt. *Hippocrates de vulneribus capitis*, and *Galen* out of him do ſay, that the ſutures do change their poſition and number according to the different figures of the head, ſo that in thoſe heads wherein the *anterior* prominence is wanting therein alſo is the *Coronall* ſuture abſent, where there is no prominence in the Nowle there is no *Lambdall* ſuture: yet alwayes the *Sagittall* ſuture remayneth, and then the figure of the remayning ſutures is like T. But where both prominences are wanting, there are 2. lines interſecting themſelues through the Scull like X. *Columbus* for this reprehendeth *Galen*, and ſayeth hee hath handled ſixe hundred thouſand Sculs (he meanes a great many in ſome Church yard or Cloyſter) yet neuer found any whoſe figure was not naturall, or which wanted either the *Coronall* or *Lambdall* ſutures. *Falopius* alſo in this is againſt *Galen*, and ſo is *Euſtachius*. *Bauhine* cannot approue it, for ſayth he we often find heads which want either the *interior* or *poſterior* prominence and yet haue all the ſutures. Againe, ſome wee finde without the *Coronall* ſutures, when notwithſtanding the fore head beareth out; ſome without the *Lambdal* ſuture though the Nowle be būching: ſome without the *ſagittal*; ſōe are foūd without any ſuture at al, though no prominence be wanting: not that theſe ſutures are deficient from their originall or from the birth, but they are therefore aboliſhed becauſe they oftentimes grow together whether the head be well formed or no. For if the prominences were the cauſe of the ſutures, then where there are no prominences there ſhould bee no ſutures, but in the ſide of the head at the Eares where the Scull is depreſſed there are ſutures without prominence.

Their differences.

The Sutures are called ῥαφαί, and they are of two ſorts; ſome are proper to the Scull it ſelfe, ſome are common to it with the vpper iaw. The proper ſutures are againe double, True or Falſe: the True are three, the Falſe ſixe. The common ſutures are fiue. The true ſeames are two tranſuerſe, and one lengthwiſe, ſo that together they make ſuch a figure as this.

The Coronall future.

The first or the *anterior* or the tranſuerſe [table 7.[AB] tab. 9. fig. 11.[nn]] is called στεφανῖαια, *Coronalis* the Crowny ſuture, becauſe the auncients were wont to weare their Crownes or Garlands in that place; not ſuch Crownes as Kings weare, and

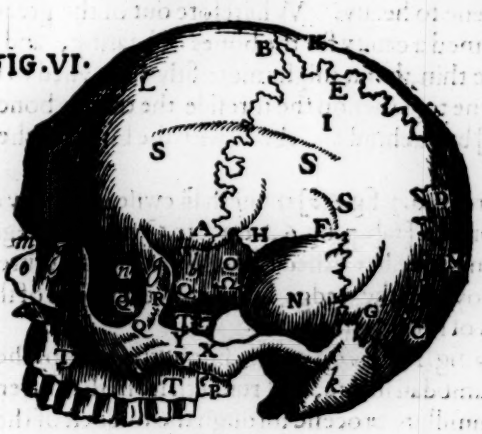


at

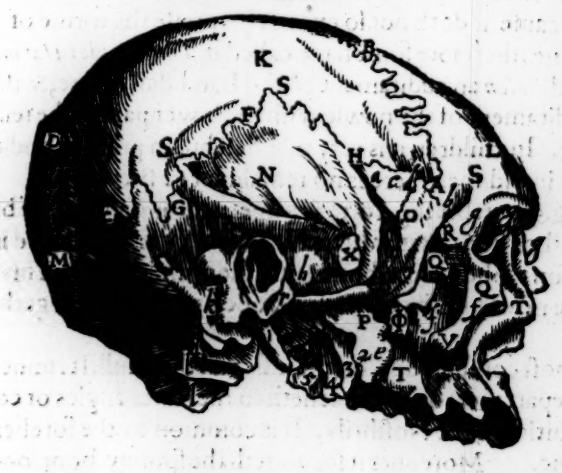
TABVLA VII.

Table 7. sheweth some bones and sutures of the head. Fig. 6 sheweth the left side. Fig. 7 sheweth the right side, the yeke-bone beeing removed. See the description in Lib. 5, folio 438.

FIG. VI.



VII.



at this day amongst vs, Gentlewomen doe in that place weare there Wyers or Tyers of haire, and oftentimes lay some peece of Scarlet or such like vnderneath to defend the mould of the head, (for so wee commonly call it) from the ayer. This suture resembleth a transuerse circle, for it runneth ouerthwart aboue the forehead as farre as to the scaly agglutinations, and it separateth the forehead bone [ta. 7, L from ' to ^x] from the bones of the *Synciput*, or it ioyneth them together.

The second or posterior suture [Tab. 7; c D. tab. 9, ''] is in the backpart of the head, and ascending obliquely from the basis of the nowle to the roores of the mamillary processes, at each eare determineth at the middest of the sagittall suture. This suture because it is like the letter Λ is called *Lambdoides*. It separateth the nowle bone from the bones of the *Synciput* [ta. 7, M from ' ^x] and the temple bones. [tab. 7, N] The Lambdal.

But in those men whose Sculs are large behind this suture is altered into others of diuers formes; somtimes the bone is diuided by a transuerse suture; somtimes it is circumscribed with a double suture as if a greater Triangle should comprehend a lesser; somtimes with a treble, as if a greater Triangle should comprehend two lesser; and these bones so circumscribed are by some called *Triangularia*, and are commended as of much auaile in the *Epilepsie* or falling sickness. The 3 suture is in the midst betwixt the former two, [Ta. 7, fi. 1, ''] and commonly (as you may see in grown bodies) it rūneth from the middle of the Lambdal throgh the middest of the length of the head to the midst of the crowny suture; somtimes it breaketh through it and diuideth the forehead bone iust in the midst vnto the top of the Nose, which is alwayes to be seene in Infants, in some children till they be 7 yeares old, in women but rarely, in men more rarely, and especially in those that haue flat faces. It is called *Sagittalis* because it is straight like an arrow. It diuideth the two bones of the *Synciput*; somtimes also as we haue saide, the forehead bone, and somtimes it cutteth also a part of the Nowle-bone: And thus much of the true sutures. Sagittalis.

The Bastard sutures are so called because they be not so euident and conspicuous as the former, or rather because they belong to the second kinde of seame which is plaine, lying as the scales of a fish one aboue another. Some reckon foure, others fiue, we with *Bauhine* will account six. The first is at the sides of the cauities of the Temples on each side one. [tab. 7, F, G, H] It runneth with a circular passage vpward from the roote of the mammillary processe and passeth downeward vnto the basis. [Tab. 7, fig. 6, from F, G, H, to o] These sutures are not made by coniunction but rather by superapposition, so that the bone of the *Synciput* is by little and little attenuated like the plate of a Iacke or scale of a fish, and lieth ouer the temple bone. And therefore they are not simply called sutures but *Squamosa adglutinationes* and *Squamiformes sutura*. The bastard sutures. The first.

Now the reason why Nature ioyned the bones of the *Synciput* and the temples together like scales was, because she determined to place in the latterall parts of the temple-bones the smal bones of hearing, for which end she stood in need to make the bones of the

hollow, whereas if both bones had beene thicke there had beene no roome for the cauity, and beside the head would haue beene to heauy. Wherefore out of the great bone of the temples being attenuated, is formed a cauity for the bones of hearing, and the other bone of the *Synciput* was also made thin, that it might more fitly be ioyned to the temple bones. These two sutures do ioyne together on the foreside the temple bones with the wedge-bone; [tab.7, fig.6, ᵏ with ᵑ] but behind and aboue with the bones of the *Synciput*.

The fift. The fift, or the second bastard suture [tab.7, fig.6, *b*] runneth likewise obliquely downward at the sides from the top of the former [tab.7, fig.6, from ᵐ to ᵍ] vnto the beginning of the first common suture; [at ᵍ] and this may bee called *Cuneiformis*, the suture of the wedge-bone; for on the vpper part it ioyneth the wedge-bone with the bones of the *Synciput*, on the lower part with the bones of the forehead.

The sixt. The sixt suture [Tab. 8, fig.9, ᵐᵐ tab.9 fig.10, ſ] is on eyther side at the basis of the head; oblique also and continuall with the Lambdall suture, and runneth from the extremity of the same close by the roote of the mammillary processe through the middest of the stony bone obliquely inward to the basis of the head, where it is ioyned to the first rackbone as farre as to the transuerse line; but because it doth not so exactly expresse the forme of a suture, but seemeth rather a simple line, therefore some haue called it *Lambdoides Harmonialis*; others *Lambdoides inferior* and *Galen* an additament of the Lambdall suture; & this suture or line is common to the Additament of the nowle with the lower part of the temple bone and the Organ of hearing. In children it is very manifest but in growne bodies by degrees it vanisheth away so that in old men there is no remainder or shew of it.

The seuenth. The seauenth suture [tab.8, fig.9, ⁿⁿ tab.9, fig.10, t] is a line in the middle of the basis of the head which runneth on eyther side ouerthwart with a short course till it end into the chinke or rift which is common to the wedge-bone with the temple bone. This is common to the Additament of the nowle with the wedge-bone, and ioyneth together the end of the Lambdall suture.

The eight. The eight [tab.9, fig.10, ᵘᵘ] is most conspicuous on the inside of the Scull. It runneth ouerthwart on both sides in the forepart thereof, and reacheth to the lower angles or corners of the spongy bone and the cauities of the Nosthrils. It is common to the forehead with the fore-part of the wedge-bone. Moreouer it separateth the spongy bone on euery side from the fore head bone; which seeme rather to be ioyned by *Lineall harmony* or *Cementation* then by suture.

The ninth. The ninth [Tab.9, fig.10, from ᵘ by K I vnto ˣ on the left side] on the outside, almost in the middest vnder the spongy bones of the Nosthrils appeareth foure square, and runneth obliquely according to the forme of the wedge-bone, so that it is common to the spongy bone as it is referred to the Scull: on the backpart with the wedge-bone, on the forepart and in the sides with the forehead bone: and these are the fiue bastard sutures which with the three true sutures make nine proper sutures of the Scull.

The common sutures of the Scull. The Sutures which are common to the Scull with the bones of the vpper Iaw whereby the processes of the bones of the Scull are fastened on the outside are accounted fiue.

The first. The first is in the outside of the eye-brow, [tab.7, fig.6, 7, ᵍᵍ Tab.8, fig.8, ˣ fig.9, *g*] and runneth outward from the end of the fift suture and the second common suture, and expresseth the right forme of a suture indeed, and it is common to the bones of the forehead and the first bone of the vpper Iaw.

The second. The second which *Archangelus* maketh a proper suture of the Scull and *Columbus* accounteth for the sixt, appeareth in the vtter and laterall part of the orbe of the eye, and as if it were double is distinguished with a long common perforation; aboue it runneth downeward [Tab.8, fig.8, from ˢ to ᵠ and fig.9, to ᵈ tab.7, fig.7, to ᵈ] from the outside of the orbe of the eye and the cauities of the temple bones vnto the foresaide perforation & becommeth common to the wedge-bone with the first bone of the vpper iaw, which maketh the outward angle; below it runneth directly downeward at the sides of the Pallate and the cauity of the Nosthrils from the foresaide perforation euen vnto the roots of the teeth, [tab.8, fig.9, from *d* to *e*] and is common to the wedge-bone with the fourth & sixt bones of the vpper iaw.

The third. The third, which *Columbus* accounteth for the eight, is seated in the inside of the orbe of the eye and the cauity of the Nosthrils, and runneth obliquely outward from the roote of the eye to the top of the Nose, [Tab 8, fig.8, ᵗ ᵗ ᵛ ᵛ ᵗ ᵗ] and is common below, by a

short

TABVLA VIII.

See this description lib. 7. cap. 4. fol. 439.

FIG. IIX.

short cutte to the protuberation of the wedge-bone with the third bone of the vpper iawe; the rest of his passage ioyneth the outward table of the forehead bone, with the second, third, fourth and fift bones of the vpper iaw.

The fourth belongeth to the yoake-bone and runneth obliquely thorough the middest thereof, [ta. 7. fig. 6. x tab. 8. fig. 9. x fig. 8.] and ioyneth the processe of the temporall bone with the proces of the fifst bone of the vpper iaw. The fourth.

The fift is belowe in the cauity of the Nostrilles, and runneth [ta. 8. fig. 9. vnder g] from behinde forward betwixt the processes called the *Vaswings*, and is common to the wedge bone with the partition of the nosethrils. It is also to be obserued that all the coniunctions of the bones of the head which outwardly are sutures, on the inside doe rather seeme to be ioyned by *Harmony* or *Cementation* then by suture: on the contrary sayeth *Eustachius*, in the Scull of an Ape they are each where so obscure, that for the most part they doe not deserue the names of sutures. In seuing men also they are greater and more loose, in others smaller and more compacted. The fift.

The first sort are ofte troubled with paynes in the head from internall causes; albeit *Celsus* in the first Chapter of his 8. book is of another minde; neither ought any man to wonder much thereat, because Anatomy in his dayes was but in the Infancy, and beside that kind of learning among the Romans was but geazon: the other whose sutures are more compacted, are obnoxious or subiect to continuall and great paynes of the head, because the sooty excrements are retayned, which with their acrimony or sharpnesse doe goade the membranes, and with their aboundance distend them.

The vses of these sutures are; first to be vents of the brayne, that the thicker and sooty excrements might exhale. But this was not the only vse, for then the Scull might haue beene bored through with small perforations to haue serued that turne; but it was necessary that the *Dura meninx* should issue forth and be suspended to the Scull, least the hardnesse thereof should presse the brayne or the ventricles therein: beside the Filaments or strings do make the *Pericranium* and the *Periostium*. Furthermore, the sutures were made for the ingresse and egresse of vessels for the nourishment and life of those parts. The vses of the sutures.

Fourthly, that if at any time the head should happen to be broken, the fracture might not run through the whole skull but stay at the end of the fractured bone. Otherwise if a fracture were made in the forepart, the fissure or cleft would passe in the continuation of the bone vnto the hinder part, as it will doe in an earthen pot. Finally, Nature found it needfull that some parts of the scull should be thicker, others thinner, some of one forme some of another; and therefore she thought it fit rather to make it of many bones and to ioyne them together by sutures, then to make it of one onely bone, which must haue had so great variety of parts. We may also adde with *Galen* in the 22. chapter of the 13. book of his Method, and *Falopius* maketh it the 7. vse; that medicines which are to bee applyed outwardly might better enter into the braine and affect it. And thus much of the sutures.

The ſubſtãce of the ſcull.

The ſubſtance of the Scull varieth according to the age of the partie. For in children newe borne it is very ſoft, afterward it is griſtly and membranous, eſpecially about the commiſſures or ſeames [ta.3.ta.4:figure 1.betwixt [a] and [b], eſpecially ta.4.fig.2, betwixt [a] and [a]] and in the vpper and middle part of the head; ſo that in ſome childeren till they haue paſſed ouer ſome yeares it wil yeild to the compreſſion of a mans finger. And this tenerity or ſoftnes of the Scull was very neceſſary, both to make the birth of the infant more eaſie, as alſo for the growth of his head.

But in growne bodies it is altogether bony for more ſtrength; yet not faſt and thin, for then the parts contayned vnder it would not haue beene ſo wel ſecured, for a light violence would eaſily haue penetrated through a thinne bone: nor yet faſt and thicke, for then it would haue beene too great a burden; and therefore it was made neither faſt nor thinne, but thicke, rare and cauernous or full of holes. [ta.9, fig.11, 12, [c] ta.10. figure 14.[c]] Thicke for ſecurity and ſtrength, and rare that it might not bee a burden, porous alſo for Tranſpiration.

The double table.

It is made of a double ſcale [ta.10.fig 14.[a][a]] which ſome call *Diploas* or *Laminas*, we will cal the Tables, which are moſt manifeſt in the bone of the Forehead, in the Temple-bones, in the Wedge bones eſpecially about the browes, or where the Scull was to bee made thick, as aboue where there is no fleſh; below in the Baſis eſpecially about the perforations and the cauities to ſtrengthen them. The Tables although they bee hard and ſomewhat thicke, yet the vtter may ſometimes bee eaten away by the French diſeaſe and the Patient recouer notwithſtanding.

Betwixt theſe Tables [ta.10.fig.14. betwixt [a] & [c]] there is a ſubſtance which ſome haue compared to a Pumie ſtone, fungous and fiſtulated manifould, not onely to make the Scull the lighter, but that in the cauities and pores thereof a marrow might bee contayned, in which marrow the bloud and ſpirits which are powred into it out of the veines and arteries thither ariuing, is boyled for their nouriſhment, and this the Anatomiſts call *Meditullium*. In other parts although it be thinne, yet is it hard and ſolid, as about the Temples where it is very thinne indeed and giueth way to the Temporall muſcles, in the cauity alſo of the eye where notwithſtanding aboue and below it is duplicated.

The ſurface.

The outward ſurface of the Scull is almoſt euery where equall and ſmooth, leaſt it ſhould hurt the *Periotium* wherewith it is compaſſed: yet in the margents or edges of the forehead bone, and aboue the cauity of the eyes it buncheth ſomewhat out for more ſtrength: againe, at the ſides of the Temples the bones are compreſſed for the behoofe of the Temporall muſcles, and in the Nowle it is exaſperated with ſmall knottes or bunches made for the inſertions of the muſcles. The lower ſide or the Baſis is very vnequall, and rough by reaſon of the many proceſſes, cauities and ſwellings of the bones, all which we ſhall make mention of in their particular Hiſtory.

The inner cauity.

The *Internall* cauity is alſo for the moſt part ſmooth, that the *Dura meninx* whereby it is compaſſed might not be offended. In the top as it were of the Helmet it hath ſhallow cauities, in the forehead bone and the bones of the *Sinciput*, whereto the *Dura Meninx* doth grow, & inſcriptions alſo or lines for the courſes of the veines: but below there are diuers productions, extuberations, & ſmall boſomes made to receiue the different figures of the parts of the Brayne, the After-brayne and the inſtruments of the Senſes.

Perforations.

Both Tables are perforated with many ſmall holes, thrilled not in order but wildly and as it were at aduenture, and thoſe tranſuerſe or oblique, through which ſmall veines and arteries do paſſe into the cauity of the inner bones and the *ſinus* of the *Dura meninx* or hard membrane.

Moreouer the ſmall cauities or dens that are in either Table doe make way for the Tranſpiration of ſubtile and thinne vapours, which if they be retayned doe breede giddines and other diſeaſes. For the head is ſet aboue the reſt of the parts as a roofe vppon a houſe that is kept hot but without a chimney: whoſe rafters, becauſe the ſmoake hath no vent, wil become black and ſooty. Beſide theſe, moſt bones of the head haue their proper perforations, cauities, *Sinus* or boſomes and proceſſes, of which we ſhall ſpeak in the particular Hiſtory of each bone.

CHAP. VI. *Of the proper Bones of the Scull.*

THE Bones of the Scull are of two ſortes: ſome belong to the Scull it ſelfe, ſome to the Iaw, which is double, the vpper and the lower. The bones of the Scull in grown bodies are commonly 14. whereof ſome are proper others are common. The proper

per bones are in like manner double, some make the circumference of the scul, and these are commonly accounted sixe. The fore-head bone, the two Bones of the *synciput*, the Nowle-bone and the two Temple-bones. The other serue onely for the sense of hearing which likewise are six, three in each Temple-bone called the Hammer or Mallet, the *Stithy* or Anuile, and the Stirrop. The common Bones of the scul are so called, because they are common to the scull and the vpper iaw, and these are two, the wedge-bone and the spongy bone. In children new borne the Bones of the scull are 22. two of the fore-head, two of the *synciput*, foure of the Nowle, two of the Temples, two Labyrinths, sixe of the Hearing, one wedge-bone, one spongy bone, and two without names. The diuision of the bones of the Scull.

The first is the fore-head bone [Tab.7.fig.6,7 [L]. Tab.8.fig.8.I I] seated before, for it maketh the forepart of the scull both aboue and below, and the whole forehead, and the vpper part of the orbe of the eyes. It is tyed aboue to the bones of the *synciput* [Tab.7.fig.6 [IK]] by the *Coronall* suture; [Tab.7.fig.6[C] fig.7[AB]] belowe, partly to the bones of the scull as the wedge-bone, and on the outside to the bones of the Temples by the *scale-like* suture; [Tab.7.fig.6 and 7[AE]] on the inside by the eight suture, [Tab.9.fig.10.[TV]] as also to the spongy bone which it doth as it were encompasse by the ninth suture: [Tab.9.fig.10 from [V] toward [X]] partly it is committed vnto some bones of the vpper iawe, to the first in the vtter angle of the eye by the first common suture [Tab.8.fig.8.[A] Table.7.fig.6 and 7[E]] againe in the cauity of the orbe of the eye, to the second third, and fourth bones; [Tab.8. fig.8 S,T,V,X] and to the fifte in the top of the nose [Tab.8.fig.8[XZ]] by the third common suture. The forehead bone.

This forehead bone in growne bodies is but one, very rarely two [Tab.3[C] Tab.6. fig. 2 *aa*] though it be alwayes so found in new borne infants, distinguished by the *sagittal* suture; sometimes it continueth so to the seuenth yeare, but is afterward obliterated, the bones growing together. The figure of it is after a sort circular. The substance in a mean betwixt the bones of the *synciput* and the nowl-bone: in infants that part where it is committed with the bones of the *synciput* and meeteth with the *sagittal* suture; is very thin, and in new borne infants [Tab.9.fig.11[Y]] but onely membranous, in growne bodies it is more thin and infirme in the cauity of the eyes and where it is ioyned with the eight bone: in some places also it hath two transparant shels or scales. Toward the sutures it is thicker, that it might fasten more strongly with other bones, as also at the toppe of the nose and aboue the eye-browes, where it is diuided as it were into two partes to make a *sinus* or Denne.

For betwixt the two Tables aboue the Nose in the Region of the Eye-browes, there are large cauities for the most part two, [Tab.9.fig.10 & 11[L]] one on the right hand, another on the left, which are distinguished with bonie Fibres and smal scales. Sometimes also, they are separated and encompassed with a greene Membrane, which contayneth a soft medullous and as it were an oyly bodye. In these bosomes there are perforations which determine partly into the cauity of the nosethrils, and one [Tab.9.figu.10. aboue x] which endeth into the scull presently aboue the partition [tab.9.fig.10[X] T.10.fig.12[X]] of the spongy bone, whereby the organs of Smelling are distinguished. But these bosomes are not found in those that haue flat faces and saddle noses, neither yet where the forehead is diuided. They were formed to make the voice more shril, and thence it is that such as speake in the nose haue them not. The cauities thereof.

Againe, they were made to conteine the aire which is drawne in by the nostrils, that being altred it might first be conueyed to these bosomes, and from thence by degrees to the organs of smelling and so vnto the Braine to make alteration therein: they serue also when the Braine is affected to reduce it vnto his natural state, as when for a moist Braine we appoint a Pomander wrought vp with Muske and Amber-greece; the Muske & Amber warmeth the aire that is drawne in by the Nosethrils and conueyed to these bosoms; and hence it is that oftentimes an odour that is drawne in by the Nosethrils remayning in these cauities, is felt a whole day together in the top of the Nose. Some thinke, as *Archangelus* and *Piccolhominie*, that the matter conteyned in them is somewhat like vnto Oyle, passeth thorough the perforation that is in the greater angle of the eye, and moisteneth the same, whereby it is made glib and his motion more quick and speedy. Their vse.

Beside these, there is also a Den made of a double scale, the vtter scale maketh the vpper part of the Orbe of the eye [Tab.8.fig.8. aboue [A]] and is plaine; the inner maketh the cauity aboue the eyes on either side [Tab.9.fig.2 [Z]] and is not plain but hath inscriptions The Denne.

The perforations.

tions answerable to the winding conuolutions of the Braine, whose protuberating portions it receiueth. A *Sinus* also runneth through the middest of this Bone, as farre as to the spongy-bone, which was made for the third *sinus* of the *dura Mater*, to giue way vnto it that it should not be pressed by the forehead bone.

Holes it hath in the place of the Eye-browes, sometimes two, sometimes three, & three beside peculiar vnto it, one on the inside in the coniunction of the spongye bone with the forehead bone where it passeth into the sinus, of which we haue spoken before. Beside two on the outside at the middle of the browes, on either side one [tab.8.fig.8 AA] which is sometimes orbicular, sometimes long, and endeth into the orbe of the eie; thorough which a branch of the Nerue of the third coniugation is transmitted out of the orb of the eye to the musculous skin of the forehead, haply also vnto the Muscles of the eyelidds, whence it is that oftentimes when a man rubbes his fore-head hee will sneeze vpon it.

His processes.

Finally, the forehead bone sendeth foorth two processes, one vnto the lesser, another to the greater angle of the eye which make the vpper brimmes of his orbe: and so much of the forehead bone.

The *Synciput*.

The Bones of the *Synciput* are so called, saith *Arch.* of *συν* *before*, and *Caput* the *Heade*, because they make the anterior or forward part of the head. In Greeke they are called ἐμπροσθιογκλωβες, which word *Eustathius* vpon *Homer* acknowledgeth to bee giuen, because in Infants that part is not onely tender but very moist: or rather saith *Bauhine*, because thereunder lyeth the moist and soft Braine. They are called in Latine *Ossa verticis*, because they make the heighth or top of the head: [tab.7.fig.6.I K] also *Parietalia* the VVall-bones, & by *Volcher*, the *Bones of Reason* or *Discourse*.

They are two ioyned together in the midst of the length of the head by a suture common to them both, called *Sagittalis*; [Tab.7.fig. 6 A] and so ioyned make the vpper part of the scull, as also the sides for the most part as farre as to the eares. They are fastned also to the adiacent bones, on the foreside to the forehead bone by the coronal suture, [t. 7.fig.6 A B] behinde to the *Occiput* or Nowle by the *Lambdal* suture, [tab.7.fig.6 D C] on either side to the bones of the Temples by the scaly sutures, [tab.7.fig.6 O P R] and finally to the wedge-bone by a part of the fift suture. [tab.7.fig.6 & 7 H, A]

Their forme is almost foure square and almost equally thicke, sauing that they are attenuated where they are ioyned to the Temple-bones.

Forme and substance.

Their substance in growne bodies is hard and solid, yet in respect of other bones very rare and weake, and this haply is the reason why wounds in the *Synciput* are most-what mortall. In infants (I speake not now of Beastes but of men) the anteriour part of these Bones where the Sagittall suture is ioyned with the Coronall [tab.7.fig.6 B N] this part is Membranous and hardneth by degrees, and the two Bones do grow together and are indurated: last of all the Bones of the Head, and some haue thought as *Aristotle* and *Pliny*, that it is not possible children should speake, before the whole scull bee become Bonie.

The breach betwixt them

Because of this softnesse when the Bones are not yet so well growne that they can couer the whole Braine, you may obserue about the crowne of the head as it were a breach or Den, [Tab.9.fig.11 Y. tab.6.fig.11, aa] which the Arabians call *Zeudeth*, the Barbarians because of the moysture and pulsation do call it *Fons pulsatilis*, the beating fountaine. Others call it the *Fontanel*, and indeede in that place at this day wee vse to apply Cauteries, and the Ancients vsed red-hot frying pans in fits of the Apoplexy, for so I may cal them with good warrant: if you wold know the very place of this coniunction in a liuing body, let him lay the roote of the palme of his hand betwixt his browes, and the middle finger will designe the iust place.

These Bones haue on the inside superficiall cauities or small Bosomes, to which the *dura Meninx* growes, as also inscriptions [tab.9.fig.10 and 11, SS] for the vesselles which run from the internall iugulars through the thicke Membrane of the Braine. They haue also some smal perforations, especially outward at the sides of the Sagittall suture which perforate the Bone from one side to another, and transmit small veines for nutrition.

The Nowle-bone.

The Bone of the *Occiput* or the Nowle-bone [Tab.7.figure.6 & 7 M tab.8.figu.9 MM] is called *Occiput*, of *Oc* for *Ob* and *Caput*, because it is behinde the head. Some call it *Os basilare*, the Arabians *os Prorae*, and *os Memoriae*, as if the memory were seated in it. The situation of it is behinde, and it maketh the backward and lower part of the Scul and the middle

dle part also of the Basis. *Platerus* sayth it is alwayes one, but sayth *Bauhine* I haue a Scull wherein it is made of three bones, and *Eustachius* maketh mention of the like.

In children till they come to the end of the first yeare it consisteth of foure bones, one aboue which maketh the greater part of the capacity, and in some bodies is diuided in the middest by the sagittall suture. Another below vnder the great perforation which they call his additament; at the sides of that perforation are the 2. other very thin bones and *gristle bound* or vnited by *Synchondrosis*, for they are deuided by lines filled with a gristly substance, which becomming in time harder is turned into a bone. It is fastned aboue to the bones of the *sinciput* [ta.7,fig.6,[1A]] by the *Lambdall* suture, [tab.7,fig.6,[cn]] at the sides of the Temple bones by the additaments of the same *Lambdall* suture, or by the sixt sutures [ta.8,fig.9,[ch]] and in the middest of the wedge bone [t.8,fig.9,QQ] by a transuerse line or suture, or by the seauenth suture which is common to it with the wedgebone [ta.8,fig.9,[sa].] His connexion.

Figure. The figure of it is almost rounde or rather *dimguliar*, consisting of two circular lines which end into sharpe determinations.

Substance. The substance is hard and fast aboue all the bones of the Scul, and thickest at the *basis* where it is without flesh, and where two *sinus* of the *Dura meninx* are ioyned, [ta.9,fig. 10, vnder [fgb]] for it behoued well that it should be stronger then the forehead bone, because it is behinde where it could not so well haue beene attended vnto. At the sides of the great perforation [ta.8,fig.9,[d] ta,9,fig,10.[d]] it is somewhat thin, (*Aristotle* sayeth the thinnest of all bones, but he mist his marke) and without any cauities or small dens therein, but in the middest to strengthen it the more because of his thinnesse, there riseth and runneth a long prominence [ta.9,figu,10,at [b]] throughout, to secure it if by chance a man should fall backward.

Sinus nine. It hath nine *Sinus* or Bosomes, 7. on the inside, of which two are partly oblique & partly transuerse: on each side one which climeth obliquely vpward & backward through the temple-bones, [ta,9,fig,10,from [b] toward [q]] presently runneth ouerthwart [ta,9 figu, 10, and 11, about [b]] and so they meete in the middest of the Nowle. They are made to receiue two *sinus* of the *Dura meninx* that they should not be compressed by the bones of the Scull.

The third *Sinus* is right, straight, and from the congresse of the former runneth directly vpward, and vnder the *sagittal* suture, and the middle of the forehead bone attayneth vnto the spongy bone, [ta,9,figure 9 at [b]] and this *Sinus* was exculped or grauen in the bone for the third *Sinus* of the *Dura meninx*.

There are two other bosomes seated aboue the transuerse, and distinguished by a right line. Their vse is the better to receiue the Brayne, which is double. There are yet two other large *Sinus* in the *Basis* below the transuerse, [ta,9,fig,10,g] which receiue the prominences of the After-braine, and these are the seauen *Sinus* on the inside. Their vse.

On the outside there are two semicircular, made to receiue the two *anterior* processes, [ta,8,fig,9,[11].]

The perforations. The perforations of the Nowle-bone are fiue: the first [ta.8,fig.,9,[x] ta.9,fig.10,[d]] is in the middest of the *Basis* of the Nowle. The largest of all the inward holes of the head; it is round but somewhat long, through which the marrow of the brayne falleth into the spine. It hath also two other perforations [ta.8,fig.9,[x] ta 9,fig.10,[b]] common to it with the temple bone, on either side one betwixt the head of the Nowle [ta.8,figu.9,betwixt [l] and [l]] and the appendix *Styloides*. These are notable and long perforations, and seeme as it were double, for through it in the lower and vtter part doth passe the greater branch of the internall *Iugular* veine, and the lesser braunch of the sleepy artery: againe, through the vtter and inner part passeth the sixt coniugation of Nerues.

Two other proper perforations it hath [ta.8,fig.9 & ta.9,fig.10,[c]] which are neare vnto the first, running obliquely inward and are orbicular: yet sometimes they are long for the transmission of the seauenth coniugation of sinewes which is presently ioyned to the sixt; sometime also it transmitteth a veine and an artery. Sometimes there is yet found another perforation on either side in the vtter part of the head of this bone [ta.8,fig.9,[y]] which is not very large because it runneth a long course before it gette within the Scull. Some thinke through it there passeth a veine and an artery which did climbe vp the transuerse processes of the Rackebones: but sayth *Bauhine* wee finde this perforation wanting oftentimes on one side, sometimes on both, and then these vessels passe through the two holes last before mentioned.

On

On the outside at the basis the nowle bone is rough and vnequall as well for the originall as for the insertion of the muscles and ligaments.

His processes or heads (for so we called them euen now and according to *Platerus*) are two, [Tab.8,fig.9,ll] broad before, and in infants they haue an Appendix couered also with a gristle, and protuberating more inward then outward, which processes are inserted into the Sinus of the first rack-bone to helpe the motion and articulation of the head. On the backside there ariseth a small processe which is receiued by the first rackbone.

Finally, in dogs from the nowle bone proceedeth another triangular bone situated which goeth betwixt the braine and the After-braine.

The temple bones. The temple bones called ὀστᾶ κροτάφων, are called by diuers names, *Ossa lapidosa*, *Saxea*, *Parietalia*, *Dura*, *Arcualia*, *Squamiformea*, *Squamosa*, *Mendosa*, [tab.7,fig.6,and 7,ᴺ tab.8,fig.9,ᵀᵀ] their principall part is about the sides neare the eares, part of them also in the basis.

The conexiō. In growne bodies they are two, on each side one, but in children each bone by the interposition of a gristle is parted quite through the auditory passage. The footsteps of which diuision do yet remaine at the entrance of that passage. They are conioyned aboue with the bones of the *Synciput* by a proper Scully suture, [Tab.7.fig.6,and 7,G,E,F] sometimes also with the forehead bone below, and on the inside with the Additament of the nowle-bone by the sixt suture; [Tab.8,fig.9,ᵐ ᵐ] in like manner with the wedge-bone: before that is, at the sides, it is ioyned by that suture by which the stony-bone is annexed to the same wedge-bone, [Ta.7,fig.6,from Ω to H] but in the basis on the outside where the cleft is, they are parted asunder. [Tab, 8,fig.9,from ᵃ to ᵒ] Finally, they are ioyned with the first bone of the vpper iaw; [Tab.7,fig.6,ʸ] I meane their processe which is called *Iugalis* or the yoke (for that is a processe of the temple bone) by the fourth common suture.

Their figure and substance. Their figure is aboue ample, round and semicircular, but below it hath no shape but seemeth like a rude rugged and vnequall Rocke.

The substance is also full of variety, for at the basis they are thicke and rough like Rocks whence they are called λιθοειδῆ *Petrosa*, *The rocky or stony bones*. Ascending they are by degrees attenuated, so that they were not so thicke at the basis, but they are as thinne at the top, yea transparent; especially where they giue way to the temporall muscle, and like scales are adioyned by the second kinde of suture to the bones of the *Synciput* which in their descent are attenuated to receiue them: and though the height of the temple bone be but thin in respect of his basis, yet it is harder and faster then the bone of the *Synciput* vnder it to which it is a kind of defence, and therefore cannot be broken without danger of death, although *Columbus* make mention of two children cured of fractures in that place, the one at *Padua*, the other at *Rome*.

Paru. Moreouer if these bones had beene equally thicke throughout and not attenuated toward the top, their very waight, if nothing else, would haue beene burthensome. On the outside they are solid, smooth, and plaine; on the inside because of the conuolutions of the braine it hath many rising inscriptions. Againe in the basis of it wee shall finde one Appendix, three Processes, eight Perforations, and two Sinus or cauities of which we will speake in order.

Appendix. The Appendix is sharpe, long, and slender, and a little incurued like a Cocks spurre. [Tab.7,fig.6,and 7,ʰ tab.8,fig.9,ᵘ] It is commonly called *Styloides*, sometimes *Belenoides*, *Graphioides* and *Plectrum*, that is, the *Bodkin*, the *Needle*, the *Pen*, and the *Cocks spurre*. In children it is gristly, in growne bodies solid and hard, but because it sticketh farre out, a little thing will breake it off, which is the reason why wee finde it so seldome in Sculs gotten out of the ground, yea a little seething will make it fall away.

From this Appendix proceede the muscles which go vnto the bone *Hyois*, the tongue and the lower iaw to draw them downeward, yea the bone *Hyois* it selfe groweth thereto by the interposition of a ligament. So much of the Appendix.

The first processe is on the outside blunt and dull tending downward on each side one, which because they are like the nipple of a Cow are called *Mastoides*, *mammillares*. [ta.7, fig.6,and 7,K.tab.10,fig,8,M,fig.9,K.] It is a thicke processe, spongy within and somewhat hollow, it may be for more lightnes, and it serueth for the insertion of the muscles which bend the head; wherefore it is rough and like a Rocke. The second processe runneth forward from the hole of the eare to the processe of the first bone of the vpper iaw to helpe to make the bone called *Iugale* or the yoke bone, for these twoe processes one of the Temple bone, the other of the first bone of the vpper iaw beeing ioyned with an

oblique

oblique ſuture do make the faſhion as it were of a Bridge or of a yoke. [ta.7.f.6 & 7 V, X. ta.8.f.8 at r] The third proceſſe is on the inſide [ta.9.fig. 10 a] and ſtony, ſwelling out in length; wherin there is a triple or threefold cauity. The firſt is called *Tympanum the drum*, the ſecond *Labyrinthus* the *Labyrinth*, the third *Cochlea* the *Snaileſhel*, where alſo there are 3 bones of hearing, all which becauſe they were made for that ſenſe wee haue handled particularly; the cauities of this ſtony-bone in the 20. 21 and 22 chap. of the 8 Booke, as alſo the three bones of hearing in the 18 chapt. of the ſame Booke, where hee that liſteth may finde aboundant ſatisfaction, at leaſt ſo farre as we could ſerue his turne, for we haue handled them there very particularly. This third proceſſe in infants is called *the bone of the labyrinth*, becauſe it lieth vnder the ſcaly bones, & is ſo ſtraightly faſtned vnto them that at length they vnite; ſo it changeth his name and is called the interior proceſſe of the Stony bone. So much of the Proceſſes. The bones of Hearing, and the cauities of the ſtony bone

The Perforations are of two ſorts, ſix externall and two internall, which doe let ſomething in or ſend ſomething forth, or both. The firſt externall perforation which *Platerus* calleth the third of the temples and the firſt of *Hearing*, [ta,8.fig.9 r] is verie large betwixt the Mammillary proceſſe and the Iugall or yoake-bone; becauſe it intromitteth or giueth way to the entrance of aire and ſounds. It is called by a proper name, *Meatus Auditorius, the hole of Hearing*. The perforations.

The ſecond perforation which *Platerus* accounteth for the firſt of the temples, is in the backſide, nere to but behinde the Mammillary proceſſe [ta.6.fig.9.x] and entreth into the cauity of the ſcull at the tranſuerſe and round ſide of the *Lambdal* ſuture.

This perforation is ſometimes wanting in one ſide ſometimes in both, but when it is there a branch of the externall Veine paſſeth through it.

The third perforation which *Platerus* accounteth for the ſecond of the Temples, is at the ſtony proceſſe [ta.8.fig.9 X] vnder the appendix called the *Bodkin* or *Styloides*. It is a great hole vnequall, and runneth oblique from behinde inward and forwarde, thorough which the greater branch of the Sleepy artery runneth obliquely vnto the fift hole of the wedge-bone, and from thence into the Ventricles of the Braine; by it alſo yſſueth a portion of the third Coniugation of ſinewes. It was bored aſlant or oblique that it might more ſafely paſſe without breaking from behinde forward. Some think the cauſe of the obliquity was, that the ſpirituous bloode might there make a certaine ſtay.

The fourth hole, which *Platerus* calleth the fourth of the Temples and the ſecond of *Hearing*, is likewiſe oblique, double and ſhort. [ta.8 fig.9 V] It intromitteth the Iugular veine, and ſometimes tranſmitteth a ſmall branch of the Auditory Nerue.

The fift, according to *Platerus* the fift of the temples and the thirde of Hearing, is betwixt the Mammillary proceſſe and the Appendix *Styloides*, a round perforation and determineth into the long Canale. It intromitteth the Sleepy Artery and giueth way vnto the egreſſe of a Nerue.

The ſixt, according to *Columbus* the fift, is betwixt the Nowle and the temple-bone great and vnequal, and bored for the egreſſe of the ſixt coniugation of ſinewes, and the ingreſſe of the internall iugular veine vnto the Braine.

The ſeauenth, the ſixt according to *Platerus* of the Temples and the fourth of Hearing, is bored in the backſide of the proces, [Ta.9.fig.10 a] it is long and as it were oual, dilated by degrees and runneth with a blinde paſſage (from whence it is called *Foramen caecum*, the blinde hole) into the labyrinth: into this hole the Auditory nerue of the fifte paire doth paſſe.

The eight, according to *Platerus* the ſeuenth of the Temples and the eight of Hearing, is in the foreſide of the proceſſe; [tab.9.fig.10 againſt a] a narrow perforation and rugged like a rift, and it tranſmitteth from the organ of Hearing a ſmall Artery into the capacity of the ſcull. And thus much of the perforations.

The *ſinus* or cauities of the Temple-bones are two. One outward [Ta.8.fig.9 h] betwixt the hole of Hearing and the proceſſe of the yoake-bone: it is a long cauity, tranſuerſe and cruſted ouer with a Griſtle, and into it the longer proceſſe or the head of the lower iaw is inſerted and articulated, and this *ſinus* ſaith *Columbus*, *Galen* in his Booke *De Oſſibus* hath not rightly deſcribed. The other boſome or cauity is inward, at the backeſide of the proceſſe, long and oblique and common to the Temple-bone with the nowl-bone. [Tab.9.fig.10 from b toward i] And thus much of the proper Bones of the Scull. The Sinus.

CHAP

CHAP. VII. *Of the Bones that are common to the Head and the vpper Iaw, that is to say, of the Wedge and Spongy bones.*

The Wedge-bone.

THE first Bone that is common to the Head and to the Iaw, is called *Sphenoides*, either becauſe it is like a Wedge, ſharpe aboue and thicke below; or rather for that like a VVedge it ſticketh betwixt the Bones before named and thoſe of the vpper Iaw. The Interpreters of the Arabians call it by diuers names, *os Paxillare*, *Colatorij*, *Baſilare* and *Canilla*. It is ſeated in the middle of the baſis of the Heade, yet ſo as that it toucheth almoſt all the bones of the head and the vpper iawe. It is ioyned before, to the fore-head bone by the eight tranſuerſe ſuture, [ta.9.figu. 10. from [x] to [u]] to the ſpongy-bone on the inſide by a portion of the ninth ſuture; [ta.9.fig.10 at the middle [u]] On the outſide at the cauity of the noſtrils, to the partition by the fift common ſuture; [ta.8.fig.9 here [z]] behind, to the additament of the Nowle-bone by the ſeuenth future; [ta.8.fig.9 [nn]] at the ſides to the temple bones by the ſcaly ſuture; [tab.7.fig 7 [a]] to the angle of the Bone of the *Synciput* by the fift Suture, [ta.7.fig.6 and 7 from [x] to [^]] and to the forehead bone by the ſame ſuture. [from [^] to [g]] It is alſo ioyned by his eminences or proceſſes to the Bones of the vpper Iaw, as on the inſide; with the orbe of the eye, with the third Bone of the Iaw by the third common ſuture. In the outſide with the firſt, fourth and ſixt Bones of the vpper iawe by the ſecond common ſuture. [ta.8.fig.8 from S to [s]. and fig.9 from [d] to [e]]

Connexion.

His parts.

In growne bodies it is but one bone, yet at firſt it is compounded of foure Bones with a Griſtle betwixt them, which ſaith *Falopius* in his Obſeruations do not appeare diſtinguiſhed after the ſeuenth month but are vnited. The firſt of theſe foure is the baſis, in middle almoſt of the head ſeparated by a tranſuerſe line from the ende of the additament of the Nowl-bone, and it containeth the Pituitary or Phlegmaticke Glandule, and becauſe it is like a ſaddle, is called the ſaddle of the Wedge-bone. [ta.9.fig.10, [z]]

The ſecond part of the wedge-bone hath no name, and is deſtined to beare vp the vnition of the Optick nerues, [ta.9.fig.10 [b]] and is coupled to the firſt with a plentiful griſtly ſubſtance, toward the palat there is in it a bony naile, whereto is faſtned a long & broad bone which is griſtly in the originall, and is like to the Cowlter that runneth before the Plowſhare. The third and fourth parts of this bone are two proceſſes, on either ſide one like to wings. [tab.8.fig.9.char.1,2,3,4] VVherefore becauſe this bone is made vnequal, with many proceſſes both within and without, it was called by the Auncients πολυμορφον, *Seare-ſhapt*.

His ſubſtance

The ſubſtance thereof is in the baſis denſe and faſt, partly becauſe the head lyeth vpon a baſis, and therefore the Barbarians call it *os baſilare*, partly that it ſhould not be hurt by the excrements that fall downe. In young bodies it is ſolid, but in growne hollowe in the midſt, for the hollowneſſe is made of the ſolid matter diſtended; for as hee that out of a little quantity of glaſſe bloweth a great Violl, ſo Nature according to the vſe ſhee had of this bone, firſt made it denſe and ſolid in children, and then dilated that denſity into a hollowneſſe, which is large and couered with a hard and faſt ſcale or ſhell not at all perforated; as for the inner part, there the ſubſtance is not ſo ſolid but ſomewhat ſpongy.

His proceſſes

It hath many proceſſes, ſome externall, ſome internall; within two on either ſide, which they call κατω δεσις, becauſe they expreſſe or reſemble the lower part of a bed or a Table. [tab.9 fig.10, [aa]] The two forward of theſe are the larger and thicker, and from a broad baſis do end in a ſharpe Cone. The two Poſterior in ſome bodies doe not bunch out at all, but are euen like a Wall, and therefore ſome haue taken it for one Proceſſe.

Their vſe is, that the *Dura Meninx* might be more ſtrongly faſtened vnto the Scull. The outward proceſſes are double: before, one on either ſide neere the partition of the Bones of the Noſethrils and the Palat, in that place where it is ioyned with the vpper Iaw. And theſe proceſſes are likened by Anatomiſts to Bats wings, and therfore called πτερυγοειδεις, for they are thicke and yet end into a notable thinneſſe, almoſt as ſharpe as the edge of a Knife. [tab.8.fig.9.char.1,2,3,4. tab.10.fig.12 HH] They ſerue for a ſeate and a couering to the muſcles that lurke within the mouth: wherefore in the middeſt of them there is a deepe and long cauity from which the muſcle taketh his originall, and whereby it is defended. On the backſide, the bone hath two ſmall points bearing out toward the *Styloides*. The anterior of theſe is blunt, and from it the firſt muſcle of the Chops doth ariſe; the poſterior

ſterior is rough and ſharp from whence iſſueth the 5 paire of muſcles of the lower iaw or very neare vnto it. Finally, there iſſueth another proceſſe from the middle edge thereof which deuideth the pallat into two. There are alſo boſomes or cauities inſculped in this bone. On the outſide in the *wingy* proceſſes as hath bin ſaid: on the inſide one *anterior* & vpper which is tranſuerſe and long [tab,9,fig,10,at c] and prepareth a place for the coniunction of the optick nerues. Another *poſterior* & lovver almoſt foure ſquare, broad and ſmooth very like vnto a ſaddle. Hither the neck of the *Tunnell* reacheth, & in it the glandule vvhich receiueth the phlegme hath his abode, [ta.9,fig.10,r] out of vvhich the ſame moyſture flovveth aftervvard into the pallat and the noſthrils: for from this cauity or boſome, at the ſides on either hand do yſſue 2 canales very ſhallovv. His boſomes.

The vpper of theſe [ta.9,f,10,r] doth attain forward to his ſecond perforation, through which perforation the teares diſtil into the eyes, and the phlegme runneth either vnto the noſe or vnto the choppes through the fourth perforation; through the lower [ta.9,figu,10,O] the phlegme is thought to diſtill into the chinke [ta,8,figu,9,x] which is ſeated betwixt the ſtony bone, the bones of the *Synciput* and the wedge bone, & from thence into the Pallat.

Cauities it hath, two at the ſides of the forenamed boſomes common with it to the Temple-bones and the bones of the *Synciput*; on the inſide concauous or hollow, on the outſide conuex or embowed. [ta.9,figu,10,ss] One alſo and that notable is in the *baſis* of this bone [tab,9.fig,10,vnder t] betwixt the ſurface which is toward the braine, and that which is toward the cauity of the mouth. This cauity in children is not found although the part be ſpongy for a whole yeare; in growne bodies it is hollow and skaley, ſometime His cauities.

TABVLA. IX. *See this diſcription Tab.4.lib.7.fol.441.*

FIG. X.

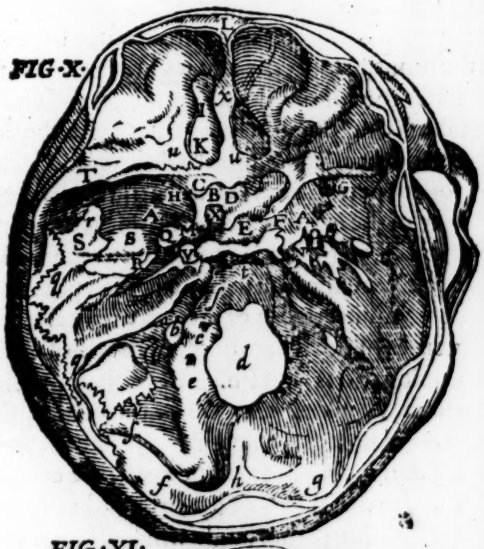


FIG. XI.

not diſtinguiſhed, but ſpongy and made of diuers ſcales, ſometime it it is deuided into two diſtinct [ta,10,fig,12,x] cauities [ta,10,fig,12,cd] which are great or little according to the increment or groweth of the bones. This Cauity is couered with a fine and thin membrane, as thoſe cauities are which be in the forehead and in the cheekes. It is either empty (and therefore ſome haue thoght it was made for the voyce, and that the bones might be the lighter) or in it is contayned a viſcid or tough phlegme. Vnder theſe is another ſmall cauity ſundred into twayne by a partition: [ta,10,fig,12,c] and from the former cauity run two holes vnto the noſethrils, [figure,12,r] haply to giue entrance or entertainment to aire, although *Platerus* ſaith it containeth a medullous ſubſtance therein. It is couered on euery ſide with one continued ſcale, no where bored or hauing yſſue but into the capacity of the noſethrils: yet is this ſcale very thin, and may eaſily be bored through with a ſharpe poynted Probe. If in ſome bodies theſe cauities doe not appeare, then it is made within ſpongy or hollow like a Pumy Stone, ouer the ſurface of which porous ſubſtance are drawne continued ſcales.

It hath ten perforations, ſome in the orbe of the Eye, others in the *Baſis* of the Scull. In the orbe of the Eye fiue, three proper and two common with the vpper Iaw. The firſt of theſe neare the proceſ- His perforations. 5. In the Orbs of the eye.

ſes which make the ſaddle, is circular or round [ta.8. fig.8. ** ta.9.fig. 10 B] made for the tranſmiſſion of the Optick Nerues, and aboue in the outſide it hath as it were a litle angle [ta.9.f,10 C] through which paſſeth one ſmall veine vnto the eye. The ſecond perforation bored in the vpper part is not round but like a ſemi-circular cauity, a ſlit or a long cleft ending into an acute angle, [ta.8,fig.8 ° ta.9.fig.10 °] but the lower part of it is ſomwhat long and orbicular. And of this perforation *Bauhine* vnderſtandeth that of *Galen*, where he ſaith, That the wedge-bone is perforated like a Siue, as if his meaning were that this rift is like a Siue through which the Phlegm doth diſtil; and fitter it was ſaith *Galen* in the 11 *de vſu partium*, that it ſhoulde tranſcolate or diſtill then fall directly through: Otherwiſe we ſhould be continually ſpitting and muſt haue held our mouths open; and therefore herein *Veſalius* and *Columbus* were too apprehenſiue to finde fault with *Galen*, whereas indeede they are rather to bee found fault withall themſelues that they did not ſufficiently vnderſtand him, as we could make it manifeſt if it were a fit place to diſpute ſo nice queſtions in, but we follow our Hiſtory.

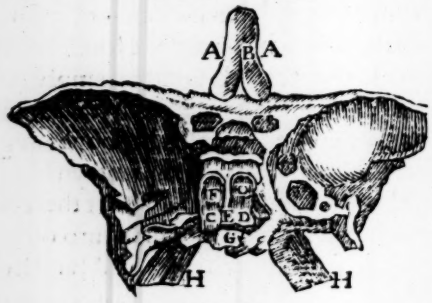
Galen redeemed.

Through this ſecond hole paſſeth the ſecond Coniugation of nerues vnto the muſcles of the eies which ariſe thereabout: alſo, the third paire or the leſſer part of the third coniugation which goeth vnto the skin of the forhead, to the muſcles of the cheekes & of the noſethrils; which yſſueth partly by the hole of the forhead bone aboue the inner angle of the eye, partly through the fourth hole; thirdly, a notable branch of the ſleepy Arterie; fourthly a veine entreth into the cauity of the forehead from the greater vein of the temples; fiftly thereby yſſue the watery humidities of the Braine which are gathered together in the glandule, of which teares are made, and thoſe get out of the cauity of the eye, from thence through the fourth perforation into the fifte, and from the fift they fall into the cauity of the noſethrils. And theſe are the vſes of the ſecond perforation. The third is immediately vnder the forenamed rift. A little perforation it is and perfectly round, thorough which the leſſer branch of the fift coniugation of ſinewes is tranſmitted to the temporall muſcle and to thoſe that lurke within the mouth: ſomtime alſo it giueth way to the leſſer root of the thirde coniugation, which falleth out ſometimes together vvith the ſecond paire. [tab.8.fig.8 **: tab.9 fig.10, **] The fourth perforation in the outſide of the cauity of the eye towardes the noſe is long and large like a rift, and is common to the wedge-bone with the fourth bone of the vpper iaw. It tranſmitteth out of the orb of the eie ſmal nerues of the leſſer rootes of the third & fift coniugations, and Phlegme or rheume with them, all which entred into the orbe by the ſecond hole. [ta.8 fig.8 & 9 °] The fift hole lurketh in the roote of the eye at the ende of the fourth. It is a long, large and noteable perforation, thorough which the rheume which fell out of the ſcull through the ſecond hole, and into the orbe of the eye by the fourth hole, is conueyed vnto the capacity of the noſethrils, [ta.7.fig.7 *] and theſe are the fiue perforations of the wedge-bone in the orbe of the eye.

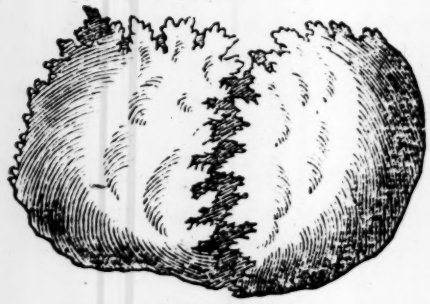
TABVLA X.

See this Table with his deſcription in fol. 443.

FIG XII

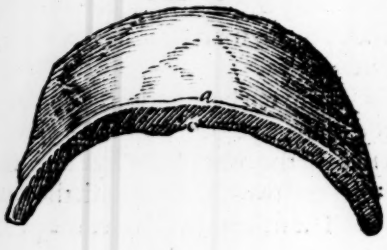


XIII



5. Out of the baſis of the ſcull.

XIV.



In the baſis alſo of the Scull it hath fiue perforations. The firſt within, at the ſide of the boſome where the Glandule is ſeated: a wide, ſhorte and orbicular hole it is which admitteth the great branch of the ſleepy Artery from the ſecond hole of the templebone into the ſcull. [tab.9 fig,10 X] The ſecond, is on the outſide ſomewhat long and large, which tranſmitteth the greater rootes of the third and fourth coniugations of ſinnewes,

com.

commonly ſo called. [tab.8.fig.9 ϰ. ta.9,fig.10 ϰ] The third adioyneth on the outſide to the ſecond, but is much leſſe and round, made to admit the branch of the internal Iugular veine which entreth into the ſcull and into the ſubſtance of the *Dura Meninx*; [tab. 8. fig.4 ᵃ Tab.9.fig.10 ᵃ] ſometime at the ſide of the ſixt perforation wee finde ſmall holes prepared to admit a branch of the foreſaide Veine. [Tab.9.fig.10 ᵡ] The fourth is at the Noſethrils, a long hole and running directly outward, through which a braunch is conueyed into the cauity of the noſethrils [Tab.9.fig: 10 V] from the greater branch of the ſleepy artery. The fift and laſt perforation of the wedge-bone is in the pallate at the extremity of the winged proceſſe: it is large and almoſt oual, that through it the third coniugation of ſinewes and the fourth might yſſue: [ta.8.fig.9 μ ν] The third into the tongue and his coate to the teeth and the lips to giue them ſenſe; the fourth to make the coate of the pallat. And thus much concerning the wedge-bone.

Of the Spongie Bone.

The ſecond Bone that is common to the Head and the Iawe, which *Veſalius* and *Columbus* make the eight bone of the head, Anatomiſts haue called *Ethmoides* or the *Syue*, not becauſe it is full of holes and dennes, but becauſe theſe holes are not direct (though ſome direct there be) but curued or writhen as are the holes of a Sponge. It is more truly called *Spongoeides* or the Spongy-bone, which name *Hippocrates* gaue it, as *Galen* witneſſeth in the 7 chap. of his 8 Booke *De vſu part.*

It is ſcituated in the forepart of the ſcull before the *Meninges* and filleth vp almoſt the whole cauity of the Noſethrils. It is ioyned to the middeſt of the forehead bone, [ta. 9. fig.10 ϰ] and is diſtinguiſhed on the backſide from the wedge-bone by the ninth ſuture of the head, if that be not rather a harmony or Cœmentation then a ſuture: [ta.9.fig. 10 a boue ᵃ] on the outſide it determineth at the ſecond Bone of the vpper iawe, *Columbus* ſaith at the ſecond and the third. Situation.

The figure of it is like to that ſquare that on one ſide is longer, on the other broader: but he that would ſee the true figure of the bone muſt take viewe of it in a childe but of one year old, for afterward it cannot be ſeuered from the reſt of the bones without breaking. At that age alſo a man may perceiue how that which is accounted by *Veſalius* and *Archangelus* the third bone of the Iaw which maketh the thin but ſolide and plaine part of the orbe of the eye, and the Spongy bone of the noſethrilles which is oft eaten out by the French diſeaſe, and the Syue-bone are all parts of one and the ſame bone. For, indeede there are foure parts of this bone. Figure. 4 Partes.

The firſt is the vpper proceſſe in the middle of the bone, long and triangular, ending in a ſharpe point and reſembling a Cockes-combe; ſometimes it is thin and broad; ſometime thicke and diuideth the whole bone like a partition: it diſtinguiſheth alſo the Mammillary proceſſes of the Braine. To this part alſo the third ſinus of the *dura Meninx* which diuideth the Braine groweth very ſtrongly [ta.9.fig:10 ϰ ta.10.fi.12 ᵃ]

The ſecond part of the Spongy-bone is on either ſide at the proceſſe where it maketh the cauity of the ſcull. It is throughout perforated like a Syue with abundant, ſmall and oblique holes. [tab.9.fig.10 ᵡ ᵡ.tab.10,fig:12 ᴬᴬ] In dogges theſe holes are much larger, whence haply it is that their ſmell is ſo briske and ſharpe. It is compaſſed with a thin Membrane which is perforated like the Bone, and that indeed was the reaſon why it was called the Syue-bone or the Collander.

The third part is a lower proceſſe oppoſite to the vpper which diſtinguiſheth or ſeparateth the vpper part of the noſethrils.

The fourth part and the laſt like a ſponge or a *pumi* ſtone is porous and full of ſmal cauities, whereupon the whole Bone is called *ſpongoides*. This part is ſeated in the vpper part of the noſethrils, and accompliſheth or perfecteth the inſide of the orbe of the eye. It is ſpongy and full of oblique perforations that the cold aire which we breath in, or impure aire might not inſinuate it ſelfe directly into the Brain vnbroken or vnaltred, whereby it might be too much refrigerated or otherwayes annoyed; for being a while retained in theſe oblique paſſages it receiues a muration, and is made more like to the temper of the Brain. And here *Galen* in the ſeuenth chap. of his eight Booke *de vſu part.* doth woorthily commend the infinite wiſedome of our creator, who hath diſpoſed of all the partes of our bodies, as was moſt fit for our vſe and preſeruation. This bone therefore is manifold: at the head perforated like a Syue, at the cauity of the noſethrils ſpongy, at the orbe of the eye plaine and broad. And hence it appeareth that the ſubſtance of this bone is ve- The wiſdome of God.

ry thin thrilled, alſo manifould but finely and obliquely, finely or with a ſmall bore leaſt any thicke body that flies in the ayre ſhould get into the brayne.

The vſe of the perforations. The vſe of the perforations is, ſayth *Galen* in the ſixt Chapter of his 8. boode *de vſu partium*, that through them the ayre might be breathed in for the generation of Animall ſpirites: againe, that with the ayre odours or ſauours might aſcend into the brayne, and therefore the Mammillary proceſſes or the organs of Smelling doe runne out hard vnto theſe perforations: hence it is that thoſe that be troubled with the *Coriza* (we call it commonly the *Poſe*) cannot ſmell, becauſe theſe perforations are ſtopped vp with Rheume. There is alſo good vſe of them in diſeaſes of the brayne, that the ayre being altered by medicines, and retayned longer in theſe cauities, might woorke more powerfully vppon the brayne.

Galen in the place laſt before quoted addeth another vſe. By theſe perforations ſayth he, when neede is, aboundance of excrements may be ſuddenly and togetherward auoyded: ſo likewiſe ſayth *Laurentius*, but maketh it a ſecondary vſe, yet *Platerus* denyeth that there can be any ſuch confluence, vnleſſe it be vnnaturall or beſide nature.

Finally, in the backeſide of this bone on either hand there is a ſemicircular rift or cleft, as if it were pinched with a mans nayles, which eſtabliſheth [ta.9.fig.10.below ᵃ] the *Dura meninx* faſtned thereto and perforated with diuers holes. And thus much concerning the ſpongy bone which is the laſt of the bones of the head or of the Scull. Now wee proceede vnto the bones of the Noſe.

CHAP. VIII. *Of the Bones of the Noſe and of the Yoke bone,*

THE Bones which make the cauity of the Noſtrilles are of two ſorts: ſome which may be ſayde to bee proper to the Noſe although indeede they bee bones of the vpper Iaw, others are common. The proper bones are three, two externall and the third internall, and theſe runne onely vnto the middle of the Noſe, for the reſt is altogether griſtly.

The 2 externall bones. The two externall bones which make the riſing bony part of the Noſe are one on each ſide, ſmall and quadrangular, but one ſide is longer then another. Theſe are thin but very ſolid, perforated with ſmall and common holes and are portions of the fift bone of the vpper Iaw, [ta.8,fig.8,ᶻᶻ] which portion aboue is ioyned in a ſhort cut by the third common ſuture with the forehead bone betwixt the browes. [ta,8,fig.8,ᶻʸ] At the ſides they are vnited by a proper ſuture, *Archangelus* calleth it a *Harmony*, running along the ſide of the Noſe [ta.8.f.8.from ᵉ tovvard ʸ] vvith the 4 bone of the iavv [ta,8,fig.8,ᵃ f.9,ᵛ ᴀ] which maketh the ſides of the noſtrils, the lower part of their holes, & the greateſt part indeede of their capacity. Below they are vnited by griſtles, wherfore at their end they are rough vnequall that the griſtles and the bones might cleaue faſter together. On the inſide they are ioyned by another common line and cleaue faſt vnto the partition of the *Syue-bone.*

The 3 internall. The third bone we ſayd was inward within the cauity of the noſtrilles: broad it is & thinne at the roote, but before and aboue thicke: it tendeth vpward to the holes of ſmelling and downeward to the Pallat. This is placed betweene the two former and adhereth, yea is vnited to a proceſſe of the Syue-bone or the eight bone of the head. [ta,9,fig 10.vnder ᵃ] It is called *Septum* or the partition, becauſe it diſtinguiſheth the cauity of the noſtrilles into two parts. [ta,8,fig,8,O] It is ioyned to the two former or the fift bone of the iaw by the firſt internall ſuture. [ta,8.fig,8,vnder ᶠ] On the foreſide it determineth into the middle griſtle wherewith it is vnited. At the inner hollownes of the Noſe toward the Pallat where this bone is ſeuered from the wedge-bone, it is deuided throughout his length by a broade rift, paſſeth throughout the Noſe, and hauing his *Baſis* which is thicke and broade bifurcated it lyeth vppon the wedge bone, reſembleth the ſhare of a Plough [tab,8,fig,9,ᶜ] and his edge is ſinuated or vnequall. Finally, it is ioyned on the inſide to the fourth & the ſixt bones of the Iaw by the ſecond internall ſuture. [ta,8,fig,8,g] Theſe are thoſe three we call the proper bones of the Noſe.

The common bones. The common bones are, firſt that which we called the ſpongy bone which cleaueth to the top of the roote of the Noſe, for in the inſide of the Noſe at this bone there are found two fungous and ſpungy portions which fil the vpper cauity of the noſtrils, and are made to aſsiſt the voyce and the ſmelling. Their forme is very diuers, but they ſeeme to bee moſt like ſcales growing one vpon another. They are vnited with the Syue-bone, from whoſe

whose outward sides they yssue, so that sayth *Bauhine* for my part I beleeue that they arise from it and are parts thereof, although they do not grow to the partition. Againe they are vnited a good way in their sides to the forehead bone: on the inside they are so conioyned with the third bone of the Iawe, that *Falopius* hath referred this third bone of the iaw to the additaments of the Syue-bone and that not without good reason. In these the ayre which is drawne in together with odours receiues an alteration. They are vnequall and rough, that the excrement of the Nose should not perpetually distill downe, and in the French disease they are easily gnawne asunder.

Below at the pallat, the fourth bone of the Iaw [ta.8,fig.9,λ] and the sixt [ta.8,fig.9,ν] together with his fellowe doe make the greatest part of the capacity of the nostrilles where they open backward into the Chops.

In a word this whole bony cauity of the nostrilles is formed of bones both on the inside and on the outside. Without, either before or at the sides, outwardly and before, aboue by the fourth [tab.8,fig.8,ᵃ] and fift [ε] bones of the vpper iaw to which gristles are adioyned. Below at the pallat, by the fift [tab.8,fig.9,λ] and the sixt [ν] On the inside by the spongy bone of the head, [ta.9,fig.10.κ] by the two spongy bones of the nostrilles, & by the partition of the nostrilles: [o] at the sides the cauity is made vp by the second, [tab.8,fig.8.ϖ] the third [ϴ] and the fourth [from ˣ to ᵃ] bones of the vpper iaw. A briefe of the bones of the nose.

Of the Yoake-bone.

The Yoake-bone [tab.7.figur.6.ʸᵃ] is called ζυγομα, because it is made of two bones ioyned together. It is seated in the side of the face vnder the orbe of the eye. This is no peculiar bone though it haue a pecular name, but is compounded of two processes of two seuerall bones: one of the Temple bone another of the first bone of the vpper iaw, which two processes are in the middest ioyned together by an oblique suture [ta.7.fig.6.ˣ table 8.figur.8.ʸ] and so make one bone like a yoake, although me thinks it is better compared to a bridge. On the outside it is gibbous, within hollow. The rootes on either side are thicke, but the middle of the processe which yssueth out of the Temple bone is but slender. The yoake bone,

The substance of it is hard and almost solid, almost I say, for it hath a cauity in it, such as it is, wherein it contayneth marrowe for his nourishment, yet is it somewhat solid too, the better to defend the Temporall muscle, especially his Tendon, before which it is placed, from outward iniuries: beside the muscle called *maxillaris* taketh his originall therefrom, and againe it strengthneth the Scull which is there but thinne. And finally sayeth *Platerus* and with him *Laurentius*, it giueth a great strength vnto the orb of the eye which swelleth out a little aboue it. And so much of the yoake bone: now we proceede vnto the vpper Iaw. His substace,

CHAP. IX. *Of the Sutures and Seames of the vpper Iaw.*

THE Iaw is called by *Aristotle* σιαγων, because when we hould our Iawes together wee keepe silence, which the Grecians call σιγαν, it is also called γενυς, because there the beard doeth first flourish or breake out. The Iaw is double, the vpper and the lower, called by *Hippocrates* and *Galen* ἀνω and κατω γενυς.

The vpper Iaw is the bony part of the Face, which maketh the lower part of the orbe of the Eye and the sides, the cauity of the Nostrils, the Cheeks, the Pallat & containeth the vpper rowes of the Teeth. The diuision of the face,

This vpper Iaw is to bee considered either whole or according to his parts of which he is compounded.

In the whole Iaw wee consider his conformation and his connexion which is made by sutures. In the consideration of the partes wee will examine the bones whereof it is compounded. The conformation of the whole Iaw is diuers, broade aboue and narrow below, because of the protuberations, perforations and cauities which are therein.

The prominences or protuberations are aboue in the middle of the face where the Nose is formed, [tab.8.figure.8.ᶠ] which is peculiar onely to man, for onely a mans Nose swelleth out or standeth off from his Face. At the sides it swelleth on both handes, at the Temples to make the lower edge or verge of the Eyes and of the Cheekes [table 8. The protuberations of the vpper iaw.

fig.8 aboue r] although it alſo make the lower cauity of the eyes. Below on the outſide, wher the roots of the teeth are it buncheth circularly: [vnder A] within it maketh the anterior and greater part of the pallat which is rough, [tab.8.fig.9 t y z] and in the circumference it protuberateth for the dens or ſockets of the teeth. [fig.9 u u]

The perforations. The perforations are partly ſmall, through which the veines, arteries, and nerues are tranſmitted, as ſhall be ſaide in the Hiſtory of the particular Bones; partly great, two in the lower cauity of the eyes, as in the ſecond bone [fig.8 C] through which the rheume falleth and a ſmall Nerue vnto the noſethrilles; and in the fourth through which a little nerue runneth to the outſide of the cheekes. So alſo in the foreſide of the Plate and in the middeſt thereof one perforation which admitteth a ſmall veine and a little Artery [fig.9, z] and on the backſide of the palate two on either hand which run vnto the ſides of the noſethrils [at V]

The cauities. The Cauities are Proper and Common. Proper to the fourth bone wherein there is a den cloſed vp within the bone at the ſides of the noſethrils [fig.8 vnder x y] & the ſockets made to receiue the teeth, of which we ſhall ſpeak in the deſcriptions of the fourth bone. The Common cauity is that of the noſethrils, diſtinguiſhed by the partition and filled aboue with the ſpongy bones, which cauity both outwardly in the noſe [figu.8 OO] and inwardly in the mouth [figu.9 at qq] is alwayes open, that the ayre in expiration may returne backeward, and in ſmelling bee drawne vpwarde, and Rheume be that way euacuated.

Why the crocodiles vpper iawe is immoueable. This vpper iaw in all creatures is immooueable excepting the water Crocodile, of which, ſaith *Archangelus*, there can be no particular reaſon giuen. A common Reaſon he giueth out of *Ariſtotle* where he ſaith, that the Body is the Inſtrument of the Soule, & therefore Nature hath accommodated the body and ſo furniſhed it as it wee ſee for the behoofe of the Soule in Men, in Oxen, in Horſes, yea and in the Crocodile too, whoſe ſoule hath ſome poure or faculty to vs vnknowne, but expreſſed by the motion of the vpper Iaw; but his nether iawe is ſo vnited with the Temple-bones that it cannot at all bee mooued, becauſe it is faſtned into a boſomes, whereas the vpper is articulated on eyther ſide with a broad head. Yet *Ariſtotle* ſaith, that his vpper iaw was made mooueable to recompence the defect of his feete, becauſe they are little, and vnfit either to catch or to receiue his prey.

In a Parrat or Poppingey both iawes are mooueable, and he moueth them either one at once or both together as he liſteth. In a man the vpper iaw is immoueable, firſt, becauſe the motion thereof would haue hindred his ſight. Againe, in receiuing of Odours and inſpiration of aire the motion of the vpper iawe would haue made an interruption. Thirdly, hard meats could not haue bene ſo well broken; for as in a Mill where Corne is ground one ſtone muſt reſt immoueable the other muſt run vppon it, ſo in the grinding or breaking of meate it was neceſſary that one part which is the vpper iaw ſhould be immoueable, the other which is the lower iaw moueable.

Why a mans immoueable.

Heereto we may add, that the immobility of the vpper iaw is a beauty to the face, for if it had bene moued then it muſt neceſſarily haue bene corrugated or contracted, and ſo the elegancy and forme of the face bene deformed; whereas in the frame of mans body our Wiſe Creator had an eſpeciall reſpect to make the face beautifull, becauſe it is the image of the ſoule; wherfore a mans face is not ſet off from his head as in brute beaſts, but made ſhort and round for beauty and better forme.

Connexion. The vpper iaw is faſtned either with the bones that are about it, or with the proper bones of which it is compounded; which connexion is made by immouable commiſſure or conjunction, and that partly by ſutures or ſeames, partly by *Harmony* or *Cæmentation*. Of theſe Sutures or commiſſures ſome are common vnto the ſcull with the bones of the vpper iaw, and thoſe are fiue, of which we ſpake before in the fift chapt. Others are proper to the bones of the iaw and are nine in number, and ioyne together twelue bones of the iaw, ſome of theſe, that is, two, are in the cauity of the noſethrils, the other ſeauen are on the outſide. Againe of theſe ſeuen fiue are common to two bones of the iawe ioyning together, and two are peculiar to one bone. Of theſe in order.

The firſt inter nall ſuture. The firſt internall ſuture we meet withall in the cauity of the noſethrils, & it is common to the partition and the fift bone. His courſe is ſhort and obliquely downward. [tab 8.fig.8 vnder f] The ſecond is alſo found thereabout and is common to the partition of the noſethrils and the fourth and ſixt bones of the iaw, his courſe is ſomewhat longer and forward,

forward, but ouerthwart. [Tab.8.fig.8 ᵉ]

The first externall suture runneth obliquely to the cheeke-bone, and of it there are three parts, the first runneth through the cauities of the Temple-bones outwarde and downward to the lower side of the cheeke: the second through the foreside of the cheek vpward and inward to the middle part of the eye. [Tab. 8. fig.8 from æ vnto the lower D] The third in the cauity of the eye; it runneth backward and outward [From the lower ᴰ to ᴮ] and determineth at the second suture which is common also to the scull. This first externall suture is common to the first bone and the fourth. The first externall.

The second externall suture runneth circularly in the orbe of the eye aboue the compasse of his bone; it beginneth at the third common suture and runneth downward, then presently forward, and again from thence vpward. This suture is common to the second bone with the third on the backside, and to the fourth bone on the outwarde and lower side. [tab.8.fig.8 from V to ⁱ. from thence to C and Δ]

The third is also in the orbe of the eie, and runneth directly outward from that suture which is called the second common suture of the wedgebone, and determineth in the second suture; it is common to the third and fourth bone. [ta.6.fig.8 from ᵈ to ᶜ]

The fourth is at the outside of the nosethrils, and runneth from the third common suture directly downward throughout the length of the fift bone as far as to the gristle, and this is common to the fourth bone and the fift. [Tab.8 fig.8 from ƶ to ᵉ]

The fift is in the pallat and runneth ouerthwart through the backside therof, & it is common to the fourth bone with the sixt. [tab.8 fig.9 ᵉ ᵘ]

The sixt is in the vpper part of the nose, and runneth from the middle of the Browes, where the third common suture is, directly throughout the length of the nose, and distinguisheth the fift bone through the middest.

The seauenth is in the pallate, a line rather then a suture; so also is the sixte saith *Columbus*, it runneth directly through the whole length of the Pallate, and is verie conspicuous both vvithin and vvithout the Nosethrilles, and diuideth thorough the middest the fourth bone and the sixt. [tab.8.fig.9, ʸ ˣ] So also in the forepart of the iawe it runneth from the cauity through the middest of the *shearing*-teeth directly downward vnto the pallat, [tab.8, figu. 8 ʰ] but in Dogges, Apes, and Swine, and those creatures whose Dog-teeth are strong and hang ouer the iaw we meete, saith *Vesalius*, with two sutures or Harmonies which are not to be found in a man, and therefore they haue peculiar bones in which the Shearing-teeth are fastned.

There are also certaine Bastard Sutures, which do not quite diuide the bone but are rather lines or inscriptions and are onely founde in the fourth bone: first in the lower part of the orbe of the eye which runneth from the first perforation obliquely vnto the compasse of the eye but no further, and diuideth the fourth bone betweene the vpper seate of the first perforation and the circumference of the eye. [Tab.8.fig.8 ⁱ] Againe, in the forepart of the palat runneth a line obliquely from the second perforation of the fourth bone vnto the *Dog-teeth*. The Bastard Sutures.

This saith *Columbus* in children is very manifest, but in growne bodies there remayneth no signe or footestep thereof. Heereto opposeth *Falopius* in his Obseruations where he saith, I dissent from them who say there is a suture found attaining ouerthwart vnder the pallat to the Dog-teeth on either side, which in children should be conspicuous, but in growne bodies is obliterated. For I finde saith he, that this is a diuision or a rifte rather then a suture, because it doth not separate one bone from another nor appear on the outside: for how can it be a kind of articulation if it do not ioyne one bone with another. Moreouer, I cannot bee perswaded that this diuision, such as it is, is more conspicuous in children then in growne bodies, for I finde it very seldome obliterated and that in verie old men. Disagreemẽt betwixt *Falopius* and *Col.*

Thus farre *Falopius*. *Bauhine* addeth, that although in men it doe not diuide the Bone throughout, yet in Dogs, Apes and Hogs it doth, in which creatures it doth not only diuide the fourth bone in the palat, but also on the outside in the forepart of the iaw.

CHAP. X. *Of the Bones of the vpper Iaw.*

THE vpper iaw doth not consist of one Bone but of many, not only to make it fitter to repell iniuries, but also and especially that out of their Commissures and coniunctions might yssue Ligaments to make vp the constructi-

on or frame of the Muscles, which by that meanes are more firmly fastned

to

to their originals as to bony parts and therby made the ſtronger. Beſide, it was not fit that the vpper law ſhould be on euety ſide a like thicke or harde, or faſt or ſoft. The bones therefore of the vpper iaw are of two ſorts, Common and Proper.

The common bones of the Iaw.

The Common Bones are the VVedge and Spongy bones called alſo the ſeuenth and the eight bones of the head. From this eight bone do yſſue two ſpongy bones ſeated in the inſide of the noſe, which diſtinguiſh the vpper part into two ſides, to theſe are ioyned other two which make vp the inner orbe of the eye, which alſo wee will account, as other men do, for the third bone of the Iaw. But of theſe wee haue partly ſpoken before in the ſeuenth chapter among the bones of the Head, partly in the eight amongeſt the bones of the Noſe, and therefore we will come now vnto the proper Bones of the Iaw.

The proper bones. First.

The proper bones of the iaw which helpe to make the face are twelue. The firſt [ta. 8. figure 8. Γ r] maketh a good part of the Cheeke, the lower part of the eye to wardes the Temples, that round extuberation which *Hippocrates* calleth κύκλος προσώπου the circle of the countenance, one part of the yoake-bone, a litle of the temples and the vtter angle of the eye. The figure of it ſaith *Columbus* is diuers: *Bauhine* ſaith it is triangular, ſending forth of a broad middle three protuberations; one to the angle of the eie, another to the teeth, and a third which is moſt notable, that is, the proceſſe which maketh a part of the yoke-bone, [tab 8. fig. 9 ˣ with ʸ] and hauing a perforation or two but verie ſmall ones.

This firſt bone is ioyned to foure bones: aboue, to the forehead bone where the eye-browes end by the firſt [tab. 7. fig. 6 & 7 ᴿ] common ſuture: [tab. 8. fig. 8 ᴿ] behind, to the wedge-bone by the ſecond common ſuture: [tab. 8. figu. 8 from S to ᔓ] at the ſides, it is ioyned by his proceſſe to the proceſſe of the Temple bones by the fourth common Oblique ſuture: [tab. 8. fig. 8 ʸ] below, to the fourth Bone of the vpper iaw neere the cheeke, and in the lower part of the orbe of the eye. [tab. 8. fig. 8. from the lower D by the vpper D vnto ᔓ]

Second.

The ſecond bone [tab. 8. fig. 8 Δ] ſtandeth in the great angle of the eye neere the Noſe, and iuſt at the beginning of the angle where the hole goes into the noſethrils [t. 8. fi. 8, C] wee meete alſo with a caruncle which like a glandule receiueth the Phlegme which floweth from the Braine vnto the eye to deriue it vnto the noſethrilles that it ſhoulde not fall downe the cheekes. *Galen* alſo addeth, that Medicines which are put into the eyes, doe vſe to yſſue out of the noſethrils, whereat *Columbus* much maruelled, becauſe ſuch medicines muſt penetrate the Membrane before they can get into the noſe.

This is a ſmall bone, thin as a ſcale and tranſparant, and becauſe it hangeth but looſely, as being rather ioyned by harmony then by ſuture, to the outſide of the fourth bone, it is eaſily broken and loſt, and therefore we rarely meete with it in the ſculles digged out of the earth, for being and in a moyſt place it eaſily putrifieth; but in thoſe ſculs that are boiled it is eaſily preſerued. It is ioyned to three bones: aboue, to the forehead bone by the third common ſuture: [tab. 8. fig. 8 nere v] behind, to the third bone of the iaw by the ſecond externall ſuture; [from V to V] before and below to the fourth of the iawe by the ſame ſuture: [from C toward x] ſomtimes alſo it is ioyned vnto the ſpongy-bones of the Noſe. And this is the place where thoſe Apoſtemations are which the Græcians call ἀιγίλωπας, which if they be neglected do penetrate to the mouth, and do end into *weeping Fiſtulaes*. This bone alſo hath ſome perforations; aboue ſome ſmall ones which are common; one alſo very notable which is cõmon to it with the fourth bone, [t. 8. f. 8 C] which runneth out of the inner angle of the eye directly downward into the cauity of the Noſethrils: the vſe of it is to tranſmit a ſmal portion of the leſſer roote, commonly ſo called, of the third coniugation, and alſo Rheume or Phlegme.

Aegilops.

Weeping Fiſtulaes.

The third Bone which we ſaide was the fourth part of the Spongy-bone, [tab. 8. f. 8 Θ] but is by moſt made the third of the vpper iaw, is ſeated in the inner ſide of the eye, and within is continuall with the fungous bones of the Noſethrils. This is broader then the ſecond, quadrangular but ſomwhat round, thin & tranſparant like the ſcale of a fiſh; with out ſmooth, within rugged and vnequall, becauſe of the ſcales that cleaue vnto it: & if you breake it, within you ſhall finde large cauities filled with aire.

Third.

It is ioyned to foure bones. Aboue to the forehead bone by the third common ſuture, & there is a good length off the ſuture between them [t. 8. fig 8 from ᵀ toward ᵛ] Behind, to the wedge-bone by the ſame ſuture, but the length of it is leſſer. Before, with the ſecond Bone of the iaw by the ſecond ſuture. [from V to ᶜ] Belowe, to the fourth bone of the iaw by the third ſuture. [from ᶜ to ᵇ]

The

The fourth bone [tab.8.fig.8.AA] maketh for the most part the forepart of the nose-thrils and of the mouth, into which al the vpper Teeth are infixed, also the sides and lower part of the pallat and of the holes of the nostrilles; yea and beside the lower part of the orbe of the eye toward the Nose. *Galen* calleth it *Os mala* the Cheek bone, and he saith it deserueth well to be called by the name of the whole, the vpper Iaw. It is much larger then any other of the bones, and is circumscribed with many sutures, for it abutteth vpon seauenteene bones if you reckon the Teeth. Aboue neare the Nose it is ioyned to the forehead bone (yet but a little way) by the third common suture. [ta.8.fig.8.$^{x\ x}$] Below to the wedge bone by the second common suture [ta.8.fig.8.from ^{p} to ^{n} fig.9.from ^{d} to ^{e}] where also the vpper part of the wedge bone and the iaw doe yawne into the orbe of the Eye. The fourth. His connexions.

It is also ioyned with other bones of the vpper iaw: as to the first by the first oblique suture [tab.7.fig.6.^{ab}] in the Cheeke, the orbe of the Eye and the cauities of the Temples. Before to the second in the inner angle of the eye by the second suture. [ta.8,fig,8, from C toward X] Behinde to the third by the third suture. [from ^{b} to ^{c}] On the outside to the fift bone in the top of the Nose by the fourth suture: [$^{c\ y}$] to the sixt in the Pallat by the fift suture; [ta,8,fig.9.^{tu}] and finally to his owne companion by the seauenth suture, or rather by a line, partly in the forepart of the iaw [tab.8.figu.8.^{h}] where the furrow is of the vpper Lip, partly in the pallat [tab.8.fig.9.^{xy}] Into this fourth bone also are the vpper Teeth fastened by *Gomphosis* or way of *Mortize*, and it is vnited vnto the Gristles of the Nose.

It hath also perforations and dennes. The perforations are Common and Proper: one Common which is very small toward the inner angle of the Eye. The Proper are two in the lower part of the Eye, on each side one, which is onely couered with a bony scale, and runeth from the lower part of the Eye outward: his vse is to transmit a surcle of the lesser roote, commonly so called, of the third coniugation of sinnewes out of the orbe of the eye into the Face. [ta.8.fig.8.at ^{x}] 3. Perforations.

The third hole is in the Pallate at the backepart of the *Shearing* or shredding Teeth, where both bones of the iaw do meete. [ta.8.fig.9.^{z}] It runneth out of the Pallat into the capacity of the Nostrilles, and transmitteth a small veine and a small artery vnto the nose; and at the sides hereof there appeareth a suture in young children.

The dennes or cauities of this fourth bone are of two sorts; of the first is one on each side at the lower sides of the cauity of the nostrilles vnder the orbe of the Eye. It is a great cauity, and so large sometimes that in it a man may lay his thumbe end: and therefore it may well be likened to those hollow images made of molten waxe: yet is it couered with an attenuated bone, blowne vp as it were round, [ta.8.fig.8.vnder ^{x} ^] which was made partly because of the leuity of the bones, which in this place stoode in neede to bee thicke by reason of the situation of the eyes, partly because it is most fitte to forme the voyce, so sayth *Vesalius*. Cauities.

This cauity is not to be found in young children, but is made as they grow, and is inuested with a very fine coate, it is also found full of mucous or slimy phlegme, or marrow saith *Archangelus*, whereby the bones that containe the Teeth and all the vpper Teeth also are nourished. Of the second kinde of dennes of this fourth bone, are the sockets or mortizes of the Teeth which are insculped in the lower brinke thereof, in which the teeth are fastned. [ta.8.fig.8.vnder ^{h}.]

The fift bone of the vpper Iaw, [t.8.fig.8.$^{x\ x}$] which with his companion maketh the bony prominence of the Nose, is a small bone and almost quadrangular, but somewhat long, yet shorter by farre in a man then either in Dogges or in Apes. It is a hard, solid, broade and thinne bone hauing smal common perforations in it. It is ioyned aboue to the forehead bone by the third common suture; [tab.8.fig.8.^{yz}] againe in the sides to the first bone of the iaw on either hand, and outward to the fourth bone by the third proper suture, [fig8, from ^{e} to ^{x}] and in the middle it is ioyned to his companion by the sixt suture [fig 8. from ^{z} to ^{f}] which is not much vnlike a harmony, and runneth directly from the suture of the forehead throughout the length of the bones of the Nose. Below it hath no suture but is rough and vnequall that the gristles of the Nose might take better hold vpon it. On the inside where these two bones are ioyned, they adhere to the bony partition vnder them, and that cleaueth to the spongy bone. The fift.

The sixt and last bone of the vpper Iaw (for you must reckon euery one of these dou- The si[xt]

ble,

ble, one on one ſide, another on another) [ta.8.fi.9, n] is placed at the end of the pallate, where the noſethrils do determine into the chops and maketh together with his companion the backpart of the circumference of the noſethrils and the pallat. It is a broad bone thin and ſolid, and in the end where it is rough it reſembleth a ſemi-circle. [tab.8.fig.9 a. boue q] It is ioyned behinde, to the wedge-bone at his wingy proceſſes: belowe, and on the outſide by a part [q] of the ſecond common ſuture. On the inſide to the partition of the noſethrils by the ſecond externall ſuture: [tab.8.fig.8 s] againe, to the fourth Bone of the iaw by the fift tranſuerſe ſuture; [fig.9 t] and finally, to his companion in the backe-part in the pallate by the fixte ſuture running along the length of the pallat [tab.8.figu.9. from *t* to *x*]

The perforations.

It hath two perforations on either ſide, one large which runneth vpward and backward to the ninth common hole of the wedge-bone, [tab.8.fig.9. a little below *r*] the other ſmall, which ſometime determineth into the former, ſomtime into the ſecond common ſuture. [aboue q at r]

CHAP. XI. *Of the lower Iaw.*

The Lower Iaw

THe lower Iaw, which the interpreter of *Halliabba* calleth *Fauces* [tab.11.fig. 1 & 2] maketh the lower part of the capacity of the mouth, into it the teeth are infixed and it is articulated to the ſcull. In men it is mooueable and by it they chew their meate for, becauſe the teeth muſt grind and cut that which is eaten, it was neceſſary that the vpper teeth ſhould depart from the lower and returne againe vnto them. And becauſe in the deſcent it needed no ſtrength, but in the aſcent very great ſtrength, as well to lift vp the weight of the bone as to breake the meate, therefore it is depreſſed by weake muſcles, but lifted vp by exceeding ſtronge as we haue ſhewed before in the 10 booke. This iaw in a man is ſhorter then in anie other creature proportionably. It is almoſt orbicular becauſe of the roundnes of his face wherin is his beauty. In other creatures, ſaith *Galen* (excepting an Ape, whoſe face and hands are much like vnto a mans) the iawes are long and prominent, becauſe they vſe them inſtead of hands, and becauſe they were to be enclined to the earth to gather their foode.

His Figure.

The figure of it is like a bow, the belly hollow for lightneſſe, and that it might not offend the muſcles which moue it. Before, in the top of the chin it is broade and thicke, in other creatures it is narrow and prominent. Behinde it is parted, partly that the paſſage of the meate ſhould not be hindred, partly that it might more commodiouſly for motion be articulated to the ſcull on either ſide.

Proceſſes.

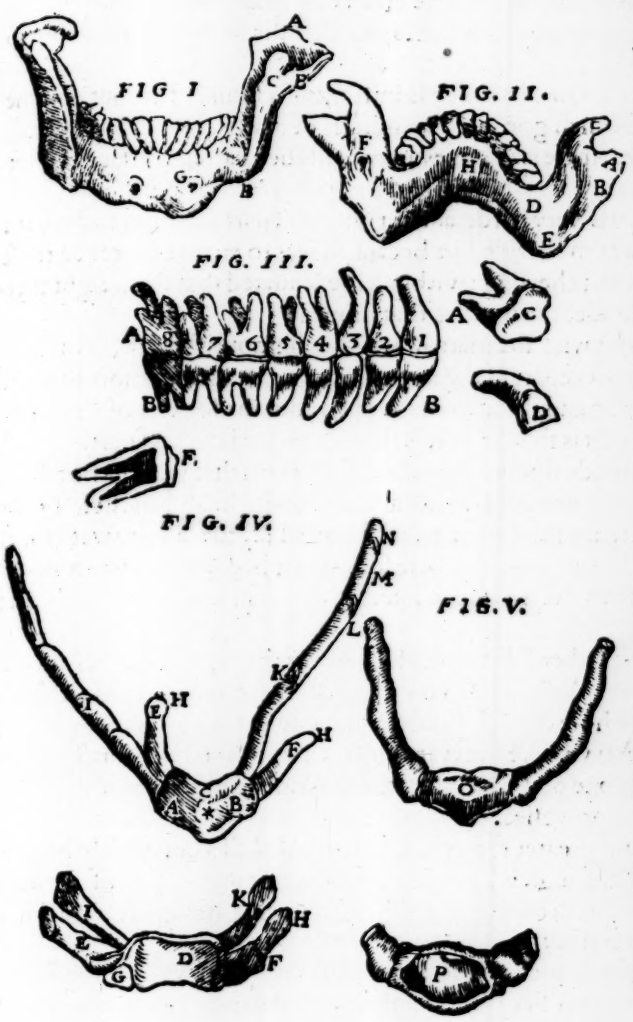
For it hath on the backſide on either hand two proceſſes (ſome call them Hornes) which run vpward. One turned backward, [Tab.11.fig.1 & 2 C] broad and thin, ending into a cone or point called κορώνη which receiueth the tendon of the temporall Muſcle; for that tendon compaſſeth it round about, and is very ſtrongly implanted thereinto; & hence haply it was, that *Hippocrates* ſaith, the luxation of the lower iawe is moſt-what mortall, becauſe of the diſtention and alteration of the temporall muſcle.

The other and the backer proceſſe is called κονδυλοειδὴς and is like a knot. It runneth backward, hauing a long prominent head and tranſuerſe, [fig.1 & 2 A] whereunder there is a notable necke. [B] By this head it is articulated into a cauity on either ſide anſwereable thereto inſculped in the Temple-bone, which articulation is made betwixt the root of the yoake-bone and the Hole of Hearing. By this articulation the iaw is mooued vpward to the ſcull, downward alſo and ſomewhat to the ſides: ouer the heade, as alſo ouer the ſinus there is a griſtle couering them like a cruſt.

But beſides this which is common to all ioyntes, there is another griſtle repoſed betwixt the boſome and the head which is ſmooth, thin and ſoft, doing not onely the office of a Ligament to conteine the proceſſe within his cauity, but alſo it maketh the motion of the ioynt more glibbe and ſlipping. Moreouer, togither with the other griſtles in the ſtrong and perpetuall motions of the iaw it keepeth the bones from breaking, at leſt from wearing one againſt another.

This ioynt alſo of the lower iaw with the Temple-bones is couered with a common Membranous Ligament. On the backſide on either hand where it ſhooteth out his proceſſes [fig.1 and 2 EE] it is exaſperated with ſmall protuberations like litle riſing hillocks eſpecially where it is broadeſt behinde and below. Before and on the inſide in the middle of the chin there riſeth a bunch vp, [fig.2 *x*] made for the ſtronger inſertion of the proper

TABVLA XI.



Tab. 11. sheweth the lower iaw together with the teeth in the first and second figures. The third figure sheweth the Teeth by themselues.

A. The head of the iaw wher it is articulated vnto the Temple-bones.
B. The necke of the Head.
C. The processe into which the Temporall Muscle is inserted.
D. A Bosome or cauity giuing way to the third muscle of the lower iaw
E, A roughnesse into which is inserted the muscle called *Massorius*.
F. The inner perforation.
G. The vtter perforation.
H. Asperities into which the Muscles are implanted.

Third Figure.

AA. Eight vpper Teeth.
BB. Eight lower teeth.
C. The basis or bottome of a *grinding*-tooth called *Molaris*.
D. The basis or bottome of a *shearing-tooth* called *Incisorius*.
E. The Cauitie that is in the grinding teeth when they are broken.

per muscles by which it is led downward, as also to giue a more commodious originall to some muscles of the tongue; for where the place is rough and vnequal there the muscles will cleaue the faster. In like manner also is it exasperated on the outside at the toppe of the chin, [tab. 11. figu. 1 vnder °] that the Muscles of the lower lippe might better arise therefrom.

At the sides of the processes it hath superficiary or shallowe bosomes, yet so that it is more hollowed on the inside then on the outside. VVithout on each side one, and that large; [fig. 1 betwixt ᵇᶜ] within two distinguished by a certaine knot. [fig, 2 neere ᴰ ᴱ] The anterior at the roots of the teeth was made to giue way to the gummes, the posterior and the larger affordeth a seate vnto the muscle that *lurketh in the mouth*, that his thickenesse and bulke should not fill vp the narrownesse of the chops. The Bosomes.

It is compounded of two bones, for in infants the two bones are very manifest, ioyned together in the middle of the chin by a plentifull gristle, so that in some bodies at seuen yeares of age, the markes or footsteps thereof doe remaine, but in grown bodies the gristle is chaunged into the nature of a bone, and those two bones are so strictly vnited, that there doth not appeare so much as any shew of a line betwixt them, neyther can they be separated by boyling, by putrifaction, or by any strength, which is the reason why *Vesalius* concludeth it to be but one bone. For, saith he, although in young children it be formed of two bones vnited together, yet we cannot simply say that the lower iaw consisteth of two bones, vnlesse we will also say, that the Nowle-bone, the *vertebra* or rack-bones and the bones that are ioyned vnto the sides of the Holy-bone bee made of many bones, for in children euen these are built vp of many bones. The composition of it. *Vesalius.*

Falopius

Falopius makes answere, if *Vesalius* say wee may not make denomination from imperfect partes, then certainly all Anatomistes haue erred who speake so much of Appendances: for they are found onely in imperfect bones, not after the body is growne: but to proceede.

The Line which we see in the iaw of a childe is insteade of a suture, that out of it the Ligaments might be produced which goe into the muscles of that place. In Dogs, Oxen, Asses, and many other creatures, these two bones may easily bee parted without coction or any great violence.

Why it is hard. The bone of the lower iaw is very hard, and for the most part solide to make it the stronger; not because it alone was moueable, but because it was to endure diuers & those very violent motions in biting and chewing: within it is excauated that the weight ther. of should not be offensiue or hinder the muscles that moue it.

Cauities. It hath also cauities to contayne the marrow which is his nourishment, which are not exsculped or grauen in the backepart of the iaw as in bruite beasts, but more forward toward the Region of the Chinne and the sides of the iaw vnder the sockets of the teeth, and therefore about these places it is thicker, as it is thinner toward the backpart.

For that the lower iaw is made thicker by reason of the teeth that were to be fastned therein hence it appeareth, because in old bodies and those who haue lost their Teeth, or where the sockets of the teeth are grown vp; in such bodies I say the iaw groweth much thinner and narrower from below vpward. These sockets, or beds, or mortize holes, or what you list to call them, wherein the Teeth are infixed, are engrauen in the embowed compasse of the iaw.

Perforations. Perforations also it hath on either side tvvo, vvhich runne through the iavv like a Canale or pipe; for put a bristle into the hole of a iavv vvhen it is drye on the inside and you shall easily thrust it through the hole on the outside, and if you breake the iavv in sunder you shall finde that the vvay betvvixt the outvvard and invvard hole is continuall and formed round like a canale. The one of these perforations is inner and backer at the internall bosome not farre from the processes.

It is on each side one, and greater then the other, vnequal also or rough beginning like a scale, [tab. 11. fig. 2] and through it a portion of the third coniugation of nerues is dispersed vnto the roots of the Teeth (together vvith a small veine and artery) vvhich sendeth small surcles to the teeth and to the iaw.

The other perforation is small and round, grauen or thrilled without at the sides of the chinne, [ta. 11. fig. 1. at c on either side] and by it the foresaid nerues being now within, doe againe returne out of the iaw outward into the lower lip, and this second perforation is far lesser then the first.

CHAP. XII. *Of the Sockets of the Teeth.*

The sockets of the teeth. IN the circumference or margent of both the Iawes, which place *Galen* called φάτνια, we meete with certaine cauities or hollow places which the Latines call *Alueoli* or *Locelli*. They are digged deepe that the Teeth like so many nayles might be firmlier fastned in them by *Gomphosis* or by way of Mortize; and therefore the rootes of the teeth are made iust fitte and answerable to the holes of the Iaw, for if they had bin broader the composition would haue beene too dissolute, and if they had beene too narrow the rootes of the teeth would not haue attayned to their bottomes, but being fitte as they are they are very firmely conteined. The number of these sockets can hardly be assigned, because they are sometimes single, sometimes double, sometimes treble, according to the variety of the roots of the Teeth.

Moreouer, although they be bony, yet they appeare to be almost like wax, and may well be compared to the holes of a hony combe which are often obliterated and often againe renued: for when a Tooth is drawne, vnlesse a new one grow vp, the hole is so constringed that there remayneth no print thereof: yea if a Tooth fall out and a newe one doe rise vp in his roome, the former socket is obliterated and a newe one grauen for the new Tooth.

The Formatiue faculty remaines in the teeth. Hence *Falopius* concludeth, that the liuely and quickning Formatiue faculty remaineth in the Teeth vnto the period of a mans life, for by it they encrease and receiue their forme. So in the Cheekes and the Iaw when those Teeth which wee cal *Genuini dentes* or *dentes sapientiæ* doe shoote out, haply about seauenty yeares of age, yet euen then new

soc-

ſockets are made for them. Againe at fourescore when the teeth fall, the ſockets grow vp and the iaw in that part is ſo compreſſed that the bone on euery ſide cleaueth together, & at length is vnited. For the ſockets are not onely filled with a bony ſubſtance and rammed vp, but each partition growing to other do make a ſharpe edge which in olde men ſerueth in ſtead of teeth, if not to cut yet ſomewhat to breake and chew their meat. And ſo much of the Sockets, now we come to the Teeth themſelues.

CHAP. XIII. *Of the name, definition, figure, magnitude, number, ſite and articulation of the Teeth.*

THE Teeth are called in Greeke ὀδόντες, as it were ἐδόντες of ἔδω, which ſignifieth to eate. In like manner the Latines call them *Dentes quaſi edentes* of eating. They are the hardeſt of all the bones, hollow within, hauing ſmall veynes, arteries, and nerues; articulated to the ſockets or deus of their owne iaw *Per Gompheſin*, or by way of mortize, faſtened with membranes, & fleſh, or ligaments, & prim arily created for the comminution or mitigation or chewing of the meate. Their names.

That they are bones ſome men do deny, firſt becauſe bones are inſenſible the teeth ſenſible. Secondly, becauſe the bones haue certaine limits of auction or increaſe, neyther do they euer grow againe if they periſh, but in teeth it is quite contrary. Thirdly, becauſe they are harder then other bones. Fourthly, becauſe bones expoſed to the ayre do grow blacke, whereas the teeth keepe their whiteneſſe. Fiftly, they ſay, that *Hippocrates* in the 18 Aphoriſme of the fift ſection diſtinguiſheth them from bones where he ſaith, that cold things are enemies to the teeth, to the bones, and to the nerues. Finally, ſay they, there is a ſtone that will conſume fleſh called therefore *Sarcophagus*, which within forty dayes will deuoure the whole body except the teeth. If therefore the teeth were of the nature of bones they alſo would be conſumed. Arguments that teeth are no bones,

We anſwere to the firſt, that ſenſe is not of the nature of a bone. To the ſeconde, that they grow becauſe in attrition they are worne. To the third, that *more or leſſe* do not change the ſpecies or kind, otherwiſe the ſpongy bones ſhold be no bones. To the fourth, that they are accuſtomed to the outward aer and haue no perioſtion on them, and the Philoſopher ſaith, that that which is accuſtomable maketh no impreſsion or alteration. To the fift, that is, to *Hippocrates* authority we ſay, that the bones and the teeth are affected by cold diuerſly; the bones onely by ſuffering, the teeth not onely by ſuffering but alſo by ſenſation. To the ſixt, firſt we may ſafely doubt of the experience; ſecondly, we may ſay that the Teeth are not conſumed becauſe they are harder then other bones. Anſwered.

It remaineth therefore according to *Hippocrates*, *Ariſtotle*, and *Galen*, that the Teeth are bones, for ſaith *Galen* they cannot be referred to any other ſimilar part, and therfore he placeth the teeth vnder the common *Genus* of the bones, and the rather becauſe the qualities of their matter do agree, as hardneſſe, ſolidity, ſmoothnes, whiteneſſe, &c. yet there are ſome differences betwixt them and other bones. For among all the bones none but theſe haue any exquiſite ſence becauſe the teeth alone do admit nerues into their cauitie.

The teeth alone do increaſe as the life increaſeth, that without any detriment they might performe their offices: for being worne in the chewing of meates they are increaſed againe, but onely ſo much as they are worne away, otherwiſe they would ſoone fayle. The other bones haue no ſence or but obſcure, neither do they increaſe alwayes but when they come vnto their ſtate or perfection they make a ſtay becauſe they are not changed in the performance of their functions.

They differ alſo from bones becauſe they are naked hauing no perioſtion without the, for then they would be payned in the wearing; hence it was that *Ariſtotle* doth oftentimes not number the teeth among the bones, but ſometimes ſaith they are bony, ſomtimes that they reſemble the nature of bones. And truly in their hardneſſe, faſtneſſe, or ſolidity they doe exceed other bones, yea they are little ſofter then ſtones themſelues, if they bee not allout ſo hard eſpecially about their extremities. Some are ſtony like a milſtone, others are ſharpe like the ſteeld edge of a knife. They were made very hard that they might not weare ſo ſoone or be broken in the chawing or breaking of hard things, for they are not lined eyther with fatte or griſtles as other ioynts are to hinder attrition. The teeth therefore do breake bones, reſiſt the edge of ſteele, neyther can they eaſily as other parts How they differ from bones. Why they are hard & how.

of the body be burnt with fire. *Hippocrates* in his booke *de Carnibus* aſcribeth the cauſe of their hardneſſe to the quality of the matter out of which they are ingendered, for hee writeth that out of the bones of the head and the iawes there is an increaſe of a glutinous matter. In that glutinous matter the fatty part falleth downe into the ſockets of the gums where it is dryed and burnt with the heate, and ſo the teeth are made harder then other bones becauſe there is no cold remaining in them.

Their ſurface

Their outward ſurface is by nature white, ſmooth and poliſhed, but in age for want of care or by diſeaſe they become liuid or duskiſh. There groweth alſo vnto them a hard ſcaly matter by which as alſo by corruption they become rugged and vnequall, yet ſayeth the Philoſopher a horſes teeth become whiter as he becomes older.

Forme.

Their forme is before ſomwhat round, behind more plaine; where they are ioyned one to another they are euen, and in their extremities ſomtimes thinne, ſomtimes ſharpe, ſomtimes plaine, but alwayes vnequall,

Difference.

They differ among themſelues in figure, magnitude, and number. Their figure in man differeth according to the difference of their vſe in chewing. In fiſhes they are only acute or ſharpe. In thoſe creatures that chew the cudde they are of a double forme; ſome *Grinders* and ſome *Shearers*. In men according to the three ſpeciall diuiſions of meates there are three kinds of teeth, *Shreaders* or *Shearers* called *Inciſores*, *Dog*-teeth called *Canini* and *Grinders* called *Molares*.

Againe mens teeth do not ſtand out of their formes as a Boares tuske, but are concluded or ſhut within the mouth; neyther are they ſet like the teeth of a Saw as it is in dogs, for their teeth are giuen them in ſtead of weapons.

Magnitude.

The teeth of a man are much leſſe then the teeth of many other creatures leſſe then he, for his mouth is much leſſe: for according to the magnitude of the mouth is the ſtrength of the teeth which conſiſteth in their figure, hardneſſe, and quantity; yea mens teeth compared among themſelues are not equall but ſome greater ſome leſſer, for the grinding teeth are greater then the reſt.

Number.

The number of the teeth is not in all men one and the ſame, for ſome haue more, ſome haue fewer, yet the more the better, for ſuch, ſaith *Hippocrates* in the ſixt ſection of the ſecond *Epidemion*, are long liued, whereas thoſe that haue few teeth are but ſhort liued as *Ariſtotle* ſaith in the 3 chapter of his 2 booke *de hiſtoria Animalium*. The reaſon is, becauſe the paucity and rarity of the teeth is an argument eyther of the want of ſpermatical matter or of the weakneſſe of the formatiue faculty.

Diuers rowes of teeth in ſome men.

Againe, thoſe that haue but few teeth do not chew their meate ſo throughly, nor prepare it ſo well for the ſtomacke. So that the Chylus is not ſo well concocted, and by conſequence the bloud not ſo pure; for the ſecond concoction which is in the veynes of the Liuer doth not amend the error of the firſt concoction which is made in the ſtomack. Stories make mention of ſome men who haue had but one tooth in their vpper iaw, and therevpon haue ſome bin cald μονόδοντες, as *Euripheus* the *Cyrenian*, *Euriptolimus* of *Cyprus* and *Pirhus* the King of the *Epirots*. Some in ſtead of teeth haue one continuall bone, ſuch was the ſonne of *Pruſias* King of the *Bythinians*. Some haue had a double row of Teeth, as *Dripetinus* the ſonne of King *Mithridates*, *Trimarchus* of *Cyprus*. Some haue had 3 rowes as *Hercules*, for ſo *Cælius Rhodiginus* reporteth in the third chap. of his fourth booke. But for the moſt part there is but one row which is called φραγμὸς, *Septum* the hedge, becauſe it hedgeth in the tongue. In both iawes there are in growne bodies 32 Teeth, 16 in each iaw, in ſome men 30, ſixteene in the vpper iaw and 14 in the neather; in ſome 28, which is the leaſt number, and then the foure laſt are wanting, for they doe not breake out in all men nor at the ſame time, ſomtime lying imperfect within their ſockets; ſometimes not formed at all by Nature.

Why many teeth.

And truly the grinding Teeth are the cauſe why Authors do not agree in the number of the teeth, for the nũber of theſe *Grinders* is often changed, the *Shearers* & the *Dog*-teeth in man very ſeldome. Theſe Grinders are ſomtimes fiue in a ſide, ſomtimes foure, ſomtimes foure on the left hand and fiue on the right, or on the contrary; or elſe four below and fiue aboue, which variety is made by thoſe Teeth which wee call *Genuini*. The Teeth were made many not one, that they might do ſeuerall offices in cutting, breaking, and chewing the meate; againe, that when one is payned or periſhed eyther by force or by corruption the affection ſhould not become common to them all.

A mans Teeth are ſet in both parts of his mouth in the vtter compaſſe of both the iawes;

Fiſhes

Fiſhes haue their Teeth in their Pallate and their tongue: Crabs in their ſtomacke. *Alexander Benedictus* witneſſeth that in a mans pallat ſometimes Teeth haue been ingendered, and *Euſtachius* teſtifieth the ſame thing from his owne experience in a woman of *Rome*. Thoſe creatures that chew the Cud haue their lower gang of Teeth whole, which reacheth euen to their Lippe, ſo diſpoſed and ſo equally ranked, that ſayth *Galen*, *Nature is much to be commended for ſo ordering the dance*, ſo he cals their rank or courſe.

The Teeth therefore are ſtreight, inclining to neither part, before are the *ſhearers*; called *Inciſores*, next to them the Dog-teeth called *Canini*, and then follow the *Grinders* or the *Molares* which are the hindmoſt, yet ſo that they are all diſioyned with a decent and conuenable diſtance, which the Grecians call *ἔυρυθμον*, for they are ſet cloſe one to another, and touch at the top, leaſt that which is chewed ſhould remaine in the ſpaces betwixt the and there putrifie. Their order.

The rootes of the Teeth doe enter into the holes or ſockets of the iawes, to which they are ſo fitted, that a nayle ſticketh not faſter in a poſt then they do in their proper places, euery tooth being compaſſed with ſlender proceſſes of the iawes which hould them faſt that they fall not out or be ſhaken.

Euery Tooth alſo ſayth *Galen* hath a nerue, and that nerue helps to eſtabliſh it, for when the nerue is looſened with too much moyſture, the Tooth becomes prominent and moueable: beſide they are very ſtrongly tyed by Ligaments which paſſe betwixt their rootes and the bottom of their ſockets. The Gummes alſo doe eſtabliſh the teeth very much, faſtning about them very exactly; and this *Commiſſure* of the Gums and the colligation of the iawes, *Rufus* cals *habena* or the bridle. In a word the Teeth are vnited by the interpoſition of nerues, membranes and fleſh. The nerue is inſerted into the cauity and ſo the Teeth may be ſaid to be ioyned by *Synneuroſis*. The fibres of the membranes do cleaue to the rootes of the Teeth: the fleſh compaſſeth them about, which being eaten away, they eyther grow looſe or fall our, and ſo they are ioyned by *Syſarcoſis*. Their compoſition.

Hence we may gather that the articulation of the teeth is by *Gomphoſis* or by *mortize* which is a kind of coarticulation, and yet *Galen* doubteth hereof and ſaith, that their compoſition commeth neare to a Coalition: neare; it may be, but indeed they are coarticulated, which may be prooued, becauſe when for want of nouriſhment they grow drye and begin to wither, then their coniunction is not ſo ſtedfaſt but looſe and vncertaine, which hapneth alſo when the nerue vnder them is ouer moyſt. Finally, their rootes are ſimple, double, treble and fourfould. Is by way of mortize.

CHAP. XIIII. *Of the Shearers and Dog-teeth.*

WE ſayd before that according to the three kinds of diuiſions of Meats, there are alſo in men three kindes of Teeth called *Inciſorij*, *Canins* and *Molares*. *Inciſorij* we cal the *ſhearers* or the *ſhreaders*; [t. 11. fig. 3.b 1.2.] they are ſeated in the forepart of the iawe, and becauſe they are the firſt, they are called by *Hippocrates* and *Ariſtotle* *πρόσθιοι*, *primores*. 3 kindes of teeth. Both in viewe and generation.

They are ſharp edged like a knife and broad alſo the better to deuide that that comes betwixt them, and are therefore called *τομεῖς*. Sometimes they ſheare a thing aſunder as a paire of pinſons doth a wire, and that is when the lower teeth are vrged, not againſt the ends of the vpper, but higher toward their bodies. And becauſe theſe Teeth in laughter diſcouered, therefore the Grecians call them *γελάσινοι*.

Theſe *Shearers* are for the moſt part foure, and thoſe two that are next the *Dog teeth* are leſſe then the other, and ſhorter then the *Dog-teeth*. [ta. 11. fig. 3. char. 2.] *Gorreus* ſayth that ſome men in ſtead of theſe foure, either aboue or below haue onely two, but thoſe ſo broade that they take vp the roome and performe the vſe of foure. Some againe in ſtead of foure *ſhearers* haue ſixe, eight, or more placed without any order, ſome of them being right, others crooking outward to the Lip, others inward into the mouth, which are ſo offenſiue both in chewing and in pronunciation, that we are conſtrained ſomtimes to draw them, ſometimes burne them, ſometimes to file them. *Bauhine* maketh mention of a Doctor of Diuinity, whoſe two foreteeth in the lower iaw were double, for when the two vtter were almoſt conſumed about the fortith yeare of his age two other grewe vp within them. The part of theſe Teeth which ſtandeth without the Gummes is narrower betwixt the Baſis and the ſides, but before and behind thicker, growing thinne and broad by degrees vnto the extremity: eſpecially it is ſo in the vpper two which are called *duales* and Are foure.

Palæ, because they are very like vnto a pale: the superficies is on the outside some-what gibbous, and againe a little hollow on the inside. The other part of these teeth which is infixed in the Iaw is toward the side flatted or compressed and endeth in a sharp point; for their roote is but single; yet greater for the most part, at least as great as any the roots of the great teeth: hence it is, that they easily fall out, especially those in the vpper iawe. In the extremities of these Teeth when men are growne to some age, there is either no perforation at all, or if it be it is wonderous obscure.

Dog-teeth. Next to these are the Dog-teeth called *Canini*, [Tab. 1 n. fig. 3. char. 3] by *Aristotle & Galen κυνόδοντες*, not so much for their figure, or because they stand out of the gummes as Dogs teeth do, as for their vse; for in dogs after the shreading teeth there are two kindes of sharpe teeth; Some standing outward, others of a triangular forme. But a mans dog-

2 in each iaw. teeth differeth from them both. They are onely two in each iaw, because a man is a mild and ciuill creature, whose strength consisteth more in wisedom then in fortitude of bodye, and therefore is not full of Dog-teeth as other furious and rauening creatures are; for to breake that which is hard two were sufficient. These go betweene the sharpe teeth and the plaine, the Shearers and the Grinders, and below at the gummes are broad and thicke, aboue sharpe and somewhat prominent beyond the course or order of the rest of the teeth. From the Shearers herein they differ, because they are thicker & their head somewhat narrower but not so sharpe. They are also harder, that if any thing by chance do come betwixt the teeth which the shearers cannot diuide, these may breake it; for the

Their rootes. shredders were made to cut meate short, and these to breake that which is hard. Their roots as those of the shearers are but single yet infixed deeper, stronger also and lesse pressed or narrowe before then behinde. These rootes are longer then the single roots of the rest of the teeth, yet so that the vpper are sharper and longer then the lower. These they call the Eye-teeth, not that they are so produced that they touch almost the lower circumference of the eye, for they do not go aboue the lower end of the wings of

Eye teeth. the nose, but because a portion of the Nerue which mooueth the eyes is deriued vnto them; and hence it is that it is commonly and truly said, that to draw the eye-teeth is not without danger.

CHAP. XV. *Of the Grinding Teeth.*

The Grinders THE great Teeth the Grecians call μύλας or μύλοι *Molares*, because by them the meate is broken as corne is broken vppon a Mill. They are seated in the inner part of the mouth and hidden by the cheekes: the reason of this

The Forme. position is, least the meat already shred or broken and by the tongue rowled vnto these Teeth to be further ground should fall out of the mouth. In their vse therefore and likewise in their forme they are like vnto a Corne-quern, vnequal, rough, hard, broad and great: Rough and vnequall, for so they are more fit for comminution, and that is the reason why Millers when their stones are growne smooth do pick them anew. But these Teeth in olde men by long attrition do becom equall and smooth and by reason of their perpetuall vse, are more sooner broken and eaten out then the rest.

VVherefore that part of these grinders which standeth without the gum is foursquare, and that square more perfect in the 3 hinder teeth: and though their tops are very large insomuch as *Ruffus* in the eight chapter of his first Book calleth them τραπέζας *Tables*, yet they are not smooth, but euery one, saith *Eustachius*, hath a pit one or two in the midst: whence it commeth to passe that their extreame or outward partes are somewhat high. Those two that are next the Dog-teeth are heightned on the inside and on the out-side, yet the first especially in the lower iaw doth sometime want his inwarde eminence: the third protuberateth or swelleth vp in foure corners: the fourth and the fifte for the most part haue two eminences on the outside, on the inside but one. These cauities and protuberations meeting iust one with another do hold the meate faster that it fals not so easily from betwixt them.

They are the hardest, saith *Vesalius*, of all the bones, that they might not so easily weare away; broad also and plaine the better to leuigate the meate that is already shorne and broken by the other teeth; for it was not fit that a man should swallow his meat before it were perfectly ground: beside being so ground, the heat & moisture of the mouth assisting, there is made in the mouth a rude inchoation or beginning of concoction.

They

They are called alſo γομφίοι, not becauſe their inſertion is by way of mortize, for that is common vnto all the Teeth, but ἀπὸ τῆς γομφιάσεως, that is from the rough ſuperficies of a Mill-ſtone, whoſe figure and vſe the vpper partes of theſe grinding Teeth doe elegantly imitate. In Magnitude they differ, for the middlemoſt are the greateſt, & thoſe on each ſide leſſer. The third is the greateſt of all in Men, in Apes the fourth and the fift; for it was not fit that the internall capacity of the mouth which groweth narrow as the anterior part doth, ſhould haue teeth ſo great as the middle where it is broadeſt of all. Sometimes to the fourth or the fift (but in the vpper iaw rather then the lower) there is adioyned as it were a halfe tooth, for Nature contending to make more grinders, is hindred by the narrowneſſe of the place, and therefore is conſtrained to ioyne them together. Magnitude.

Their Number is commonly in the vpper and lower Iawes on each ſide fiue, that is in all twenty. The reaſon why there are more grinders then ſhearers is, becauſe Nature doth vſe according to the largeneſſe or narrowneſſe of the fiſſure of the mouth to allow creatures more or fewer of this kinde. Man whoſe mouth is verie narrow, & whoſe teeth were eſpecially giuen him to chew his meate, hath therefore more grinders then ſhearers or dogteeth: on the contrary in rauenous creatures there are more *ſhearers* then *grinders*, becauſe they vſe them as weapons. Hence it is, that in men there is little difference in the number of their Shearing or Dog-teeth, but of Grinders there is great variety: ſometimes fiue, ſometimes foure, ſometimes ſix. *Euſtachius* did neuer obſerue ſo few as three, ſauing once in a Cardinall. It may be his Iawes were ſhort. And this variety *Gal.* makes mention of, although there be no ſuch variety in Apes; whence ſaith *Euſtachius* (and the obſeruation is very good) it may well be concluded, that *Galen* did vſe to cut vp not apes onely but men. Number.

The two latter grinders both in ſite and generation, are called by *Hippocrates* in his Booke *de Carnibus* σωφρονιστῆρες, *the Teeth of wiſedome*, becauſe when they growe vp a man beginneth to be wiſe: for they ariſe about the fourth Septenary, that is, at 28. yeare old, at what time men are or ſhould be temperat and moderate. In the breeding of theſe teeth there is ſometime great torment and paine, and therefore *Auicen* calleth them the teeth of Senſe. They ſpring vppe ſometime in olde age, and therefore *Ariſtotle* calleth them κραντῆρες, becauſe they perfect the age or growth: the Latins call them *Gemnuos*, to which Teeth this is peculiar, that they do not begin to breake out till all the reſt haue beene a good while perfect. Sometime alſo they onely perforate the gummes but riſe little aboue them; ſometimes they lurke al together in the iaw, and are couered with the gums; ſometime they are not created at all. The teeth of Wiſedome.

The roots of theſe Teeth are perpetually of one forme in Apes, as *Euſtachius* elegantly declareth, for in them the grinders of the vpper iaw haue three roots: of the lower iaw two, excepting ſometimes the fift; the fourth as it is the greateſt, ſo are the roots thereof greateſt. In Men their roots are not alwayes of one forme, yet moſtwhat they are many and alike: ſometime in the fift of the lower iaw, (in the ſecond alſo *Euſtachius* obſerued the ſame) which becauſe of his magnitude a man woulde thinke ſhould haue many roots, there is but one, thicke and perforated with one broad hole. Other roots of the Teeth haue an equall or vnequall ſuperficies, and within two or three holes skilfullie thrilled and diſſeuered by thin ſcales, much like a Hony-combe. In the fift grinder there are three, in moſt of the reſt two. Oftentimes the roots grow together, ſometime they are ſeparated, ſometime a man cannot perceiue ſo much as the line that parteth them. Their roots in Apes.

The Figure alſo of theſe Rootes is diuers, for ſome are round, others ſtreight and acute, others obtuſe, plaine and crooked. They differ alſo in magnitude, the roots of one tooth being thicke ſometimes, ſometimes narrow, of another ſhort, of another long, of ſome broad and thin, yet for the moſt part the roots of the vpper teeth are longer and of the lower teeth ſhorter. Their Figure.

They varry alſo in ſituation, ſome touch one another, ſome growe neare but touch not, ſome ſtraddle one from another like the feete of a ſtoole. Againe, ſome ſtande off one from another, but yet are ſo incurued that their extremtties doe touch, others running foure wayes are in their ends moſt of all diſioyned, and theſe in drawing of Teeth are ſometimes broken and put the man to cruell torment. Situation.

If there be three roots, eſpecially in the vpper iaw, one runneth inward and two outward. To conclude, commonly the two vpper grinders which are next to the *Dogteeth* are faſtned into their ſockets with two roots, the other three with three. Sometimes, the

fift hath foure which is rare. Againe, the two lower Grinders which are next to the Dog teeth haue but one roote, the three others two. Thoſe Teeth which we call *Genuini* or *Teeth of wiſedome*, haue very ſhort rootes, partly becauſe that portion of the iaw wil not admit a deepe inſertion, partly becauſe in the leuigation or chewing of meate they are not in ſo much vſe as the reſt. Wherefore the rootes of the grinding Teeth of the lower iaw are fewer and ſhorter then thoſe of the vpper, becauſe the ſubſtance of the lower iaw is harder and more ſolid, and therefore better able ſtrongly to containe the Teeth, and to beare their waight; but in the vpper iaw which is more rare and ſoft and wherein the Teeth hang, and therefore are more ſubiect to fall out with their owne weight, their rootes are longer the better to faſten them, for they needed more ties as it were to binde them and to containe them within the iaw.

Hence it is that where the rootes are ſhorter the Teeth are drawne with leſſe danger, but with more labour where they are many, eſpecially if the rootes grow vnto the ſockets.

Their perfo-rations. The rootes of all the Teeth are perforated euen into their internall cauities, yet this perforation in perfect and growne Teeth is very ſmall, and that in the ſharpe pointe or top of the roote through which a veyne, an artery and a nerue are admitted; of which Veſſels we will ſpeake in the next place but briefly, becauſe we haue touched vppon them before.

CHAP. XVI. *Of the Veſſels and Senſe of the Teeth.*

The veines. THrough the holes of the rootes of the Teeth al manner of Veſſels do run and are diuerſified in their internall cauities; veynes to bring them plentifull nouriſhment. Now it was neceſſary that the Teeth ſhould alwayes grow, becauſe in mutuall attrition they were one againſt another, & this we may certainly conclude by our owne experience. For if a tooth fal out or be drawne, that which groweth oppoſite againſt it will be longer then the reſt of the Teeth of his owne ranke, becauſe it is no more worne by the Tooth that before was oppoſite againſt it, the reſt of the Teeth by their mutuall attrition in chewing of the meat are impaired and againe ſo much increaſed.

Arteries. Arteries alſo do enter into the Teeth to preſerue and keepe their naturall heat; hence it is that in inflamations there is a beating or pulſing payne felt, ſuch as fleſhy parts feele when they are inflamed. And this *Galen* firſt of all men obſerued in the 8 chap. of his fift book *de Compoſitione medicamentorum ſecundum loca*, for he found in himſelf not only paine but a pulſing paine in his Teeth, whence he concluded that there was one paine in the Gums, another in the very ſubſtance of the Tooth. Yea without any inflamation of the Gums ſomtimes there is paine in the proper body of the Teeth, ſomtimes in the nerue.

And againe vnleſſe vnder the Tooth there were an artery, how could ſo much florid and pure bloud iſſue when the Tooth is perforated, which *Euſtachius* obſerued in a man that fell into ſuch a flux of blood that he had like to haue died vpon it.

Nerues. They haue alſo nerues ſoft and ſlender, which come from the third coniugation commonly ſo called, and runne through their rootes into their cauity, euen from their firſt conformation; where they are diſſeminated and their ſmall ſurcles are mixed with the mucous matter of the Teeth; hence it is that when that mucous matter is become bony yet it eaſily conſenteth with the nerues and the Teeth become ſenſible; whereas to other bones there are no nerues at al conuayed which may be diſperſed into their cauities. And therefore it is truely ſaide that bones want nerues although the membrane which is called *Perioſtium* haue ſenſe and nerues in it. Wherefore when this *Perioſtium* which is of exquiſite ſenſe is affected, the paine may be thought to be in the bones themſelues when it is onely in the membrane; ſo in a Cicatrice which hath no ſenſe wee imagine wee feele paine when indeed the paine is onely in the neighbour parts; and the membrane which inueſteth the Liuer being affected we thinke we feele paine in the Liuer whereas the *Parenchyma* or ſubſtance of the Liuer it ſelfe is inſenſible: vnleſſe any man will ſay that the bones haue ſenſe by the helpe of the Senſatiue ſoule by which they ſubſiſt: and yet that very obſcure, becauſe the hardneſſe of the bones doth very much reſiſt any ſuch ſenſation; and thus we may ſay that bones do differ from plants as being particles of a ſenſatiue creature.

How Teeth haue ſenſe.

Theſe nerues of the Teeth are very ſmall, yet in our Table we haue made the large imitating therein *Veſalius* and others. But by what order and manner of diſſection, we vſe to make demonſtration of the veſſels and nerues of the Teeth, ſaith *Bauhine*, wee will now relate as we learned it out of *Euſtachius*. How to demonſtrate the veſſels of the Teeth. *Euſtachius.*

Theſe veſſels are better demonſtrated in the iaw of a great creature, as for example, in an Oxe, then they are in a Man: and againe the adminiſtration is eaſier in the lower iaw then in the vpper. We take therefore the lower iaw of an Oxe and open it on the inſide, & preſently we meet a cauity full of marrow, together with the nerue inuolued in a membrane; when we haue remoued the marrow & ſlit the membrane throughout his length, then may wee perceiue the nerue made as it were of many ſtrings, betwixt which do run propagations of veines and arteries. Moreouer, if you remooue this membrane with the ſurcles of the nerues and veſſels a little vpward from the bone carefully that you break them not, you ſhall perceiue ſome fibres diſtributed from the membrane not vnlike the Lawny threds of a cob-web. In like manner in the iaw of a Ramme certaine fibres do penetrate the bony partition which is betwixt the Nerue and the Teeth, but theſe fibres are moſt conſpicuous at the roots of the grinders.

From theſe *Grinders* vnto the *Dog-teeth* and the *Shearers* there is a nerue conuayed accompanied with an arterie: the nerue is deuided into two; one part of it, through a hole in that place, breaketh vp at the lower Lip, and a branch of it runneth along vnto the *Shearers*, and affoordeth a ſmall ſurcle to euery one of them; another portion of it is ioyned with the vtter part of the rootes: the ſecond part which is alſo the ſlendereſt pearceth into the cauity of the teeth, and may euen without any greater difficulty be diſcerned euen in men.

And truely it is a ſtrange thing that the *Shearers* and *Dog-teeth* which are the leſſe and haue but one roote, haue notwithſtanding allowed them great and conſpicuous ſurcles of veſſelles attayning to their inſertion by a broade and open way; whereas the Grinders which are the greater and haue three, ſometimes foure rootes, are allowed but ſmall and capillary ſurcles made of the former, doubly, trebly and foure-fold deuided, and creeping obſcurely into their inſertion.

Againe, if a *Grinder* or a *Shearer* bee gently and by degrees drawne out of his ſocket, you ſhall finde to ariſe with it out of the cauity of the Iaw very ſmall fibres which are ioyned to the roots of the Teeth: you may alſo obſerue that the parts of the bony partition are full of a mucous ſubſtance which is not vnlike to that whereof the teeth and their huls or huskes are generated

Againe, when the Tooth is drawne, in the extremity of his roots you ſhall find a matter partly mucous partly fibrous, which carrieth a reſemblance or ſhew of a nerue, a veine and an artery.

But if you deuide the Tooth in the middeſt you ſhall finde a mucous ſubſtance wouen with veſſelles and ſome fibres: but theſe things may be better ſeen in the iaw of an Oxe or of a Ram then of a Man; and yet euen in a man diligent ſearch will find them out, though they be not ſo perſpicuous.

Wherefore who can deny but that there is a Pulſatiue or beating payne euen in the inner part of the tooth, as *Galen* and *Euſtachius* haue witneſſed, when he ſhall perceiue an arterie and a nerue attaine thereinto? For veines, why ſhould we not likewiſe beleeue that they enter into the Teeth, when wee ſee it ſprinkled with bloud in men? and in Oxen may manifeſtly perceiue the veſſell it ſelfe? for it is in the tooth as it is in that coate of the eye called *adnata*, as long as a mans Eie is well diſpoſed the veines therein are not viſible, but then onely become conſpicuous when it is inflamed.

Concerning the Senſe of the Teeth, the opinions of Anatomiſtes and Phyſitians are very diuers. Some thinke they haue no ſenſe at all, becauſe they are bones and may be filed without paine; others thinke they haue Senſe, but that of themſelues without nerues, as other bones haue: and theſe men imagine that the paine of the tooth is without it, that is, in the membrane which compaſſeth the ſocket: others thinke they liue and haue Senſe by their inbred heate. *Ariſtotle* determines that they feele cold ſooner then heate, and are more affected by it: *Galen* ſaith they are pained, they beate and receiue ſoft nerues. But the queſtion may be asked what part of the tooth hath this Senſation? *Varolius* anſwereth the body of the tooth, but on the inſide onely. Others ſay that the whole Tooth indeede hath Senſe, but the whole Tooth doeth not feele paine; it perceiueth the firſt and ſecond Of the ſenſe of the teeth Diuers opinions of Anatomiſts.

qualities

qualities, but the firſt qualities onely doe paine it, becauſe they exerciſe their power vpon the rootes of the teeth, into which certaine ſmall nerues doe penetrate. This was *Archangelus* his conceit, and *Laurentius* hath almoſt the ſame. The whole Tooth ſayeth hee doth *feele*, but more exquiſitly on the inſide more dully on the out.

Another queſtion may be asked whence comes the ſenſation that payneth them? ſome anſwere, that it is by reaſon of the nerues and of their proper ſubſtance, ſo ſaith *Actuarius*. *Falopius* thinkes the paine comes by reaſon of a thin membrane compaſsing about the inner cauity. Others aſcribe the cauſe to the nerue and the membrane ioyntly: others to the nerue which cleaueth to the neighbour partes and to the rootes of the Teeth onely. Others to the nerue that entreth the Tooth and a membrane that cleaueth to the roote thereof as it were a *Perioſtium*. Others to a nerue which penetrateth the ſubſtance.

Theſe and ſuch like are the diuers opinions of Anatomiſts concerning the ſenſe of the Teeth. *Bauhine* interpoſeth his opinion on this manner.

Bauhines reſolution. The teeth, ſaith he, do feele, and the faculty of ſenſation is communicated to their ſubſtance by the mediation of a very thinne membrane which compaſſeth the inward cauity of the Tooth lightly hanging vnto it, and alſo of a ſoft nerue which attaineth into the ſame cauity: thus the Teeth haue a proper kind of Touching which we cannot in words ſo well expreſſe as by inſtance. For vpon the eating of ſowre or ſharpe meates the Teeth are affected with a kinde of ſtupor, and then we commonly ſay our Teeth are ſet on edge, which kind of ſenſation is proper only to the Teeth and the Gums, and is nothing elſe but a Symptome of the touching faculty.

But we muſt conceiue that each part of the Tooth is not equally ſenſible, but that the inſide which is neareſt to the nerue and the membrane is of quicker apprehenſion then the outſide, for the outſide partly becauſe of the ſpiſſe and hard ſubſtance which like a ſhell couereth the inward part of the Tooth, and doth not admit the power of the nerue or the impreſsion of the animall ſpirit: partly becauſe it is continually accuſtomed to the mutations that come from the ambient ayer is not ſo ſenſible. Euen ſo we ſee that the callous skinne in the hands and feete of a labouring man is almoſt altogether without ſenſe, though the skinne it ſelfe naturally diſpoſed be very ſenſible.

Wherefore that part which is without the Gummes or the ſhell of the Tooth is not offended by hard and rough things, for though it be cutte or filed, or burnt with hot yron, yet it is not payned neyther is there any ſenſe or ſigne of ſenſe following therevppon, eſpecially the height or top of the tooth which was made ſolid to breake the meate, & therfore the cauity not attaining ſo far the nerue alſo commeth ſhort of it.

The reaſon why a part of the body of the tooth is not payned by fire or by hot iron, *Ariteus* ſayth is knowne onely to the Gods. As for vs we can ſay nothing but that it is a peculiar to the teeth that they are not equally affected eyther by all things that make alteration in them, or by thoſe things which might offend them; but are more affected by heat and cold then by any other qualities, & by cold more then by heate, yet to giue ſome ſatisfaction, we ſay that the teeth are not offended by moiſt or dry by ſoft or hard thinges becauſe their qualities are not ſo ſuddenly communicated to the membrane or to the nerue. But they are affected by hot and cold things becauſe the animall ſpirits which are contained in the ſubſtance of the tooth and diffuſed through the ſame, are thereby altered; for thoſe actiue qualities do pierce on euery ſide, affecting and changing together with their ſubſtance the animall ſpirite and by ſucceſsion alſo the membrane and the nerues.

Great ſtore of animall ſpirits in the Teeth. And truly it is very reaſonable to imagine that in the ſubſtance of the teeth there are great ſtore of animal ſpirits more thē in other bones, firſt becauſe they receiue ſoft nerues into their cauities, and againe becauſe their internal ſubſtance is ſomwhat rare, made of a mucous matter condenſated or thickneſſe.

Obſerue alſo that the paine which is felt in the ſubſtance of the tooth differeth much from that paine which is in the Gummes, eyther from their diſtemper or from any flux of humor into them, and from the payne which is felt in the nerue that runneth vnder the roote of the Tooth.

The vſe of their ſenſe. The vſe of their ſenſation is thought to be, firſt that being expoſed to outward iniuries, and hauing no *Perioſtium* to compaſſe them about; it was fitte they ſhoulde haue an ingenite principle of Senſe that they might bee able to diſcerne betwixt that which is profitable and hurtfull.

Againe,

Againe if we wil beleeue *Galen* in the ſecond Chapter of his 16. booke *de vſu partium*, as all the other parts of the mouth, ſo likewiſe the teeth doe after a ſort diſcerne of ſapors or Taſtes, and for that purpoſe they receiued ſoft nerues. For as the Skinne hath Senſe, yet through the cuticle or ſcarffe-skinne which is not ſenſible; ſo the marrow of the tooth is apprehenſiue of tactile qualities through the bony part, like as the neruous membrane which is vnder the nailes doth feele heat and cold through the nailes which haue no ſenſe at all. And ſo much ſhall haue beene ſufficient to haue ſpoken of the Senſe of the Teeth. Now wee come vnto their cauities.

CHAP. XVII. *Of the inward cauity and Membrane of the Teeth.*

WE ſaide before that the Veſſels and the Nerues did enter into the cauities of the Teeth, and therefore it would be very fitte we ſhould acquaint you what this cauity is.

All the Teeth are hollow on the inſide, [table 11. fig. 3.] but this cauity is greater or leſſer according to the magnitude or figure of the Teeth; which thing alſo *Ariſtotle* acknowledged in the 7. chapter of his 3. booke *de hiſtoria animalium*, where hee ſayeth that the teeth are bones partly concauous and partly ſolid. Notwithſtanding ſome new Anatomiſts haue been ſo impudent as to challenge to themſelues the inuention or finding out this cauity. *Galen* indeede in thoſe bookes of his which are extant, doth not write how great or what a kind of cauity this is, nor yet what is contayned therein; yet becauſe oftimes he makes mention of the *Dennes* of the Teeth, it is not likely that he was ignorant of them; for if hee had beleeued that the teeth in their firſt originall had had no cauities, it had bin an idle thing for him in vehement payne of the Teeth to commaund that their ſolid ſubſtance ſhould be perforated with a ſmall wimble or piercer, in the ninth chapter of his 5. booke *de compoſitione medicamentorum ſecundum loca*. Againe, *Hippocrates* in the 4. *Epidemion* reporteth that a Childes Teeth were eaten with a corroding vlcer, thoſe eſpecially that had cauities or were hollow, whereby *Hippocrates* doth inſinuate, firſt that the ſubſtance of the Teeth may bee corroded, and ſecondly that they haue a naturall cauity in them. The cauity of the teeth.

This cauity is in children of ſeauen yeares old and ſomewhat vpward very large, and circumſcribed with a thinne ſcale very like vnto a hony-combe. It is alſo full of a white humor, not of marrow, ſuch as we may ſee in the ſweet-tooth of a Calfe when it is broght ſodden vnto the Table, but this humour in proceſſe of time is dried, becomes harder, and for the moſt part turnes bony, and ſo the cauity is euery day diminiſhed; yet ſo that in the middeſt at the roote there remayneth alwaies a *Sinus* which ſcarcely reacheth aboue the height of the Gummes: for it was neceſſary there ſhould be an empty ſpace left, becauſe of the inſertion of the veſſels and the dilatation of the artery: yet ſome men affirme that the pulſation we feele in our teeth doth not proceede from the beating of the artery, but from a ſpirit or ayre moued, as ſometimes we finde it to be in our eares. The humour therein.

Theſe things ſayth *Euſtachius* are beſt perceiued in the *Grinding* teeth of an Oxe broken; and in a Calfe and a Lambe each *grinder* hath three cauities, one *anterior* another *poſterior* & the third in the middeſt; and the middlemoſt cauity is perforated with a crooked hole like the letter C which reacheth as farre as to the top of the Gummes: in the two other cauities there is a mucous matter contayned, which for the moſt part as the Tooth growes perfect turneth bony. Beſide, becauſe in theſe creatures we finde oftentimes two, ſometimes three, ſometimes foure grinding Teeth ioyned together, Nature to make a mutual conſent between them, hath perforated the bony partition with a tranſuerſe hole, through which a matter like a ſmall membrane paſſeth out of one cauity into another, as ſurcles of veſſels do paſſe through their perforations. 3 cauities in a calues tooth

This cauity is compaſſed with a membranous ſubſtance, which *Falopius* and *Laurentius* call a thinne membrane. *Goreus* ſaith it is a production of the *Pia mater*. *Columbus* eſteemeth it to bee made of a complication of veines, arteries and nerues, which imbibeth or ſucketh vp the matter that falleth vpon it, from whence come the greateſt and moſt intolerable paynes of the tooth-ach.

And indeed this membrane is of moſt exact Senſe, and by it the Teeth are ſo apprehenſiue of heate and cold: yea ſayeth *Bauhine* wee conſent with *Columbus* herein that the fluxe

flux of humor out of the Brain vnto this membrane is the true cauſe of the greateſt pains in the teeth which do ſo long endure as the humour is detained in the Membrane, or till the braine be purged, and ſo the cauſe of the flux be taken away.

How the teeth rottes.

By reaſon of this cauity if the teeth be perforated by an affluence of ſharpe humors, which perforation dooth reach to the cauity, then are the teeth quickly rotted euen vnto the roots, againe in this cauity, eſpecially the erotion and putrifaction of the teeth doth begin. In it groweth that dolourous rottenneſſe, and in it ſomtimes are wormes gathered which do miſerably excrutiate and puniſh the patient.

The vſe of their cauities.

The vſe of the cauity is, that by it the teeth may be better nouriſhed, and receiue the faculty of ſenſation.

CHAP. XVIII. *Of the generation and vſe of the Teeth.*

Concerning the generation of the Teeth, there are diuers opinions; ſome thinke they are generated within the Wombe, as *Columbus* and *Euſtachius*; ſome without the wombe, as *Ariſtotle*; ſome partly within and partly without, as *Hippocrates* who maketh a threefolde time of their generation, in his Booke *de Carnibus*, of a threefolde Aliment which miniſtreth matter vnto them. The firſt is from the ſuſtenance they receiue in the womb; the ſecond is after birth by the Milke which the child ſucketh; the third is after he hath caſt his teeth by the meat and drinke that he eateth whereby new teeth are engendred: for, ſaith he, whatſoeuer is glutinous in the Aliment that maketh the Teeth, but the fatty part, which heere is more plentifull then in the matter of the reſt of the bones, is exiccated by the power of the heate. So alſo, ſaith *Laurentius*, as this threefold kinde of Aliment differs in thickneſſe, ſo doth the ſolidity, hardneſſe and thickneſſe of the teeth varye, for thoſe teeth that are engendred of the Aliment which the infant vſeth in the wombe, or when hee ſuckes his mothers breſt are but ſoft and do eaſily fall away, but thoſe that are made of more ſolide meats are alſo firmer.

Diuers opinions concerning the generation of the teeth.

The truth.

The truth is that they are generated in the womb together with the reſt of the bones, with which they are not delineated but formed and abſolued by degrees: wherefore they lye for ſome time imperfect in the Iawes, neyther do they all breake their priſons at the ſame time, but ſome ſooner, ſome later, according as the neceſsity of Nature dooth require. And this is the cauſe why ſome made a double time of their generation, one in the wombe, another out of the wombe.

In the wombe after the generation of the Iawes there are twelue Teeth formed, foure of which are *Shearers*, two *dog-teeth* and ſix *Grinders*, all which do want roots and lie hid in their ſockets, on euery ſide compaſſed therwith, and the gummes whole aboue them. And this may be ſeene in the Iaw of an abortiue infant or other creature, yea if it dye preſently after the birth; for if you cut vp the Iaw you ſhall finde Teeth therein. Some haue bene borne with their Teeth out of their gummes, as of olde time *M. Curtius Dentatus*, and *Cn. Papyrius Carbo*. Of later times, the ſame is reported of *Richard* Crooke-backe the Vſurper.

The ſubſtance of the Teeth diuers.

The ſubſtance of the Teeth being yet imperfect is partly mucous and partly bony, for if you take away the huſk of the Tooth, (for there is about euery Tooth ſuch a white, mucous and ſlimy ſubſtance ſomewhat membranous wherewith the tooth is couered, which alſo is ſo much the more mucous by how much the tooth is the ſofter and the younger) perforating it in the vpper part, that the end of the Tooth may peepe out, then ſhall you perceiue that the tooth is partly bony, partly mucous; for that part which was to riſe aboue the gummes is faſhioned into a white ſcale, thin and excauated or hollowed like a Hony-combe, and ſo the vpper part of the Tooth is bony, hard and hollow.

Their hard part.

The other part which ſhould haue remained infixed in the Iaw, is ſoft, moyſt and mucous, like the ſubſtance that is in a young quill.

The ſoft part.

This ſubſtance ſeemeth to haue fibres and threds and to be couered as it were with a thin coate, for the ſuperficies thereof is like to a ſmooth tunicle faſtned and conioyned to the ſubſtaunce that it containeth: wherefore a reſemblance of the generation of the teeth wee haue ſome what expreſſely in the generation of a quill: for the part which is without the skin is horny and hard, but that which is within the wing is ſofter and moyſter, yea ſometimes like blood or congealed Phlegme. This ſoft part of the teeth as they breake the fleſh hardneth by degrees, and by degrees becommeth bony. Sometime alſo it is hollowed within and formed into roots.

The

The hull or huske of the Tooth whereof we spake euen now serueth insteade of a Ligament, for by it the tooth is fastned as with glew to the socket and to the gums.

In Infancy the Teeth be within the Gummes that they might not byte the Nurses nipple: the seauenth moneth they beginne to breake out, or later sayth *Hippocrates*, if the Infant do toothe with a Cough, and then they are troubled with Agues, Convulsions, Scowrings and such like, especially when they breede their *Dog-teeth*. *Galen* rendereth a reason, because when the Gummes are perforated by the Teeth the paine is as violent as if a goade were thrust into the flesh, but indeed the teeth are more paynfull then goades, for if a goade be once fastned it resteth, but the tooth issueth still to the extent of his augmentation.

The Teeth breake out not altogether but the vpper sooner then the lower, and the Shearers sooner then the Grinders: that they issue later in men then in bruite beastes (for the Elephant saith *Aristotle* in the 5. chap. of his 2. book *de hist. animal.* breedeth his teeth as soon as hee himselfe is borne) the reason is saith *Aristotle* because a man aboue all creatures hath lesse of that earthy excrement whereof they are ingendred. But because the first Teeth and those that follow them which are thought to bee regenerated, do lie hidden in the iaw-bone, therefore wee rather say that the cause of their late yssuing in men is to bee attributed to the good will and pleasure of him that made them, who moderateth all things according to his owne wisedome; yet when the childe comes to chewing, that he might cease to be troublesome to his mother, and not lie alwaies lugging at her brests but fall to stronger kinds of meate, therefore at length Nature put them foorth; for euery particle is then accomplished when Nature standeth in neede thereof, and this is the reason why the Teeth are not formed till after the birth. For this cause also sayeth *Aristotle* the Shearers doe yssue before the Grinders, because the meate is first shred before it bee ground. The times of dentition. The first

Dentition or the breeding of the Teeth begins about the seauenth yeare, sometimes sooner, but then saith *Hippocrates* in his booke *de carnibus*, they are ingendred of an ill humour. The first Teeth that arise are the fore-teeth; *Democritus* saith because their sharp ends make way before their due time. *Aristotle* reprehends him and giueth another reason, because that which is sharpe doth soonest grow blunt: & therefore Nature sendeth a supply of others; the broade Teeth are not blunted at all but onely leuigated by attrition, and this is *Aristotle* his conceite in the 8. chapter of his fift booke *de generatione animalium*.

When the first Teeth about the seauenth yeare are either drawne or thrust out by those that come vnder them, then doe those first Teeth appeare soft and as it were hollowed: and therefore some haue thought them onely Appendances of certaine rootes left in the iaw, of which roots, as it were of seede, a new hope or succession of teeth is broght forth. *Vesalius* therefore counsels vs to take heed that when a childes tooth is broken by accident we doe not draw the roote, for then haply the tooth will not grow againe. But Anatomy teacheth vs the contrary, that is to say, that there is no coniunction betwixt the imperfect teeth that fall at seauen yeares of age and the perfect that arise after. Nay they do not so much as touch one another, for there is a partition in the midst betwixt them before the new tooth can breake forth. And thus much of the first time of the generation of the teeth within the wombe.

The second time of their generation is without the womb, about the seuenth yeare, and these teeth are commonly thought to be Regenerated; but to say trueth and to speak properly, they are then neither generated nor regenerated. For together with the first Teeth in the beginning of generation they doe receiue with the rest a rude kinde of forme, and are made of the same matter; otherwise wee must be constrayned to confesse, (and that were very absurd) that Nerues, Vessels, Ligaments and Membranes which are spermaticall partes and doe consummate the frame of the Teeth, doe beginne their generation after the Infant is borne seuen yeares, more or lesse. It is true indeed that these latter Teeth are not sooner absolued or perfected then in the seuenth yeare or there abouts, and the proportion seemeth not to bee much amisse, for they first break out of the Gums about the seauenth month, and the second about the seauenth yeare. And this proportion *Hippocrates* in his booke *de septimestri partu* standeth much vpon, not only in the production of the Teeth, but also in other mutations in the body of man. The 2. time.

Falopius conceiueth that the latter Teeth are made of the same matter with the former

mer by the ſeminary faculty which remaineth in the iawes, and *Euſtachius* confeſſeth that if you remoue the bony partition that is betwixt the firſt and the later teeth you ſhall finde the ſeedes of the Teeth one vnder another, I meane of the Shearers and the Dog-teeth, but of the Grinders he neuer found any ſeedes, and yet he thinketh it reaſonable that they ſhould haue a rude originall in the wombe which is accompliſhed afterward at leaſure.

The number of the teeth. How they iſſue.

The teeth which about the ſeauenth yeare break out, or as ſome ſay are renewed, are in eyther iaw ten, foure Shearers, two Dog-teeth, and foure Grinders or Maxillaries that is two next vnto the Dog-teeth, and two that are called *Genuini* or *Teeth of wiſedome*. The ſhearing teeth when they breake forth do thruſt the firſt ſhearers out before them and iſſue betwixt the two firſt, the ſecond, and the Dog-tooth that is next vnto them. But if the former teeth will not fall or be not pulled out, or if the latter iſſue before the firſt fal, then the latter worke their way through new ſockets and turne in the vpper iaw outward, in the lower iaw inward, ſo that there ſeemeth to ariſe a new row of teeth, and this indeed hath deceiued many Hyſtorians and ſome Anatomiſts alſo.

The Dog-teeth alſo do fall out and the place of the ſucceeder is a little of the one ſide the roote of the former.

The reaſon why the teeth about the fourth fift ſixt or ſeauenth yeares do grow looſe, is becauſe the ſockets do continually increaſe and the teeth are but ſoft and therefore doe ſoone periſh, becauſe the harder Aliment which from thenceforth accreweth vnto them is nothing conuenable to their ſubſtance and then they putrifie and fall away: but thoſe teeth that breake out at the ſeauenth yeare receiue nouriſhment agreeable to their ſubſtance, and therefore do continue as long as their nouriſhment is ſupplyed. Among the grinders the two firſt do ſomtimes thruſt out their predeceſſors, but for the moſt part they ariſe at their ſides and increaſe the number; thoſe two that are called *Genuini* doe neuer thruſt out them that were before them, but yſſue ſomtimes in extreame old age, in the very ends of the iawes; yea *Ariſtotle* reporteth that theſe teeth haue ariſen not without great paine after foureſcore yeares. Notwithſtanding this is more rare in men then in women. *Hippocrates* in his booke *de Carnibus* witneſſeth that theſe teeth which grow vp ſo late doe wax old together vnleſſe by miſchance they fall out or periſh.

The manner of their generation.

The manner of the generation of the teeth *Fallopius* thus expreſſeth. The quickening faculty by an actiue ſpirit makes the bone hollowe; at the ſame time is ingendered a membranous huske which hath two ends, one poſterior whereat a ſmall nerue, a veyne & an artery do meete. The other anterior whereat hangeth a neruous tayle like growne Malt: and this taile creepeth through a narrow perforation of the bone to the ſide of that tooth which hath a ſucceſſor and ſo paſſeth vnto the Gums.

In the foreſaide huske there gathereth together a white and ſlimy matter, and the firſt part of the tooth becomes bony when as yet the latter part is ſoft, euen ſo as we ſaide it was in the teeth formed in the mothers wombe.

Euery tooth yſſueth through that hole dilated, through which the tayle or beard of the huske was tranſmitted. Inſtantly the huske is broken and becommeth as we ſaid before a ligament to the tooth, and the tooth it ſelfe iſſueth naked and hard, notwithſtanding the hardeſt part of it receiues a further perfection by induration of his matter without the Gums.

Their vſes.

The primary and firſt vſe of the teeth was to diuide, to breake, to chew or mitigate the meate and ſo to prepare it for the ſtomacke. Againe, another vſe of the teeth is for the forming of the voyce, for Shearing teeth are of great conſequence to true pronunciation of letters or words; and hence it is that thoſe that want their teeth cannot ſo well pronounce R, S, X, Z, yea it is thought that the ſhearing teeth in men haue no other vſe but only for elocution although the Infant doth not lightly ſpeake before he haue all his teeth, or at leaſt ſome of all kindes. VVhen he hath a few teeth he will mumble and as it were record, but cannot articulate plainely till he haue all, yet theſe ſhearers do not equally aſsiſt vs in the pronunciation of all words, only they make the prolation of ſome more cleare and facile. Thoſe words that are formed of T and R cannot bee pronounced without the ſhearing Teeth articulatly, for they require that the Tongue ſhould reſt vpon the fore Teeth. *Laurentius* ſaith the Teeth were made for ornament, but *Homer* more wiſely, that they were giuen to men to keepe their Tongues within compaſſe. *Bauhine* thinkes that the Teeth of themſelues are not onely no ornament but a fearefull ſight, and therefore Nature compaſſed and diſtinguiſhed them with Gums, couered them with

the

the lip as it were with a buckler the better to break & change the ingresse of the outward aer. Those creatures who are able eyther with their hornes to defend themselues as a Bull and Cow, or with their hooses to offend their aduersaries, those creatures I say haue teeth onely to eate withall. They that haue saw-teeth do both mitigate their meat by them and stand vpon their guard with them, for they are giuen to such creatures both to offend and to defend, whereas a man hath his hands to defend himselfe.

And thus much shall be sufficient to haue saide of the Teeth; their Sockets; their Nature, Figure, Magnitude, Number, Site, Articulation, Kindes, Vessels, Sense, Cauitie; and finally of their Generation and Vse.

And thus we haue brought to an end the history of the bones of the Scull and of the Face. Another bone there is which belongeth not indeed to the head, but much lesse vnto the Trunk or the ioynts, whose history we will therefore insert in this place because it is neare vnto the Head though it be not of it, and that is the bone *Hyois*.

CHAP. XIX. *Of the bone Hyois, called Os gutturis.*

THAT bone which from the similitude it hath with the letter υ is called *Hypsiloides*, or shorter *Hyoides*, [Tab. 11, fig. 4, and 5,] is seated in the chops before the top of the Larinx, and therefore is also called by *Galen Os gutturis*. It lyeth like a foundation vnder the basis of the tongue; and is extended directly along the necke, and the figure of it is farre other in men then it is in brute beasts. It representeth the letter υ, for the termination thereof is not in an acute angle but in a bow or bent, and therefore is not much vnlike the lower iawe, for it is not onely curued like a bow as that is, but also determineth into two processes. The figure of it was thus made that the way might be left open for the meate to passe into the stomacke and for the breath to passe and repasse to and from the Lungs; for as wee sayde euen now, it is placed iust before the chops and the Larinx.

The bone *Hyois*. His situation. Figure.

Although this bone be expressed by one single name yet is it not one bone but compounded of many, at least of three, at most of thirteene, but for the most part in antient men it consisteth of eleuen bones which are ioyned together by a laxe or dissolute composition with a gristle betweene them that they might better yeeld and giue place when they are mooued. The parts.

The ends of this bone do not touch the ends of any other, and therefore it is fastened to the neighbour parts, otherwise the tongue could not haue rested vppon it as vpon her basis. The continuity therefore that the bone *Hyois* hath, is by the mediation of muscles and ligaments, for it is continued to the lower iaw about the Chin, to the brest-bone, to the shoulder-blades, to the Appendix of the Nowle called the Bodkin; to all these I say, by that kind of Coalition which we called *Synsarcosis*, for it is bound by flesh or *Flesh bounde*. Of all the bones, that is the first which is in the middest, greater and broader then the rest, and as it were their basis. [Ta. 11, fig. 4, ABCD] On the anterior and exterior part that regardeth the mouth, it is connex and determineth into an obtuse or dul angle, which we may feele in our selues aboue the Throttle although the processes do lye very deepe. This angle was made partly to secure it from outward iniuries, partly to affoord an implantation to some muscles. On the inner or posterior side which reguardeth the chops it is hollowe, [Ta. 11, fig. 4, D. fig. *.] from which hollownes two muscles of the Tongue do arise, and beside the cauity giues way to the Epiglottis to open and lift it selfe vp.

It hath three bosomes; aboue, a transuerse depressed bosome [c] to admit the second paire of muscles which are proper vnto it, in the midst it buncheth out. [*] In the sides of this *Sinus* there are two other cauities, one on the right hand another on the left, which giue way vnto the first paire of muscles that are implanted into the sides of this bone. Cauities.

It hath also two processes on either hand arising out of the basis, [EFIK] which some cal *Hornes* or *Ribs*, by which it is ioyned to the two lower neighbour bones. Processes.

The two lower which make the second and third bone [EF] do consist on either hand of one bone; they are shorter and broader then the vpper, and are fastened to the bottome of the sides of the first or middle bone [Tab. 11, fig. 4, C] by the interposition of a gristle & a good broade gristly ligament. At their extremities [HK] because they are not ioyned with any other bone, they couple themselues with the processes of the shield-gristle of the throttle, & these processes together with the middle bone make the shape of the letter υ. The 2 lower.

But because this bone hangs like a meteor, it would not haue had sufficient strength if it had bin only ioynd with the gristle of the *Larinx*; Nature therfore aded 2 other processes to bind it The 2 vpper.

it and firme it to the Appendix called *Styloides*, which is faſtened to the Temple-bone, and by this meanes being ſo on each ſide bound, the bone *Hyois* ſtandeth ſtedfaſt in the middeſt. Wherefore the two vpper proceſſes which make the fourth and the fift bones [I K] and are ſlender, round and long, are faſtned to the vpper part of the ſide of the firſt or middle bone. To theſe proceſſes are oftentimes added on either ſide 3 ſmall Bones, which make the ſixt, ſeauenth, eighth, ninth, tenth and eleuenth bones. They are faſtened with round and ſlender Ligaments to the extremities of the appendix *Styloeides*; ſo that as the two lower proceſſes or the ſecond & third bones together with the firſt make a reſemblance of the letter *v*, ſo alſo the two vpper proceſſes or the fourth and the fifte bones, and thoſe that are aſsiſtant vnto them together with the firſt bone, do again make another *v*, ſo that this bone may well be called *Hypſiloeides*, becauſe there reſulteth a double *vpſelon* out of his figure.

Sometime the vpper proceſſe on either ſide conſiſteth of one ſhort and ſlender bone, and is faſtned to the Appendix *Styloeides* by a neruous Ligament. Sometime it hath only the inferior proceſſes and the vpper bones as the fourth and the fift, and all the reſt to the eleuenth eſpecially in women are wanting, as we haue expreſſed it in the fift figure of the eleuenth Table, and then their place is ſupplyed by long, round, ſtrong and neruous Ligaments, which yſſuing from the firſt or middle bone do paſſe vnto the proceſſes *Styloeides* on either ſide, and then there are onely three bones. Afterward as a man growes in yeares, thoſe which were at firſt but additaments do grow dry and harde, and ſo the Number of the bones is increaſed, till they come to ſeuen, then to nine, after to eleauen, and ſometime though rarely to thirteene.

Sometimes wanting.

How it is eſtabliſhed

Finally, leaſt the bone *Hyois*, ſaith *Galen* in the eleuenth chap. of his 7 book *de vſu par.* ſhould be diſplaced from the middle Region of the Larynx, and leane too much to one

ſide,

ſide, Nature hath prouided muſcles which ballance it and keepe it equall, and not only ſo, but alſo certaine ſtrong Ligaments in the two ſides of the bone *Hyois*, yea and others that are griſtly and round which ſhe hath inſerted on each ſide; and as if all this were not ſufficient, it is faſtned by certaine membranes not onely to the *Larynx* and *Epiglottis*, but to make it more ſtable, to the Gullet alſo.

The vſes of the bone *Hyois* are very great though it be but a little bone, and very many. It was framed therefore for the tongue and the *Larynx*: firſt to bee a *Baſis* for the tongue aboue which it might be moued diuerſly and ſuddenly, like an Eele ſayth *Laurentius*. The ſecond vſe of it is to lift vp the *Larynx*. A third, that from it many muſcles might take their originall, that is to ſay, ſome of the tongue or the fourth payre. The fourth payre from the firſt of the middle bone, the fift payre from the fourth and fift bone when they are there, when the fourth and fift are wanting then it ariſeth from the ſecond and third bones. The vſes of the bone *hyois*

The muſcles alſo of the *Larynx* take their originall from hence: the *anterior*, that is to ſay, the beginning of the firſt and fourth payres of the foure common muſcles from the lower part of the firſt bone: and thus wee ſee howe the bone *Hyois* was ordayned to eſtabliſh the muſcles of the tongue and the throttle. And ſo much of the bone *Hyois*, now we proceed.

CHAP. XX. *Of the Spine in generall.*

WEe deuided the *Sceleton* before into three partes, the Scull, the Trunke and the Ioynts. The Scull we haue proſecuted as narrowly as we could; the Trunk we alſo deuided into the Spine, the Cheſt, and the Bone without a name. Vnder the name of the Spine we comprehend all that which is extended from the firſt Racke-bone of the Necke vnto the *Coccyx* or Rumpe: and this the Grecians call ῥάχις, becauſe the backepart of it is ſharpe and ſpinie. It is called alſo *dorſum* or the Backe, becauſe the Backe is the greateſt part thereof.

This Spine is the habitation or ſeat and defence of the Marrow as the Scull is of the Braine. For becauſe the dignity or woorth of the Marrow of the Spine is equall to the worth of the braine (for it is the originall of all the ſinnewes excepting ſeauen coniugations, and therefore is called the Braines Vicar or Subſtitute) Nature was no leſſe carefull of the preſeruation thereof then ſhe was of the Braine it ſelfe. As therefore the Brayne was compaſſed with the bones of the Scull as with a Helmet, ſo the Spinall Marrow is walled in on euery ſide by the Racke-bones of the Chine. What the ſpine is. The dignity thereof.

This that Nature might the better accompliſh, firſt ſhe hollowed the Spine throughout, then ſhe exaſperated it with many proceſſes both acute and tranſuerſe, thereby as it were flanking the bulwarke againſt all annoyance. The cauity is large, the better to containe the Marrow, in which reſpect the whole Spine is called σύριγξ ἱερὰ the *Sacred Pipe*, by *Herophilus* the Canale. The Spine therefore is bony, not made of one but of many compacted together, as well to helpe the variety of motions becauſe it was fitte the creature ſhould moue forward and backward, as alſo to preuent danger; for the luxation ſaith *Hippocrates*, of one Rack-bone is more dangerous then of many, becauſe it conſtrayneth the Marrow into an acute angle, and ſo doth neceſſarily either breake it or compreſſe it very ſore. Why the ſpine is hollow.

Theſe Bones that make the Spine are called σπόνδυλοι from the ſimilitude the haue with the whirle of a wheele. They are alſo called *vertebra*, becauſe by them the body is *turned* into diuers parts. *Pliny* calles them *oſſa orbiculata* round or *Nut-bones*. This Spine is the *Baſis* and foundation of the whole building, and therefore the auncients compared it to the carkaſſe of a Ship, for as the crooked ribbes and elbowes of a Shippe are faſtned to the bulke, and afterward the prow and the ſterne or caſtle are annexed, right ſo the ribbes the Armes and the Legs are faſtned to the Spine. Why made of manie bones.

The figure of the Spine *Hippocrates* firſt elegantly expreſſed in the third Section of his Booke *de articulis*, and in his Booke *de natura oſſium*, where he ſayth it is ἰθυκύλιος, that is, *after a manner direct or ſtraight*: yet ſo that it inclineth ſometime backeward ſometime inward. From the firſt Rackbone of the Necke vnto the ſeuenth it inclineth inward that it might ſupport the Gullet and the rough artery. From the firſt Racke of the Backe vnto the twelfth it beareth outward, to leaue more ſpace for the organs of Reſpiration, that is, for the Heart and the Lungs. The Loynes incline inward to ſupport the deſcending The figure of them

trunkes of the hollow veine and the great artery. The holy-bone protuberateth outward with a kinde of rectitude or ſtreightneſſe to make the capacity of the *Hypogaſtrium* or water-courſe better able to conteine the bladder, the right gut and the wombe.

We alſo will add, ſaith *Laurentius*, that the fore and inner part is equall that it might not offend the bowels yet ſcored throughout with tranſuerſe inſcriptions: the backeſide is vnequall for the better inſertion of muſcles, and the ſafer egreſſe of the veſſels.

4 parts of the Spine.

The Spine may be diuided into foure parts, the Necke, the Backe, the Loines, and the Holy-bone. The Rackes of the necke are ſeuen, of the backe twelue, of the Loines fiue, whoſe articulation and coalition is ſtrange and wonderfull. The articulation is double, forward and backward; the forward articulation is made by the bodies of the Spondels, and is more ſtrict and cloſe: the backward or hinder articulation is made by the oblique proceſſes and is more lax or remiſſe, partly that the creature might mooue more eaſilie forward, partly leaſt in bending backward the veſſels ſhould be diſtended, compreſſed, or broken. In a word, there are ſixe articulations of the rackbones, two by their bodyes, and foure by their oblique proceſſes aſcending and deſcending. That articulation which is made by the proceſſes belongeth to *Ginglymos*, for euery racke (excepting the firſt and the eleuenth) receiueth an vpper and is receiued by a lower, ſo that for the making of the *Ginglymos* there muſt be three rackes.

The artic tion of thn'a- Rackes.e

The *Symphyſis* or coalition of the Rack-bones is not *Griſtle bound*, although their extreamities bee lined ouer with a griſtle, but by Ligaments and thoſe very ſtrong, ariſing from the bones, from the griſtles, and from the membranes that inueſt the bones.

TABVLA XII.

See this Tables deſcription, in fol. 771.

What the Rackbones haue in common.

All the racke-bones of the Spine haue many thinges in common. Firſt euery rack hath his body ſeated on the inſide thicker and more fungous the the reſt of the bone, to which alſo Appendices do grow & griſtles. It is broade both in the vpper and in the lower baſis to make the articulation more ſecure leaſt it ſhould lux ſideward. Againe, euery racke hath a large hole wherein the narrow is contained, and this perforation is in all the rackes equall, ſaith *Laurentius*, for he neuer could obſerue it larger aboue or narrower below, although ſome haue thoght the contrary. But, ſaith *Laurentius* although the wonderfull fruitfulneſſe of the Marrow of the backe in propagating Nerues be by degrees diminiſhed, yet thoſe lower cauities are filled vp with thicker Membranes, prepared more ſtraitely to vnite the thicker Bodyes of the Spondels. Thirdly, in euery rackbone there are three kinds of proceſſes, oblique, tranſuerſe and acute. The oblique are foure, two in the vpper part and as many in the lower; the vpper aſcending, the lower deſcending, and by theſe are the Hinges of the backe hung together, for the articulation is made by *Gynglimos*.

The tranſuerſe proceſſes are two, made to ſecure their muſcles and for their originals and inſertions. The acute proceſſe is ſingle, ſeated in the backepart, and giueth the name

vnto

vnto the whole, for it is called ῥάχις or the *Spine*, and this is wanting onely in the first Racke.

Fourthly, in euery Racke-bone there are fiue Appendices, two in the body, two in the transuerse processes, and one in the Spine.

Finally, euery spondell which is articulated with another, hath a perforation which affordeth an outlet for the nerues, produced from the Marrow. Notwithstanding this perforation is not after the manner in all the Racks, for in those of the Neck the lower is deeper then the vpper: in the spondels of the Backe, the semicircle of the vpper and the lower is equall: in the *vertebræ* of the Loynes the whole cauity almost is formed by the vpper. And these things are common to all the Racke-bones. Now in their particular history wee shall see what is proper to euery one of them; but first you shall haue a Table to shew you all the Rack-bones of the Spine from the top to the bottom.

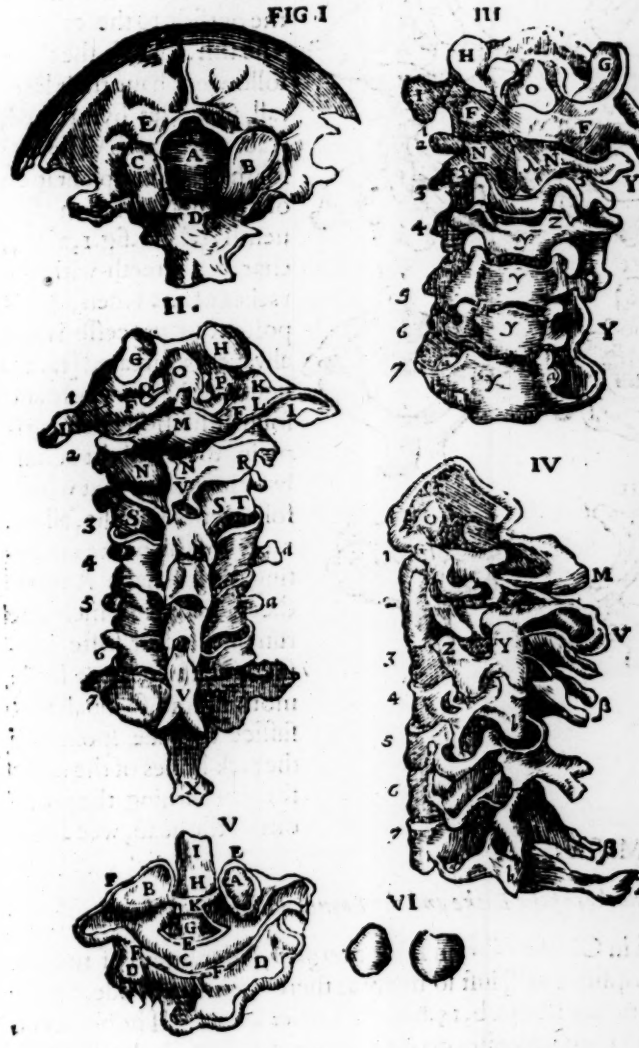
CHAP. XXI. *Of the Rack-bones of the Necke.*

THE vse of the whole Necke and his admirable structure doeth not belong to this place, and of it we haue spoken before: here wee haue to doe onely with the Bones, which are commonly seauen [table 13. fig 2.3.4.] differing both amongst themselues and from the other Racks of the Spine.

The two first are ioyned to the Nowle by Ligaments, whereby the head is strongly fastned to the necke. The first of these [ta.13.fig.2.3.4.[ff] ta.14. figu.2.3.4.] is called *Atlas*, because as he was imagined to hold Heauen vppon his shoulders, so this especially beareth vp the Head. The body of it is more slender but faster then the rest, and it wanteth his vpper processe or his Spine, least it should haue hurt twoe small muscles of the head: but ascending and descending processes it hath like the other Racke-bones, which in this are hollowed on either hand [tab. 14. fig. 2. 2.[rr]] Aboue to receiue two processes [ta.13.fig.1.[bc]] of the nowle-bone to help the motion of the head. *Galen* thought in compasse, but *Colũbus* reproueth him who sayeth that by this articulation the head is inclined and reclined, that is, moued forward and backward. Below it receiueth the processes of the second Rack-bone. [tab. 14. fig. 5. and 6.[MN]] It hath also at the sides two transuerse processes [tab. 13. fig. 2.3. I I ta. 14. fig. 3.4.[oo]] perforated [tab. 13. fig. 2.[x] tab. 14. fig: 2.[x] sheweth the hole] for the ascent of a veine and an artery into the braine.

Racks of the necke. 1 *Atlas.*

TABVLA. XIII.



See this description lib. 6. fol. 397

It hath also a *sinus* or bosome [t. 14. fig. 2, 3.[b]] crusted ouer with a gristle [fig. 3.4.[c]] the better to receiue the tooth [fig. 7 O] of the second racke,

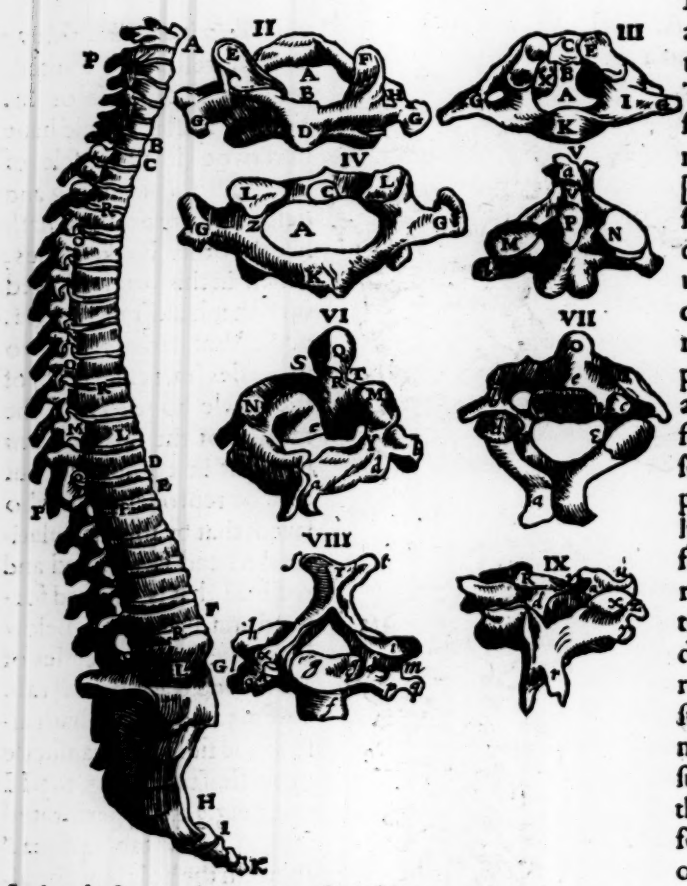
racke, and at the proceſſes where the rackes are ioyned there is a ſinus on either hand: in the firſt [fig.4 z] and the ſecond [fig.6 x] bearing the forme of a rift or cleft. In the other rackes it is orbicular, ſauing that in the Cheſt it is ſomewhat long. Through theſe ſinus are conueyed coniugations of ſinewes and branches of Veines and Arteries, miniſtering nouriſhment to the marrow and to the bones.

The ſecond Racke [Tab.13. fig.2,3,N tab.14.fig.5,6,7] beſides his bodye, his laterall proceſſes [tab.14.fig.5,6,7 b] ſhort and perforated with an oblique hole, [fig.7.c] his Poſterior proceſſe byfurcated in reſpect of the muſcles, [figu. 5,6,7 a] his aſcending proceſſes lightly bunching out, and his deſcending [tab.13.fig.2 R. tab.14,fig.6,7,d] lightly ſinuated; beſide all theſe, I ſay, there yſſueth out of the middle of his body an appendixe (commonly called a proceſſe) round and long, [tab.13,fig.2,3,4 O. tab.14. fig.6, e. fig. 7,O] which becauſe it is like the Dog-tooth of a man, is called the Tooth. *Hippocrates* calleth the whole Racke the tooth, and in the luxation therof, ſaith he, happeneth the moſt incureable Squinſey. This Appendix is ſomewhat rough in the ſurface, that from thence a Ligament might yſſue [tab.13.fig.5 t] by which it is faſtned to the Nowle; about it alſo is caſt a ſolid and round [tab.13.fig.5 u] ligament to keepe the marrow from compreſſion. Moreouer this ſecond racke is ioyned to the firſt by a broad Ligament [tab.14. f. 5 r] which is orbicularly caſt round about it.

TABVLA XIIII.

See this Tables deſcription, in lib.6. Fol.398.

FIG. I



3 and the reſt

The third Racke-bone, [Tab.13.fig.2,3 SS. tab.14 fig.8 and 9] is called ἄξων. It is ioyned moſt ſtrictly and exceeding firmelie on the outſide to the other 4. The third, as alſo the three following, haue their laterall proceſſes byfurcated, [tab.13,fig.2 V,V. fig.4 g] for the better implantation of the Muſcles; but the ſeauenth [tab.13.fig.1,2,3,4. char.7] agreeth with the rackes of the Cheſt, & his poſteriour proceſſe is not alwayes byfurcated [ta. 13. figure 24 X] but whole and ſound: his body belowe is plain, that it might equally be ioyned to that which followeth. Finallie, all the rackes of the necke excepting the firſt haue Appendices, betwixt which doe run thicke and ſofte Griſtles for their more facile motion. And ſo much ſhal ſuffice to haue ſpoken of the rack-bones of the neck; for concerning the motions of the head, wee haue ſpoken before in the Booke of Muſcles.

CHAP. XXII. *Of the Rackes of the Backe and the Loynes and the Holy-bone.*

How the rackes of the necke and the backe differ.

THe backe is called in Greeke νῶτος, in Latine *tergum*, it conſiſteth of twelue rack-bones, [tab.14.fig. 1 at n] iuſt ſo many as there are ribs on a ſide, for to euery rack-bone are two ribs [tab,15.fig. 5 n r] articulated. The bodies of theſe Rackes as alſo their proceſſes do differ ſomewhat from the bodies and proceſſes of the rackes of the Neck. The bodies of the necke are long, broad and

and equall, that vpon them the Gullet and the Rough Artery might leane more ſecurely.

The bodies of the backe are round, conuex or embowed, thicker alſo and not ſo ſolid. The ſpinall proceſſes of the necke are byfurcated, thoſe of the backe are long, ſimple and do bend downward. The tranſuerſe proceſſes of the necke are broad and perforated. Of the backe, thick, ſolid and round, to make the articulation of the ribs more firme, excepting the eleuenth and the twelfth, to which the laſt and the ſhorteſt ribs are faſtned, that there might bee more ſpace left for the Liuer, the Spleene, and the parts thereunder.

Of the twelue Rackbones of the back, ſometimes but rarely there is one wanting, more rarely is there one too many, yet for the moſt part dogs haue one more then men. They were made many for the better flexion of the ſpine, and are faſtned together with ſtrong Ligaments, [tab.14.fig.1 RR. ta,15.fig.6 ch.5] yet there is a good quantity of griſtle betwixt each of them. [Tab.15,fig.6. char.1,2]

The firſt racke of the backe is called by the Ancients λορίκα becauſe it ſtandeth out beyond the reſt; the ſecond is called μεσοχαλίνιος, that is, the Axillary ſpondell: the eight following πλευρίται, that is, *Coſtales* belonging to the ribs. The eleuenth [ta.15.fig.5] called ἀβέρτιος, becauſe his ſpine is right, and this like a naile faſteneth the other rackes. *Laurentius* addeth, that it is quite contrary to the firſt, for the firſt receiueth and is not receiued, this eleuenth is receiued but doth not receiue. The twelfth is called [t.15.fig.4] διαζώνιος, the compaſsing ſpondell. The firſt.

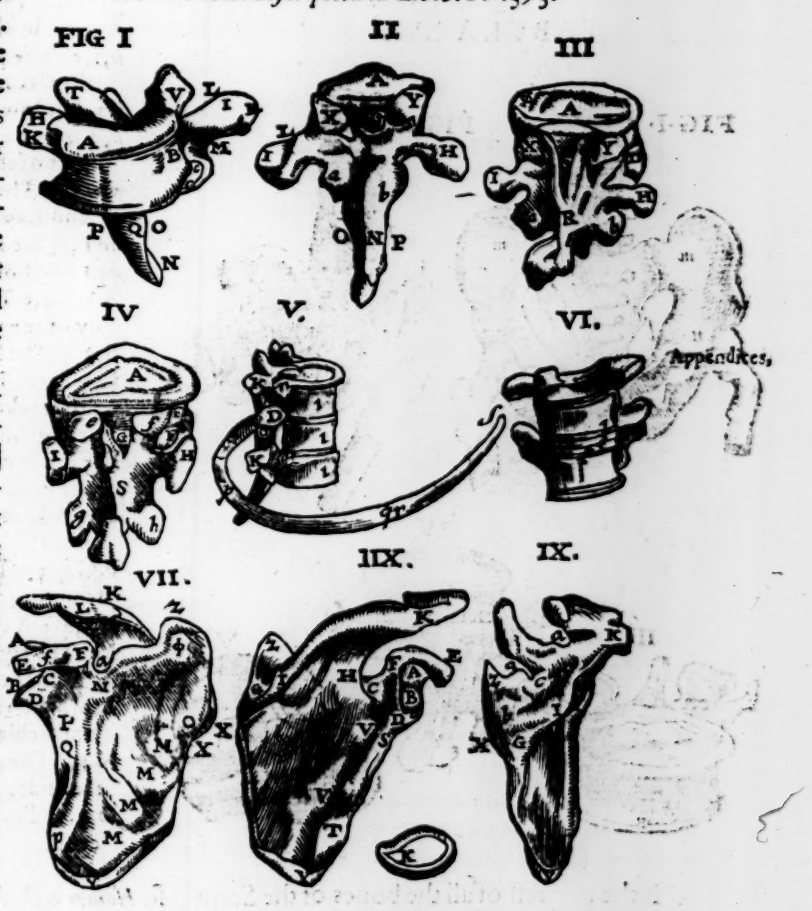
Theſe Rack-bones haue in the middle protuberating, round and embowed bodies, [tab.15.fig.1] aboue and below [tab.15.fig.1,2,3,4 A] plaine, thicker then the Rackes of the necke and leſſe ſolid; full alſo of ſmall perforations for the tranſportation of the veſſels that carry the nouriſhment. Their ſpinall proceſſes [ta.15.fig.1 and 2 N O P] are long, ſimple and accute looking downward: the tranſuerſe alſo [tab.15.fig.1,2,3,4, H I] for the firmer articulation of the Ribs are craſſe, ſolid and long, determining into a round head. Their Figures

They haue alſo aſcending proceſſes two [tab.15,fig.1 T V] & as many deſcending. [tab.15,figure.2,3 a b] The tranſuerſe proceſſes of the eleuenth and twelfth racks [tab.15.fig.4 e f g h] do differ from the proceſſes of the other ſpondels, which variety *Galen* attributed to the tenth racke, for in a Dog or an Ape the tenth is the middlemoſt, but in a Man the twelfth.

They haue alſo fiue Appendices, two at their bodies aboue [tab.15.fig.3,4] & below; two at the tranſuerſe proceſſes, and one at the extremity of each ſpine. They haue alſo two ſinus or boſomes; [tab.15.figu.1 from C to D] one at the ſides, another in the Tranſuerſe proceſſes, both ſmall & anſwerable to the heads of the ribbes, for into them the ribs are articulated. The holes of theſe Racke-bones [Table.15.figu.2,3,4 c] are proportionable to the marrow which they containe, and though *Laurentius* will not agree therto yet *Bauhine* conceyueth that the marrow is attenuated in the deſcent, and ſo the holes of the lower rack-

TABVLA. XV.

See this Tables deſcription in Lib.6. Fo'.393.



bones

bones become ſtraiter. And ſo much of the backe.

The Loines make the third part of the ſpine, and do conſiſt of fiue Spondels [ta.16.fig. 12 from [b] to [c]] the greateſt and thickeſt of all the reſt which are faſtened by Griſtles and thicke Ligaments; aboue, with the rackes of the Cheſt or the backe, [tab.16.fig.2 *a* ſheweth the laſt racke of the backe] below, with the Holy-bone, [tab.16.fig: 1 & 2 [c]] for they lye vpon them, and are articulated by the interpoſition of a Ligamentall griſtle; yet ſo, that the motion of the Loines is more lax and diſſolute then that of the backe: the Reaſon was, becauſe we might better incline our ſelues vnto the earth.

The firſt Rack of the Loynes is called νεφρίτης from the Kidny which reſteth it ſelfe vpon it. The laſt is called by ſome ἀσφαλίτης, that is, the ſupporter or the ſtrengthner.

The Rackes of the Loynes, beſide their lateral perforations made for the tranſmiſſion of the Nerues, are alſo thrilled through with ſmall holes.

Their proceſſes are Aſcending. [Tab.16.fig.4 & 5] Deſcending [fig.4 [ee]] & tranſuerſe, [fig.2 [cc] fig.3,4,5 [ee]] longer and ſlenderer then in the reſt: but their acute proceſſes which they call the *Spine* [tab.16.fig: 3,4,5 C D] are thicker then in the reſt and broader, that to them the Ligaments and muſcles of the backe might be faſtened. The Spondels alſo of the Loines (ſaith *Laurentius*) haue proceſſes like a Medlar ſtone, which is found ſometime in them all, ſometimes onely in the vppermoſt. And ſo much of the Loines.

The Holy-bone, called *Os ſacrum* and ἱερὸν, not becauſe it containeth in it any ſacred and hidden myſtery, as ſome haue fondly imagined, but becauſe of his greatneſſe, for it

E 5, A ſinus or cauity at the ſide of the line D.
F, G, 4,5. The appendixe of the ſpine reſembling a triangle.
H 3,4,5 A tranſuerſe proces on either ſide
I, 4. The right aſcending proceſſe.
K, A ſinus of the left aſcending proceſſe.
L, M, 4,5, the browes of this ſinus before and behinde.
N 4, The deſcending proceſſe of the other ſide.
O, 4,5. The head of that deſcending proceſſe.

is the greateſt of all the bones of the Spine, ſo *Homer* calleth great Fiſhes *Piſces ſacros*; and *Hippocrates* for the ſame reaſon calleth this Holy-bone *vertebram magnam* the *Great rack-bone*. It is alſo called πλατύ the broad bone. The figure of it is almoſt triangular, hauing

ning a broade beginning, and ending by degrees into a narrowneſſe. Immoueable it is and maketh the *Baſis* of the backe. *Galen* ſayth it conſiſteth of three bones, by which hee vnderſtandeth the three firſt, but the trueth is, that it is made of fiue bones [tab. 10. fig. 1. & 2. from c to d ta. 17. fig. 6. from A to F] as it were of proper racks knitte and faſtned together by griſtles, which in growne bodies are ſo faſt glewed that it ſeemeth to be but one bone, whereas in children the griſtles betwixt the bones are very euident.

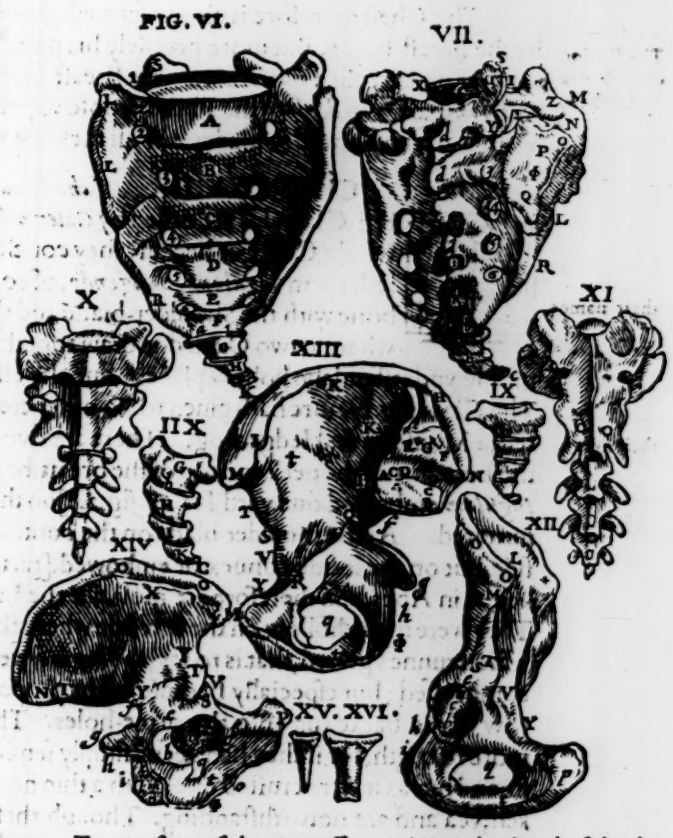
This Holy-bone on the foreſide is hollow, ſmooth and equall; behind it is incurued or gibbous, rough alſo becauſe of the Ligaments and the muſcles of the backe. His acute proceſſes are very ſmall, the tranſuerſe [ta. 17. fig 6. and 7.x] but obſcure, and determining into a cauity ſhallow, vnequall and rough, which receiue the hanch-bones: aſcending proceſſes onely the firſt racke of the Holy bone is allowed [tab. 17. fig. 6. 7.y] by which it is articulated with the deſcending proceſſes of the laſt ſpondels of the Loynes. In the ſides of the three vpper bones there are certaine *Sinus* or boſomes inſculped, to which the hanch-bones doe ſo cleaue and are articulated [table 17. figu. 7.M] that they ſeeme to grow together.

It hath alſo Spines [table. 17. fig. 7.dddd] looking downeward, which in the fift and ſixt bones are deuided into two parts. The perforations of this Holy bone [ta. 17. fig. 6. and 7. char. 1. 2. 3. 4. 5. 6 ſhew the holes of the nerues; fig. 7.efghik ſhew the holes for the marrow] are before and behind, not on the ſides as in the other Rack-bones, becauſe the haunches do occupy them, and the *anterior* are greater then the *poſterior*, becauſe greater nerues are diſtributed into the fore parts and into the hind parts.

At the end of the Holy-bone appeareth the Rumpe-bone called *Os Coccygis*, [tab. 16.

TABVLA XVII.

Table 17. Fig. 6. ſheweth the fore ſide of the Holy-bone & the Rump. Fi. 7. the backeſide. Fig. 8. the Rumpe-bone of a man curued forward. Fig. 9. the Rump bone of a woman curued backeward. Fig. 10. ſheweth the foreſide of the Holy and Rump-bones of an Ape. Fig. 11. their backeſide.



From A to F 6. The ſixe parts of the Holy bone placed vnder the fift racke of the Loynes.

From G to K 6,8, foure bones of the *Coccyx* or rumpe which cleaue to the Holy bone.

L L 6,7, The large tranſuerſe proceſſe of the ſecond Holy-bone, for the reſt as farre as R are by degrees anguſtated or ſtraytned.

M 7, an vnequal boſom of the Holy bone to which the right hanch bone is ioyned.

N 7, the *exterior* part of this *ſinus* which is the plainer.

O 7, a long protuberation diſtinguiſhing this *exterior ſinus* from the *interior*, noted with Φ.

Φ 7 the *interior ſinus* vnequall.

P Q 7, the vpper and lower part of this *ſinus*.

R 6,7, a ſwelling of the tranſuerſe proces whereto a ligament is ioyned.

S 6,7, The aſcending proceſſe of the firſt bone. T 7, a *ſinus* of the proceſſe receiuing the head of the deſcending proceſſe of the fift racke of the Loynes. V X 7, the browes of this *ſinus* on either hand. Y 7, The connexion of the deſcending proceſſes of the firſt bone, with the aſcending proceſſes of the ſecond bone. Z 6,7, the coniunction of the tranſuerſe proceſſes of the firſt and ſecond bones. *a b* 7, the connexion of the Holy-bone with the Rumpe. *b b* 6,7,8, a griſtly ligament comming betweene the looſe connexion of the Rumpe bones. *c* 7,8, a griſtle growing to the end of the Rumpe bone. *d d d d* 7, the ſpines of the Holy-bone. *e f g h i k* 7 Holes betwixt the diſtances of the ſpines made for the tranſmiſſion of the ſpinall marrow. 1,2,3,4,5,6, in fig. 6, & 7, holes through which the Nerues of the Holy-bone doe paſſe.

fig.

fig.1.and 2.[d] tab.17.fig.8.and 9.]becauſe it is like a Cuckoos beake. *Galen* calleth it an *Appendix*, and vnder that name vnderſtoode the three lower bones that belong to the Holy-bone.

This Rumpe conſiſteth of three or foure bones[ta.17.fig.6.and 8.from [o] to [x]]and two griſtles. One where it is faſtned but looſely to the Holy-bone[tab.17.figu.6.and 7.[a]]that it might yeeld backeward when the thicker excrements are auoyded, and when wee ſitte downe returne forward into his place. In men it is curued or bent more inward to ſuſtaine the right gut, but in woemen outward, becauſe of the necke of the wombe. The ſecond griſtle is at the very extremity or end of it,[tab.17.fig.3.and 7.[c]] ſometimes alſo it is placed betwixt his firſt and ſecond bones.

That this Rumpe-bone in the time of the birth is retracted or drawne backward, we doe no more doubt ſayeth *Laurentius* then wee thinke it impoſſible that at that time the ſharebones ſhould be diſioyned. And thus haue we brought to an end the Hiſtory of the Spine which we made the firſt part of the Trunke. Now we proceed vnto the Cheſt.

CHAP. XXIII. *Of the bones of the Cheſt in generall.*

THE ſecond part of the Trunke is called *Thorax*, a word which ſignifieth to leape, for the heart therein contayned is moued with perpetuall ſubſultation. Wherefore becauſe it contayneth ſo noble a bowell, ſo neceſſary for the maintenance of life, therefore Nature hath defended it with bones. But againe becauſe in Reſpiration it muſt continually bee diſtended and contracted, therefore it was made alſo partly fleſhy. The fleſhy part wee haue deſcribed in his proper places, that is to ſay, in the ſixt and tenth bookes. The bony part though we haue touched before in the ſixt booke, yet becauſe it pertained properly to this place, we will attend it here more diſtrictly.

The diuiſion of the bones of the cheſt.

The Cheſt therefore is circumſcribed or bounded out aboue by the clauicle, below by the Breaſt blade. But more preciſely his parts are *anterior* or *poſterior* or *laterall*. The *anterior* part is called στῆθος *Sternum* the Breaſt-bone: the ſides πλευραὶ *coſtæ* the Ribs: the *poſterior* part νῶτον *dorſum* the Backe, whoſe vpper ſides are called ὠμοπλάται & πτερύγια the Wings or the Shoulder-blades, and all theſe we will deſcribe in their order.

CHAP. XXIIII. *Of the Clauicles or Coller Bones.*

their names.

THE Clauicles are called by *Galen* κλεῖδες becauſe they cloſe or ſhutte vp the whole Cheſt, or becauſe they conclude the Arme and the Necke. *Celſus* calleth them *Iugulum a iungendo*, of coupling, becauſe they couple the Breaſt-bone with the Shoulder-blade and the Arme, for they are very like the yoke wherein two Oxen doe draw together, but by the name *Iugulum* wee commonly vnderſtand the hollow place aboue the clauicles where they vſe to ſticke a Swine.

their figure.

The Clauicles Nature hath giuen to no other creature ſauing to a Man, an Ape, a Squirrell, a Mouſe and a Hedge-hog. There are two, one on each ſide, ſeated ouerthwart in the bottome of the neck and top of the breaſt-bone. Their figure is not ſtreight, but at the *Iugulum* embowed outward,[ta.18.fig.2.[n]]on the inſide they are concauous or as it were guttered. At the ſhoulder-blade on the contrary they are lightly hollowed on the outſide, but on the inſide conuex or embowed.[ta.18.fig.1.2.3]. In men they are not ſo crooked as in Apes, and therefore are moſt like the Latin letter *ſ*, but in Apes more like the S. They were made hollow on the foreſide where they regard the *Iugulum*, that the veſſelles which runne vpward, that is to ſay, the *Iugular* veines and the ſleepy arteries might not be compreſſed; but eſpecially becauſe of the propagations of ſinewes, which from the marrow of the backe run vnto the arme-holes. They haue in them a double ſemicircle for more ſtrength, for if they had beene ſimply ſemicircular being fiſtulated and ſpongy within, and but as it were cruſted ouer with a thin bony ſcale, they might eaſily haue been broken, yea and are notwithſtanding. Though theſe bones are long, craſſe and crooked, yet they are more crooked in men then in women, that the motion of a mans arme might be at better commaund; but in women [ta.18.fig.4.[x]] they are leſſe curued and ariſe higher;

How they differ in men and women.

hence it is that women are ſo auckward when they throw a ſtone or ſtrike a ball, but Nature made recompence, for her necke is ſo much the more beautifull and ſtately built, becauſe there is no ſuch hollownes in it as is in a mans.

Their protuberations.

They bunch ſomething forward, and haue two riſing lines in them [ta.18.fig.1,3.[r] fig. 2.[r o]] from which the *Subclauian* muſcle and a part of the pectorall muſcle do ariſe. They

haue

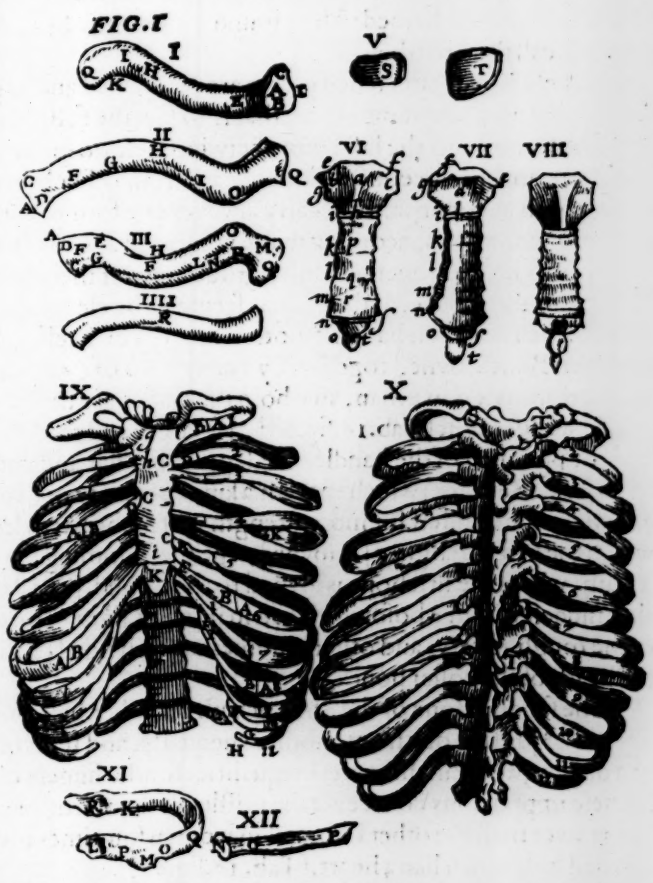
haue alſo a knub or protuberation from whence ariſeth a Ligament which goeth to the inner proceſſe of the ſhoulder-blade. [tab. 18.fig.3. It ariſeth about ^N] Neere their endes they are alſo on both ſides exaſperated, and from that roughneſſe proceede Ligaments, and the muſcle called *Maſtoides* or the ſeuenth of the heade. But where the Clauicle is broad, there it affoordeth an originall to the muſcle *Deltois*, and inſertion to the ſecond muſcle of the blade.

Theſe Coller-bones faſten on both hands the ſhoulder-blades with the breaſt-bone by *dearticulation*, yet there commeth betwixt them a large griſtle [tab. 18.fig. 5 ^T] which is moiſtened with an Oyly humor. And this griſtle is called *κατακλεῖς clauſura*, becauſe it cloſeth them together, yet doth it not grow vnder them, but is onely held downe by the Ligaments that compaſſe the ioynt, that in the motions of the arme and the ſhoulder it might giue a little way.

It hath two heades, one ſmaller, cruſted ouer with a griſtle [tab. 18. fig. 1, 2, 3, ^A] whereby it is ioyned to the breſt-bone as we ſayd: the other is broade and ſomewhat long [ta. 18. fig. 1. 2, 3 ^Q] by which it is articulated to the vpper proceſſe of the ſhoulderblade by the interpoſition of a peculiar griſtle, which *Galen* calleth the ſmall griſtly bone, made ſaith he, for the ſecurity of the ioynt.

TABVLA. XVIII.

See this Tables deſcription, in lib. 6. fol. 393.



The vſe of the Coller-bone is, that the Blade ſhould not together vvith the arm fal vpon the breſt, and ſo many motions of the arme be forfeyted. It is true indeed that theſe bones may ſeeme not to belong vnto the Cheſt, becauſe all brute beaſts haue Cheſtes, but very fewe of them theſe bones. We anſwere, that Nature is moſt Wiſe in her adminiſtrations and hath therefore giuen theſe bones vnto men becauſe they haue hands, which it concerned them much diuerſly to mooue into manie poſitions from one ſide to another. Now becauſe in ſuch flexions the arme ſhould not fall hedlong as it were into the oppoſite ſide; and when it is voluntarily bent or with violence mooued that way, might yet be able to recouer it ſelfe, or to ſtay his fall, therefore the clauicles were ſet betwixt the two ſides to inhibite or preuent any ſuch ouer-extent: againe, were it not for the Clauicles when wee offer to thruſt any thing ſtrongly backeward, the blade would fall forward, as ſometimes the arme falles vpon the ribs when it is luxed or put out of ioynt, or when the blade hangs downe like a wing, as it will do when the Coller-bone is broken. And thus much concerning the Clauicles.

Their vſe.

CHAP.

CHAP. XXV. *Of the Breſt-bone.*

The Names,

THe Breſt-bone is the forepart of the Cheſt, and called in Greek στέρνον, either becauſe [ta.18. fig.9. g h i] it is diſpoſed in the middle of the ribs, or becauſe there is τὸ στέρνον τῆς νῆς *Mentis firmitas*, becauſe the heart lyeth vnder it. *Hippocrates* calleth it στῆθος, the Latins *Pectus* or *os pectoris* the breſt-bone, becauſe it maketh the forepart of the breſt, and ſafegardeth the noble partes therein contained. This Breſt-bone is ſomwhat conuexe or embowed, long alſo or broad, and becauſe it is like the handle of a dagger ſuch as was vſed in olde time, it is called ξυφοειδὴς.

Subſtance.

The ſubſtance of this bone is not ſolid as other Bones are but fungous and reddiſh, compounded alſo of Bones and Griſtles: for it is not one bone, vnleſſe it be in very olde men, otherwiſe if you ſcrape off the membranes, you may ſee it is compacted of many. In Infants new borne it is altogether griſtly excepting the firſt bone of it, a little after ther may be obſerued eight diſtinct partes, each of them diſtinguiſhed from other by a large and thicke Griſtle, ſeauen of which were made to receiue the articulation of the ſeauen true ribs. The eight was framed to be a foundation to the Sword-like Cartilage, which wee properly call the Breſt-blade.

Number of Bones

The firſt.

Theſe Bones after ſeuen yeares are conioyned and begin to grow fewer, yet ſometimes foure may be diſtinguiſhed, that is to ſay, the firſt [ta.18.fig.6 a] which is the broadeſt, the ſecond and the laſt: thoſe betwixt theſe do grow into one, but in growne bodies there are but three, diſtinguiſhed each from other by a tranſuerſe line. The firſt and the laſt both in young and old carry alwayes one forme, but the middlemoſt is diſtinguiſhed into many parts, acording to the youth and age of the party, which parts are griſtle bound or faſtened together with a griſtle betwixt them by *Coalition*. For although according to the motion of the cheſt it ſeeme to be eleuated and againe depreſſed by the helpe of the ribs, yet it hath no motion apart or by it ſelfe. In dogs it conſiſteth alwayes of ſeauen Bones ioyned together by *Synarthroſis* or *Coarticulation*. But we wil follow the deſcription as it is in a man, in whom the Bones are three.

The vppermoſt [Tab.18.fig.6 a b c] is larger and thicker then the reſt, and is like the head or pummell of the handle of a dagger, but flat and vnequall; horned or creſcent aboue [tab.18.fig.9 g] which maketh a kinde of cauity or den which ſome haue called *Iugulum*. In the middeſt for more ſtrength it protuberateth like a triangle [tab.18.fi. 6 a] at which the firſt rib [fig.6 g] is ioyned, a griſtle comming betwixt them. A ſecond griſtle it hath, where the firſt bone is ioyned to the ſecond. [ta.18. fig.6 b] On the inſide about the middeſt it hath a boſome grauen in it [ta.18.fig:7 d] made to giue way to the deſcent of the rough Artery, and other boſomes on each ſide [ta.18.fig, 6 & 7 e f] which receiue the heads of the coller bones.

The ſecond.

The ſecond Bone of the *Sternon* hath on either hand in the ſides many cauities [t.18 fig. 6 k l m n] diſtant one from another vnequally, and it is compared not amiſſe to the haft of a dagger, wherein there are inequalities for the fingers to take faſt hold vpon, for euen ſo theſe impreſsions do receiue the griſtles of the third, fourth, fift & ſixt ribs. This Bone isnarrower then the other two, and in women ſomtimes toward the end perforated with a broad hole much like a heart. [Tab. 18.fig.8 u]

The third.

The third Bone is leſſe but broader then the ſecond [ta.18. fig. 6 and 7 c] wherefore *Celſus* wrote that the Breſt-bone was horned or creſcent at both ends; but you muſt vnderſtand him of a man and not of a dogge. Heereto is ioyned the griſtle of the ſeuenth rib iuſt where it ſelfe is faſtened vnto the ſecond bone, and in ſome bodies it is diuided in the middeſt by a line.

The Griſtles of the Breaſt-bone.

On both ſides this *Sternon* is ſmooth, ſauing that aboue it is ſomewhat exaſperated to giue an originall vnto the muſcle *Maſtoides* or the ſeuenth muſcle of the head. Griſtles it hath, (beſide the two vpper which go betweene the coniunction of it with the Clauicles) one betwixt the firſt and the ſecond bone [ta.18.fig.6, 7 h] which ſupplieth the place or doth the office of a Ligament. Another in the end, long, mooueable, and triangular [t.18.fig.6 & 7 t] which commonly is ſharpned like the point of a ſword, whence it is called ξυφοειδὴς, *Enſiformis* and *Mucronata*, the *Blade of the Breſt*; this alſo is ſometime broad in the end, ſometime byfurcated, and therefore ſome haue called it *Furcella*, the *litle forke*. Oftentimes it is round, ſometimes double, ſaith *Laurentius*, and the leſſer part lyeth vpon the greater, as the leaues of the Herbe called *Horſetoung*: ſometime alſo it is perfora-

ted

ted [ta. 18. fig. 8 *u*] to transmit the Mammary veins which are accompanied with a nerue. If this griſtle (ſaith *Platerus* and *Bauhine* conſenteth with him) bee too much preſſed or curued inward in children, which diſeaſe women call the *Compreſsion of the Heart*, it offendeth the Liuer and the ſtomacke vnder it, and thoſe children die of that kinde of conſumption which we call an *Atrophie*, for in children this griſtle is ſomwhat long, and oftentimes may be felt with the finger. Heere alſo we muſt obſerue that cauitie which the Ancients called καρδία, commonly the *Heart-ſpoone*. The whole breſt in men is ſomwhat eleuated or raiſed vp, but in women it is more flat & depreſſed becauſe they haue greater dugs which would ſtand out too far if the breaſtbone were raiſed as high as it is in men.

The vſe of the breſt-bone is the ſame which we ſhall ſay anon the vſe of the ribs is. The Breſt-blade is a defence to the parts thereunder, that is, the Midriffe & the mouth of the Stomacke; and this may be proued, ſaith *Bauhine*, becauſe if it be compreſſed or rubbed too much, a *Nauſea* or loathing will follow: againe, he that is readie to vomit ſhall find a paine iuſt vnder it. And thus much of the Breſt-bone.

CHAP. XXVI. *Of the Ribbes.*

THE ſides of the Cheſt are called by the Grecians πλευραὶ and σανίδες, becauſe they are placed ſide by ſide like the Rowers in a Galley: the Latines call them *Coſtæ*, wee call them the Ribbes. They are commonly both in Men and in women on each ſide twelue, oftner more then fewer. For nature would rather there ſhould be aboundance then want. And in a publicke Anatomy when a Malefactor was cut vp, *Bauhine* found thirteene on each ſide: the firſt on the left ſide was perfect, but the firſt on the right ſide was imperfect. The Names and Number.

Fallopius alſo twice found one too many, *Columbus* once eleauen at *Padua*. They are diuided into *True* and *Baſtard* Ribs. The true Ribs are the ſeauen vppermoſt [table 18. fig. 9. from Char. 1 to 8] ſo called, becauſe they make a perfect circle being ioyned together by the Spondels of the Backe and the Breaſt-bone. For behinde they are faſtened with ſtrong Ligaments by *Dearticulation* or *Diarthroſis* to the Spondels of the backe. [ta. 18. fig. 10, S T] And that they might ſticke the cloſer the knotte is double, one higher at the body of the Spondell, another lower at his laterall proceſſes: Before, they are articulated to the breſt-bone, [Tab. 18: fig 9 c] for their Cartilages bee like little heads ioyning with the ſmooth boſomes of the *ſternon* by *Synarthroſis* or coarticulation. The two firſt Ribbes are called ἀντίστροφοι, as it were *Retorted*, the two next are called σφαιραὶ, that is, *ſolid*; the three laſt, by *Pollux* hee that gaue them all Names, στερνίδες, that is, Pectorall Ribbes. The true ribs,

The Baſtard Ribs are the fiue lower; they are ſoft and almoſt griſtly, that themſelues might be more ſafe from iniuries, and by them the parts thereunder. And indeed, the prominent parts of Bones were for the moſt part by Nature made griſtles which if it be wounded or violated will not breake but eaſily reunite. Theſe Baſtarde ribs therefore do end into exquiſite griſtles, which are retorted vpward and faſtned one to another [Ta b 18. fig. 19 m] excepting the twelfth, and ſo are ioyned to the griſtles of the true ribbes. [tab. 18. fig. 19, l] The baſtard ribs.

They may alſo be ſayde to be imperfect, becauſe they are onely articulated vnto the Rackebones, but that after diuers manners. For the eight and the ninth haue a double articulation, yet doe their ioynts not ſticke out ſo farre as the ioyntes of the true Ribbes doe, which receiue more ſtrength from the Racke-bones then from the Breaſt-bone. The eleauenth and the twelfth haue onely the vpper articulation, as alſo hath the firſt oftententimes, but the tenth is ioyned ſometimes with a double ioynt, ſometimes with a ſingle.

Theſe Baſtard ribs do not attain vnto the Breſt-bone that the lower belly might better be dilated when the ſtomacke is well ſtuffed or the womb impregnated. The eleuenth ſometime, ſometime alſo the twelfth are faſtned to the Midriffe. Againe, the twelfth is the leaſt of them all, and according to ſome mens eſtimation doth not deſerue the name of a rib, that there might be roome left for the bowels in the lower belly, and becauſe it was ſo little *Galen* calleth the eleuenth Rib the laſt. Sometime this twelfth Rib groweth to the oblique muſcle of the *Abdomen*, ſometime againe it is ſeen to haue a circumſcription of a proper muſcle whereby it is drawne downward.

All theſe ribs are not only of a bony yet fungous ſubſtance, [Table 18. fig. 11 R] but

alſo euery one hath his owne Griſtles, both behinde where they are articulated vnto the Rack-bones; and before where they are commitred to the breſt-bone, [tab. 18. figu. 9 ^a shew the coniunction of the ribs with the griſtles, C D. the coniunction of the Griſtles with the breſt-bone] But the fore-griſtles are greater and thicker, becauſe the fore-part of the cheſt is diſtended and contracted; ſo likewiſe the griſtles of the baſtard ribbes are longer then thoſe of the true ribs, but the griſtles of the true ribs are harder then thoſe of the baſtard ribs, becauſe they were to bee ioyned with the breaſt-bone which is a harder ſubſtance, whereas the griſtles of the baſtard ribs are thin and narrow, becauſe they are ioyned with other Griſtles: & hence it is that ſome Anatomiſts haue called them χόνδρας, that is Griſtles. Notwithſtanding the Griſtles of the firſt and laſt ribs are very ſhort, but that of the laſt is narrow and ſharpe, that of the firſt broad and large. The lower ribbes in men remaine griſtly euen to extreame old age: the vpper ſomewhat before that time do begin to grow bony, and haue, as we may ſay ſafely by *Galens* warrant, bony griſtles. In Virgins after their paps begin to ſwell the griſtles alſo grow ſome-what bony, the better to ſuſtaine the waight of the paps that lye vpon them, whereby if the ribs ſhould bee depreſſed, the motions of the Cheſt would be interrupted.

Their Figure

The figure of the ribs is ſemicircular like a Bow, to make the figure of the cheſt circular and round, whereby it becommeth ſtronger and more capacious. The length of the ribs is not the ſame in all, for the vpper and the lower are the ſhorteſt, the middlemoſt are the longeſt and the broadeſt, excepting the firſt which is the broadeſt and ſhorteſt of all the reſt. Againe, the vpper ribs are more crooked and more bent, the lower are not ſo embowed. All of them in their originall are narrow and ſomewhat round, & by how much they come neerer to the breſt by ſo much do they grow the broader, which broder part is called πλάτη or the Palme, the narrow part which is towardes the ſpine νῶτον, the Rower.

They are alſo thicker aboue then below, and by that ſigne may the right bee diſtinguiſhed from the left. On the outſide eſpecially where they are tyed to the rackebones they are rough [tab. 11. figu. 11 P] and vnequall, that from thence the Ligaments might proceede by which they are faſtned to the Rackes; in that place alſo they haue two protuberations, one whereby [ta. 18. figu. 11 ^L] they are articulated to the ſinus or boſome of the Rack-bone, another where they are ioyned to the tranſuerſe proceſſe. [Tab. 18. fig. 11 ^M] They are alſo exaſperated [Tab. 11. fig. 11 ^o] to receiue that Muſcle of the Cheſt which is called *Sacrolumbus*, accounted by *Veſalius* and *Falopius* for the fourth, by *Columbus* the fift Muſcle of the cheſt, as alſo for the originals and inſertions of the intercoſtal muſcles. On the inſides they are ſmoothe, that they might not hurt the *Pleura*, and in the lower part of euery rib; [tab. 18. fig. 11 ^K] there runneth a ſinus like a canale thoroughout theyr length to receiue three Veſſels, a Veine, an Artery & a Nerue, but the Nerue lyeth next vnto the rib; and theſe ſinus are moſt conſpicuous in the middle of the Ribs, and in that part that is next to the Rack-bones.

Their Vſe.

The vſe of the ribs is to be a defence vnto the breſt, that is, to defend the bowelles therein contained. Moreouer, to yeelde a fit place for the implantation and ſupportation of the Muſcles which ſerue for Reſpiration, that they ſhould not fall down and interrupt the functions of the Heart and the Lungs. Wherefore, that when we breath in & breath out though we be faſt aſleepe, the cheſt might more eaſily follow his neceſſary conſtriction and dilatation, a part of them was made griſtly, which griſtles likewiſe defend the bowels ſeated vnder them, and ſuſtaine ſome Muſcles of the *Abdomen* which otherwiſe would fall inward and impeach the offices of the bowels of the lower belly. And thus much of the Ribs.

CHAP. XXVII. *Of the Shoulder-blades.*

His Names.

THE backpart of the cheſt is called the Shoulder-blade, in Latine *Os Scapulæ*, in Greeke ὠμοπλάτη. [tab. 19. fig. 7, 8, 9] There are two of them, one on each ſide, which behinde ſitteth vpon the top of the Ribbes like a ſhield for their defence, and is articulated with the clauicle and with the arme; for whoſe ſake it was eſpecially created, as well to hold it to the body, as to affoord an originall to many Muſcles by which it is moued. It is faſtned alſo to the ribs, to the nowle and to the bone *Hyois* by the interpoſition or mediation of Muſcles.

The figure of it is after a ſort triangular: on the inſide [ta. 9. fig. 7 ^N] concauous: on the outſide

outside: [ta. 19. figu. 8 V, V] it is prominent, which place is called the Basis, and this basis hath an angle [ta. 19. fig. 7, 8, 9 shew the vpper Angle] and a rib both aboue and belowe, from which is produced a spine that looketh vpward. [Ta. 19. fig. 8 and 9 G H]

Table 19. Is the same with Table 16. a little before in folio 978.

The extremity of this Spine is commonly called ἀκρώμιον, albeit according to *Hippocrates* *Acromion* be the articulation of the clauicle with the vpper part of the blade or a gristlye bone, which like a Ligament tyeth those Bones together.

It hath three processes: the first is the shortest, and hath a short necke which is called *Scapulæ ceruix*, [t. 19. fig. 7, 8 C D] which Necke endeth into a sinnewated or hollowe *Cup* or head, [ta. 19. fig. 7 & 8 [a b]] which *Cup* receiueth the head of the arme, & it is compassed with a thicke gristle [t. 19. fig. 8 [c d]] whereby the *cup* is inlarged, that the heade of the arme should not so easily fall out of ioynt. The second processe is the ende of the spine, of which wee spake euen nowe, which hangeth ouer the ioynt of the arme, called therefore *Acromion*, [t. 19. fig. 7, 8, 9 [e]] the point of the shoulder and the top of the shoulder, and by this processe the shoulder-blade is ioyned with the clauicle. The third processe is the least, and on the inside [ta. 19. fig. 7 & 8, [f]] which is called σιγμοειδὴς, and from the likenesse it hath with an Anchor ἀγκυροειδὴς. Some call it *Coracoides*, because it is like the Beake of a Crow, and this processe holdeth the bone of the arme in his seat. Processes 3.

It hath fiue Appendices, three are at the inside and at the basis, and affoorde an originall to some Muscles: [ta. 19. fig. 7, 8, 9 [x y]] the other two do breed Ligaments which ioyn the arme to the head of the blade, and the clauicle to his second processe which wee called *Acromion*. Appendices 5

It hath also two cauities, one aboue the Spine, and another belowe it, called *Interscapilum*. Cauities 2.

Finally, there is an inequality in this Bone; for in the middest it is very thinne, in the processes thicke, medullous and fungous. It hath also perforations which admit Veines and Arteries for his nourishment. And thus much of the shoulder-blades.

CHAP. XXVIII. *Of the Hip, Haunch and Share bones.*

THe third part of the Trunke was saide to be the Bone without a name, so called first by *Oribatius*, some from the greater part called it the Hanch-bone: *Rufus* ἰσχίον, *os Coxæ*. [t. 20. f. 12, 13, & 14] It appeareth to be one on each side, because the gristles are dryed vp, but in children till the seauenth yeare of theyr age it is found to be made of three Bones diuided by gristles, and therefore they are saide commonly to be on each side three bones.

The vpper and broader parts which are ioyned with the Holy-bone [tab. 20. fig. 13, [a b cc dd]] are called *ossa λαγόνων*, in Latine *Ilium*, in English the *Haunch-bone* [ta. 16. fig. 1 [mm] ta. 20. fi. 13 aboue [r] to [f]] Their semicircular circumference is called the Spine of the haunch-bone, [ta. 16. fig. 1 & 2. [ii] ta. 20. fig. 13 [klmn]] which is vnequall, that some muscles might take their original therfrom, to wit, the oblique ascendent of the *Abdomen*, the fift of the chest, the first bender of the Leg, and the first extender called *Membranosus*. The inner part of the circumference is called *Costa* or the rib: the vtter part of the whole bone [Ta. 20. f. 14 at X] is called *Dorsum Ilij* the backe of the Haunch-bone, wherein there are vnequal inscriptions or lines for the three muscles of the Thigh which make the Buttockes. The Haunch-bone,

The interiour part is hollow and broad to affoord a fit and conuenient position to the internall Iliacke Muscles: [ta. 20. fig. 13, KK] aboue also it extuberateth for the Square muscle of the backe that is the first, and below for the tenth of the thigh.

The lower and vtter parts of this bone are called *ossa Coxendicis*, [ta. 16. fig. 1 [nn]. Tab. 20. fig. 13, below [r] & [f] as farre as to [xy]] in which there is a great sinus which they cal *Acetabulum* and *Pixidem* [ta. 20. fig. 12 and 14 [abc]] the *Cup*, and properly in our English Tongue the *Hip*, to which the head of the thigh is articulated exceeding strongly. This *cup* or Hip hath a gristly processe, [ta. 20. fig. 12 and 14 [c]] called *Supercilium* or the brow, in vvhose circumference there are obserued three bosomes, two protuberations, [ta. 20. figu. 12 and and 13, T, V] an acute processe, [ta. 20. fig. 13 & 14, [g]] and finally an Appendix [ta. 20. fi. 13 and 14 [i]] that is very thicke: all these were ordained for the production partly of Ligaments, partly of muscles.

Finally, the foure parts of this vnnamed Bone are called *ossa ὄνβης*, *Pubis*, in English the Share-bones, [ta. 16. fig. 1 and 2, [pp]. Ta. 20. fig. 13 and 14, that which is below R and Φ] The share-bones.

From T to *f* in Fig.13, & 14, A part of the *Coxendix* called *Os Illium* the *haunch*-bone, that which is below as far as to R & φ is called by the name of *Coxendix* the Hip the remainder is the *sharebone*.

A B CC DD 13, the foreside of the hanch bone where it is ioyned to the Holy-bone distinguished by a protuberation CC into two *sinus* A B DD.

E F G 13, the backside of the hanchbone which gapeth from the Holy bone, & is filled vp by a gristle,

H 13,14, a part of the backside reaching out beyonde the processe of the Holy-bone.

K 13, An impression in the inside of the hanch-bone made for the originall of of the fist muscle of the back.

L 12,13. the inside of the *appendix* of the *hanch bone*.

M 12, the *anterior* end of the *appendix*.

N 13,14, his *posterior* end.

O 12,14, the outside of this *appendix*.

P Q R 13. A swelling from whence the tenth muscle of the thigh issueth.

* 13, this place affoordeth an originall to the 7. muscle of the thigh

S 12,13,14, the vpper *sinus* of the *Coxendix* aboue which do run the sixt muscle of the thigh, & the 7. with a Nerue,

T 12,13,14, A higher protuberation aboue this *sinus* or cauity.

V 12,13,14, another lower protuberation.

X Y Y 14, a darke line in the backe of the haunch bone X, another in the same place Y Y.

Y 12,13, the vpper *sinus* of the sharebone

a b 12,13, The *Cup* of the *Coxendix* which admitteth the head of the Thigh, the deepe hollownesse of it is marked with *c*. *d* 14, the *sinus* or bosome wherein the *Cup* is grauen. *e* 12,14, the brow of the *Cup*. *f* 13,14, a cauity of the *Coxendix* made for transmission of the fourth nerue of the Leg. *g* 13,14, the acute processe of the *Coxendix*. *b* 12,13,14, a *sinus* to which the tenth muscle of the thigh is reflected. *i* 12,14 the Appendix of the *Coxendix*, *k l m n* 14, diuers impressions in this appendix. *o* 14, the *posterior* end of this Appendix. *p* 12, P 14, the roughnesse of the share-bone to which the gristle groweth. *q* 12,13,14, the hole of the share-bone. *s* 12,13,14, a bosom aboue the hole of the sharebone. *t* 12,13,24, the lower processe of the sharebone.

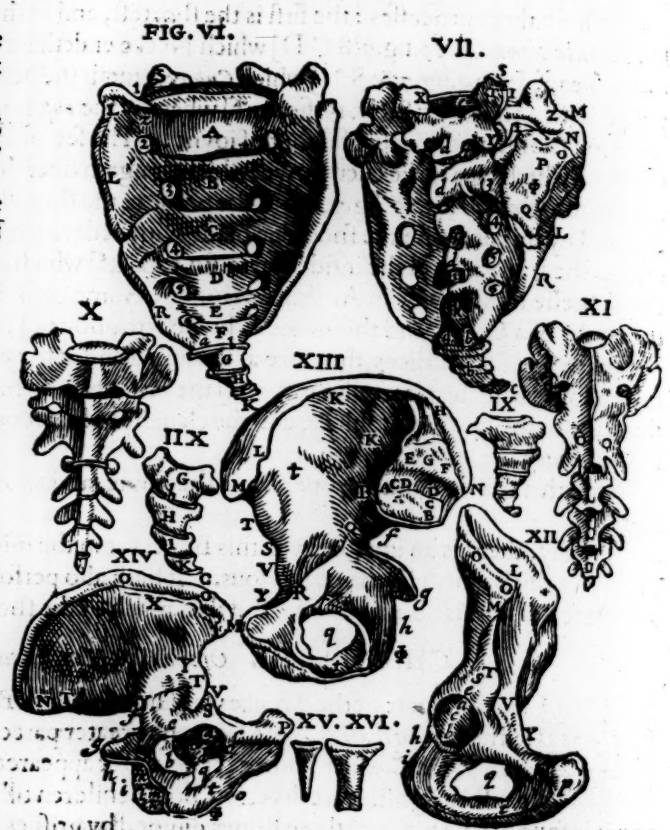
Figure 12. sheweth the forepart of the Coxendix which is ioyned to the right side of the Holy-bone.

Fig. 13. the inside of the Coxendix. Fig. 14. his outside.

Fig. 15. the gristle that goeth betwixt the share-bone in a man

Fig. 16. the gristle that goeth betwixt them in a woman.

TABVLA XX.



because in the middle of the share they are ioyned together by a gristle. [t. 20. fig. 15. at 6] Before and aboue they haue a *sinus* or bosom, [ta. 20. fig. 12. ʏ] made for the descent of the crurall vessell: they are also rough for the originall of the right and pyramidall muscles of the *Abdomen*, and of the second bender of the Leg. But otherwise they are but thinne bones and perforated with the greatest hole that is in the whole body [ta. 16. fig. 1, and 2, ϥϥ tab. 20, fig, 12, 13, and 14, ϡ] This hole was made for lightnesse, and the empty place is stopped vp on the outside with the external *obturator* or compassing muscle of the thigh and on the inside with the internall, vnder the hole it hath a processe [ta, 20, fig, 13, 14, ϡ] from whence the bodies of the yard and some muscles take their originall.

Their vse. These Bones ioyned with the Holy-bone doe make that cauity which they call the *Bason* [tab, 16. fig, 1, sheweth it] which contayneth a part of the Guts, the Bladder and the Wombe: and to conclude, these three bones put together make the *basis* or foundation of the body, which it selfe is immouable whilest all the body moueth vpon it. And thus much of the Trunke.

CHAP.

CHAP. XXIX. *Of the Bones of the Arme and the Cubit.*

WE haue gone through the two firſt parts of the *Sceleton*, that is, the Head and the Trunke; the third remayneth which comprehendeth the Ioynts. Theſe Ioynts are two, the Hands and the Feete. The Hand we call all that which is betwixt the ſhoulder-blade and the Fingers; and is deuided into three parts, the Arme, the Cubit & the Hand properly ſo called, of which we will ſpeake in their order, and then deſcend vnto the Foote.

The Arme is called by the Greekes βραχίων, by *Celſus Humerus*, commonly *brachium*. It is but one bone [tab. 21. fig. 1, & 2,] round and vnequall, long alſo and the greateſt of all the bones of the hand, yea of the whole body except the Thigh-bone if we beleeue *Galen*. But *Columbus* ſayth that it is not ſo bigge as the Holy-bone, nor ſo broade as the Hanch-bone, nor longer then the Leg-bone. It is articulated to the ſhoulder-blade and the cubit, and for theſe articulations both the endes of it are protuberated or ſwell into heades. For in the vpper part where it is inſerted into the *Cup* of the Blade, and articulated by that kinde of *dearticulation* which we called *inarticulation* it hath an Appendixe [table. 21, figu, 1.[A B F H]] which maketh the head of the Arme or the *Acromion* ſeated in the vpper but inner parts. The names of the arme. One bone.

This head is large and orbicular, and cruſted ouer with a griſtle [ta. 21, fig, 1, & 2, [A B C]] that it might better bee turned in all motions within the cauity of the *Cup* of blade, which alſo is enlarged for that purpoſe with a plentifull griſtle. At the outſide of this head do bunch out two proceſſes rough and vnequall, whereout doe ariſe the ſtrong Ligaments which tye the Arme to the blade. The firſt of theſe is ſeated on the foreſide [fig. 1, [D]] the other and the greater on the backeſide [figu, 1, & 2, [E]] and the greateſt part of them both is contayned in the Appendix.

It hath two *Sinus* or boſomes, one orbicular and rough at the ſide of the head which it diſtinguiſheth from the proceſſes [tab. 21. figu. 1, [F G]] to which a Ligament is implanted. The other is on the outſide and long, running downward [fi, 1, H I] betwixt the two proceſſes which it doeth diſtinguiſh or ſeparate. And this *ſinus* was grauen for the beginning of the bending muſcle of the cubit which is called *Biceps*, and groweth out of the *cup* of the ſhoulder-blade, for through this *ſinus* as through a pulley that muſcle doth runne. 2. Sinus.

The lower part of the Arme which at the Cubit is articulated to the Ell & the Wand, is in Infants increaſed by an Appendix, which in proceſſe of time is ſo vnited to the bones that there remayneth no footſtep, no remembrance of the appendix. This lower part is broad and the figure of it diuers, for it is partly protuberated and partly excauated or hollowed.

The protuberations or proceſſes are two very notable on each hand, and one at the ſides of the orbe, becauſe it was to be articulated to two bones. The exterior of theſe [ta. 21, fig, 1, [P]] is the thicker, and endeth into a head cruſted ouer with a griſtle which entereth into the vpper *ſinus* or cauity of the Wand. It is ſituate before, and is made round to turne the Wand vpward and downward. This proceſſe at the outſide buncheth out very farre, that from thence ſome muſcles might take their originall [fig. 1. vnder [Q]] and endeth into an vnequall Line. Betwixt the heade and the protuberation there is a *ſinus* on the backeſide [fig. 2. [R]] grauen, to conuay the fourth nerue that paſſeth vnto the hand. The proceſſes.

The inner proceſſe [[S]] which may eaſily be felt euen in liuing bodies, & ſwelleth much inward to yeilde a place for the originall of ſome muſcles, is likewiſe cruſted ouer with a griſtle. Neare the ſide of the orbe it hath two *ſinus* or cauities, one ſhallow in the foreſide [figu 1. [T]] to leade along the third nerue that paſſeth vnto the Hand; the other in the backeſide [fig. 2. [V]] through which the fift nerue is conuayed. Betwixt theſe two *ſinus* wee meet with an orb, which ſayth *Falopius* may by a curious Anatomiſt bee called a third apdix. *Archangelus* calleth it a third and middle proceſſe.

It is alſo called *trochlea* or the pulley whereto the Ell is articulated by *gynglimos*, and it is moued onely with a right motion: this orbe becauſe it hath a cauity in the middeſt [[X]] and buncheth out on either ſide [[LM]] ſeemeth to be like the gutture of a pulley wherein the cord doeth ſlip, and therefore it is commonly called *Humeri rotula* the gutture of the Arme. [[KLM]] That part of this cauity which is like a pulley was at the firſt an Appendix, yea betwixt the two proceſſes there went a griſtle which after the ſeuenth yeare groweth bony, and maketh a part of the cauity and the outward browe thereof. In the vpper part

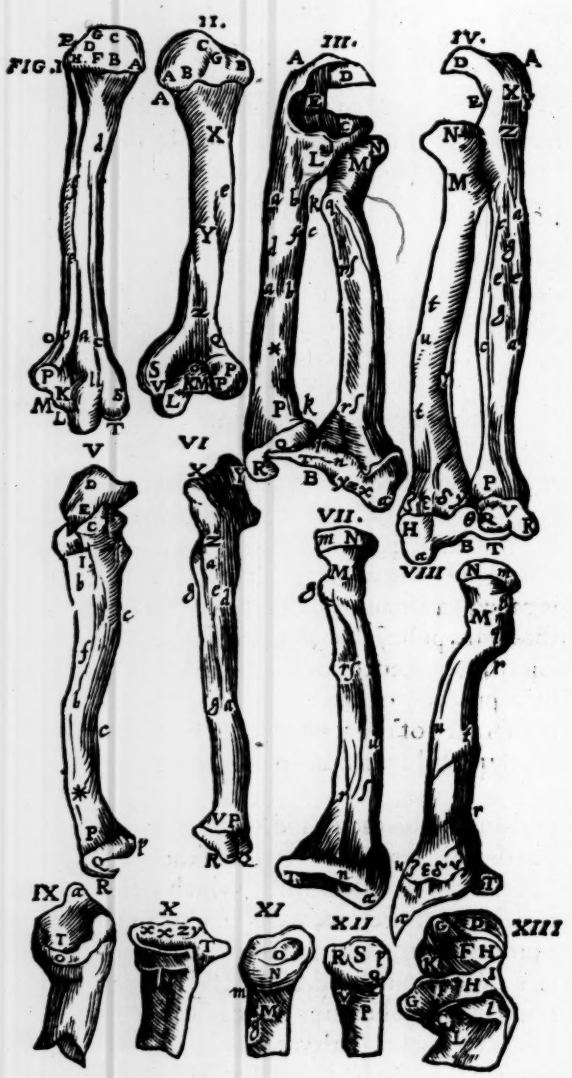
TABVLA XXI.



A,B,C,1,2. The head of the arme which entreth into the cauity of the shoulderblade
D 1, His anterior processe.
E 1,2. The other posterior processe.
F G,1,2. the orbicular cauity of the head thereof.
H,I,1. A right sinus leading directly downeward.
K 1,2, the sinus of the gutture of the arme which receiueth the cubit.
L,M,1,2, the two lips of the gutture, the inner and the vtter.
N,I, 1,2, the anterior sinus in the vpper part of the guttur.
O 2, Another posterior sinus.
P,1,2, the head of the arm to which the wand is articulated.
Q 1,2, A line swelling out in the vtter side of the arme.
R 2. A bosome of the vtter proces of the arme
S 1,2. the inner protuberation of the Arme.
T 1, the anterior sinus of the inner protuberation.
V,6. the posterior sinus of the same,
X,Z 2 the length of the arme betwixt his thick ends.
Y 1, the middle part, where the bone of the arme is as it were writhen.
a 1, A bunching line in the fore-side, which runneth along as farre as to *f*.
b,*c*,1. Impressions on both sides the line.
d 1, the vpper gibbous part of the Arme.
e,1,2 A roughnesse in the outside of the middle of the arme.
f 1. Another somewhat higher, but more inward.

Fig. 3,4,5,6,7,8,9,10,11,12,13.

A 3,4. The vpper part of the Cubit, whereby it is ioyned to the arme.
B,3,4. The lower part of the cubite reaching to the wrest.
C 3,5,13, the anterior and vpper processe of the Ell.
D,3,4,5,13. the posterior and vpper processe of the Ell.
E,3,4,5. A sinus of the Ell, receiuing the *pulley* of the arme.
F,13. A protuberation in the foresaide sinus.
GG,HH,13. The internal side depressed nere vnto the protuberation at G. the external side at H.
I,13, A sharpe small cauity in the left hand, to which the right aunsweres on the other side. L,3,5, 13, An saperity in the roote of the processe of the Ell. M,3,4,7,8,11, the Necke of the Wand. O 11, A sinus of the wand wherein the head of the arme doth enter. P 3,4,5,6,12, the necke of the Ell. Q,3,4,5,6,12, the appendix of the Ell. R,3,4,5,6,12 the processe of the Ell called *Styloides*. S 12, A sinus or cauity in the basis of the appendix of the Ell. T 3,4,7,8,9,10, a Gristle growing to this sinus. V 4,6, a sinus in the side of the appendix of the Ell. *X*,Y,Z,4,6 three corners of the latter processe of the Ell. *aa* 3,4. a line or the first bunching part of the Ell. *bb* 3,5, the second line of the Ell. * An oblique inferiour line of the Ell. *cc*, 3 4,5. the sharpnesse of the Ell touching the wand. *dd* 3,6 the first vtter side of the Ell. *e* 4,6, the 2 vtter side. *f* 3 5, the lower rough side. *gg* 4,6 a line drawn in the vtter side *h*,*i* 1,3, the commissure of the wand with the ell aboue *h* and below *i*. *ik*,3 A distance where these bones do part asunder. *l*, 13, A sinus of the ell wherein the head of the Wand is turned. *m*,7,8,11 the head of the wand, resting vpon the *sinus* of the *Ell l*. *n*,3,7, the lower appendix of the wande. *o* 9, A Sinus of the *Radius* receiuing the head of the *Ell*. *p*,5,12, the head of the *Ell* entering into the Sinus of the wand *o*. *qq*, 3,4,7,8 11. A roughnesse swelling vnder the necke of the wand. *rr*, 3,4,7,8. An acute line respecting the *Ell* & the wand. *ſſ* 3,7, the rough internall side of the Wand. *tt*, 4,8 the smooth externall side of the wand. *u*,4,7, 8, A roughnesse in the midst of the length of the wand. *xy* 3,10, a Sinus of the wand whereunto the wrest is ioyned. *z* 3,10, a protuberation in the midst of the Sinus. *α* 3,7,8,9,10, the processe of the Sinus x. *ββ*, 4,8, the inner Sinus of the wand double which carieth the tendons. *ζ* 4,8, the externall double Sinus of the Wand. *η* 4,8, the 4th Sinus producing a Ligament. *θ* 4, A Sinus of the wand common with the *Ell*.

of the Orbe there are grauen two cauities or boſomes, which *Hippocrates* called βαθμίδας, diſtinguiſhed onely by a ſcale: one of theſe is in the forepart, [fig.1 N] the other which is the larger and the deeper [fig.2 O] is in the backpart, and theſe two are the limites of the motion of the Ell. Moreouer this bone throughout his length is rounde in the middeſt, [fig.1 b] in the ſides a little compreſſed, [fig: 1 *a c*] behinde yet more depreſſed, wherein there is a ſhallow gutture [fig: 2 Y] whereunto the fourth Nerue of the arme creepeth; before, there is a double aſperity or roughneſſe, one [fig: 12 c] made for the ſtronger implantation of the muſcles that mooue the arme, and for the originall of the muſcle which is called *Brachiæus*. In old men the roughneſſe is ſo great that from thence there ſeemeth a proceſſe to grow, whereunto the muſcle called *Deltois* is inſerted. The other *Aſperitie*, [figure. 1, f] is that whereto the fleſhy part of the Double-headed Muſcle dooth grow.

It hath alſo ſmall perforations nere the browes of the head and the boſomes, through which ſome Ligaments are produced or implanted; and moreouer ſome other perforations it hath on the inſide of the length of the bones which admit certaine veines. Finally, the bone of the arme is on the inſide hollowed with a deepe boſome or cauitie, as wel to containe the Marrowe which is his Nouriſhment, as alſo to make the Bone the lighter. Perforations.

The ſecond part of the hand in the large acceptation is called the Cubit, and is ſeated betwixt the Arme and the wreſt, with both which it is articulated. It conſiſteth of two bones lying one vpon another, and faſtened together with a Membranous Ligament. Theſe bones are long, but yet ſhorter then the bone of the arme, and they haue appendices at either ends. The Cubite.

The lower of theſe [fig.3,4 A B 5,6] which is alſo the greater, hath for the moſt part the name of the whole and is called *Cubitus*, yet to put a difference it is alſo called *Vlna* the *Ell*, and ſometime *focile maius*, and is articulated to the ſinus [Figu.2 K LM] which is in the guttur of the arme by *Ginglymos*, and by this articulation both flexion and extention is made. The Ell,

It hath in the vpper part two notable proceſſes, long and as it were triangular, but the angles are obtuſe or dull, and theſe proceſſes together with the cauity in the midſt, which is called *Sigmoides*, are in yong infants griſtly, yet the anterior proceſſe ſtogether with the cauity do quickly become bones, and the marke of the appendix is obliterated. The Poſterior proceſſe beginneth not to harden till after the ſeuenth yeare, and then it is agglutinated or faſtened to the reſt of the bone. His proceſſes.

The Anterior and vpper of theſe [fig.3,5,13 C] entreth into the Sinus or cauity of the Arme, [Fig.1 N] and is cruſted ouer with a griſtle on the inſide: the poſterior [D] is the thicker and the larger, which *Hippocrates* calleth ὠγκῶνα, *Galen* ὠλέκρανον, the Latines call it *Gibberum*, and we the *Elbow*; it entereth into the poſterior cauity of the arme. [figur. 2 O] The places of both theſe proceſſes are rough, [Fig. 13, C D] partly that the Ligaments might more ſtrongly encompaſſe the ioynt, partly for the inſertion of ſome muſcles of the cubit partly alſo to giue originall vnto the muſcles that bend the Fingers; for which cauſe alſo the bone is rough at the roote of the proceſſe: [Figu.5 and 13 L] the circumference alſo of the Sinus or cauity is rough [Fig.13 I K] that from thence Ligaments might yſſue, for in the middle of theſe proceſſes there is a great Sinus [Fig.3,5 * betwixte C D] which receyueth the gutture of the arme. This ſinus is hollowed like a ſemi-circle, and being concluded or cloſed vp by theſe ſwelling proceſſes, repreſenteth the forme of the Greeke *Sigma C.* and therefore by *Galen* is called σιγμοειδὴ, and is cruſted alſo ouer with a Griſtle. But becauſe it might be fitted exactly to the gutture of the arme, it hath in the middeſt an obtuſe protuberation, [Fig.13 betweene FF] and at the ſides on either hande is compreſſed, [fig.13 GG,HH] ſo that it may be compared to a cord compaſsing the gutter or rim of a wheele, that in it the cubit may be bent and extended: and from it is ſeparated by a ſwelling line, leaſt the Ell ſhould ſlippe this way or that way: hence comes the mutuall ingreſſe of the bones one into another, which kinde of articulation is called *Ginglymos*, which we know not how better to expreſſe, then as the crookes of a paire of Hinges do receiue and are receyued one of another. There is yet another Sinus at his outſide ſmooth and cruſted ouer with a griſtle, [fig.5, and 13, I] which receyueth the heade of the *Radius* or Wand. [fig.7,11 m] The Elbow.

From hence the Ell deſcending growes ſlenderer by degrees, [fig:3, from A to B] and at the

the wreſt is encreaſed with a ſmall necke. [fig. 3,4,5,6,12 ᵖ] It hath alſo a round Appendix or an obtuſe head inclining inward, [fig.3,4,5,6,12 ᵠ] about which the Wande is led vpward and downward. Finally it determineth into an acute proceſſe, [R in the ſame figures] which is called *Styloides*, becauſe it is like a probe or writing pen which the Ancients were wont to vſe, not much vnlike a long Bodkin; and from this Bodkin there groweth a Ligament which firmeth or faſteneth the ioynt of the wreſt with the Ell. At the baſis alſo of this appendix there is grauen another vnequall ſinus [Figu.12 S] which diſtinguiſheth the Appendix of the Ell from the wreſt, and to it there is adioyned a griſtle which is placed betwixt this articulation; [fig.3,4,7,8,9,10 ʳ] another ſinus ſomwhat long is grauen on the outſide betwixt the two protuberations, fig.4,6,12 V] to guide & direct the tendon of the firſt muſcle that extendeth the wreſt. [T]

The Forme of the Bone.

Furthermore, the Ell on the lower ſide vpon which it reſteth when we lean, is gibbous a good way, [Fig.6. X Y Z] and beſide there are foure ſwelling lines which run throughout his length made for the vſe of the muſcles of the wreſt. The firſt [fig.4 & 6 from z by *a* and fig.1 *aa*] The ſecond ariſeth or ſwelleth more toward the wreſt [fig.3, 5,6 ᵗ] for the originall of the Square muſcle. The third is the ſharpeſt and the rougheſt [fig.3,4,5 ᶜᶜ] that from thence might ariſe a Ligament which like a membrane faſteneth together the Ell and the Wand. The fourth is prominent indeede but obtuſe or blunt, [fig.4 & 6 ᵍᵍ] from which three muſcles haue their originall.

His vſe

The vſe of the Ell is, that the Hand without danger might bee mooued outward, and againe with facility returne inward.

The other bone of the Cubit which is the vpper and the ſhorter, and occupyeth almoſt the whole exterior part of the cubit, fig.7 and 8] is called ᾿ωλένη, by ſome *Focile minus*, in Latine *Radius*, in Engliſh the *Wand*. This bone in reſpect of the Ell is oblique, and is committed or ioyned thereto aboue and below, [fig.3 ʰⁱ] ſo that aboue the Ell receyueth the wand, below the wand receyueth the Ell; but in the middeſt they ſtand off one from another a good diſtance, [fig.3 ᵏᵏ] partly that the wand might more readily be moued vpward and downward, partly that a place might be made for the muſcles which extend the Cubit.

The Radius or Wand.

This wand is articulated to the arme *per Diarthroſin*, by *Dearticulation*, hauing an oblique and ſlender necke; [fig.7,8,11 ᴺ] a round and depreſſed head, [fi.7,8,11 N] cruſted ouer with a griſtle for more agility of motion, but where it regardeth the arme it hath a round or ſuperficiary boſome [fig.11 O] into which the head of the arme entreth, [fig.1. ᵖ] and at this head the VVand when the Ell is at reſt is turned downward and vpward. A little aboue the necke it hath a rugged and abrupt proceſſe or protuberation [fig.3,4,7,8 11 ᵠ] into which is inſerted the tendon of the anterior muſcle that bendeth the Cubit: ſo alſo through his length there runneth an acute and bunching line [figu:3,4,7,8, ʳ] vnto which is faſtned a Ligament that ioyneth the Ell and the wand together, on eyther ſide with which line the bone is compreſſed [F.3,7,*f*,*f*. and fig.4,8ᵗᵗ] to giue way to the Muſcles. The bone alſo it ſelfe throughout the middeſt of his length is rough, [figu.4,7,8, ᵘ] ſo made for the inſertion of two muſcles of the wand. This wand below at the wreſt is dilated, and groweth thicker, becauſe of a boſome therein to be made for the articulation of the wreſt with the cubit.

It alſo hath an Appendix [fig.3,7 ⁿ] with a double boſom cruſted ouer with a Griſtle, [fig.5,12 ᵒ] that therein the head [fig.5,12 ᵖ] of the appendix of the Ell which is alſo couered with a Criſtle might be mooued. This boſome or cauity was made double [fig.3, 10 ˣʸ] becauſe there are two bones of the wreſt articulated therewith, to wit, the firſt and the ſecond: [ta.22.fig.1,2,4.5, char.1,2] alſo where theſe two are ioyned together, the ſinus protuberateth moderately in the middeſt, [Fig.3,10 ᶻ] yet beſide that protuberation it hath alſo a proceſſe. [fig.3,7,9,10 ᵃ]

His Appendances.

The outſide of the Appendixe of the wand, as alſo of the wreſt is gibbous, and therein hath foure ſinus inſculped or grauen, [fig.4 ᵞ,ᵟ,ᵋ,ᶻ,ʰ] thorough which the tendons of the muſcles might be more certainly conducted through the annular Ligaments. The fourth of theſe [ʰ] is very ſhallow but rough, for it bringeth foorth a tranſuerſe Ligament and beſide ſwelleth vpward, for into that ſwelling the tendon of the Long muſcle which turneth the wand vpward is infixed.

The Sinus.

There is alſo in the ſame place another ſinus common to the Ell and the wand [Fig. 4 ᶿ] made for the Tendon of the muſcle that extendeth the little Finger. [ſ]

Both

Both theſe bones of the Cubit are of a ſolide and hard ſubſtance excepting their Appendances, and full of ſmal holes bored alſo to containe marrow, but if you conſider them apart they are one contrary to another in reſpect of their parts, for the vpper part of the Ell is the thicker the lower is the thinner, contrariwiſe the vpper part of the VVand is the thinner & the lower is the thicker. Finally, the vſe of the wand is to moue the Hand downward and vpward, as alſo in compaſſe, although the Ell, ſaith *Archangelus*, be not moued. The conſtſtence of the bones of the cubit.

CHAP. XXX. *Of the Bones of the Hand properly ſo called, that is, of the Wreſt and After-wreſt.*

THE Bones of the Hand doe follow in the next place which are of foure ſortes: firſt thoſe of the Wreſt; ſecondly thoſe of the Afterwreſt; thirdly the bones of the Fingers; fourthly the Seede-bones called *Seſamina*. The wreſt.

The Wreſt is called in Greeke καρπὸς, in Latine properly by *Celſus brachiale*, but the Greek word is alſo among the Latines grown into vſe, which is *carpus*, wee call it the Wreſt, which is that part of the Hand which is articulated to the Cubite and to the After-wreſt, and is conſtrued or made of eight bones; moſt Anatomiſtes ſay of ſeauen, but becauſe the firſt is thought to bee double, therefore ſayth *Archangelus* we account eight. 8. bones.

Theſe bones are diſtinguiſhed in a double order, the reaſon was that the Hand might be moued with more agility. [ta.22.fig.3,char.5,6,] Theſe eight bones do differ in their magnitude, forme, ſituation and conſiſtence, and in the firſt generation are all griſtles and not bones, but in proceſſe of time they become hard and grow bony. Their ſubſtance is ſpongy as are all the reſt of the bones which of griſtles become bony, of which kinde are all Appendices, the bones of the breaſt and ſuch like. Theſe bones are not without marrow, and beſide are couered ouer with griſtly and ſtrong Ligaments, whereby they are ſo compacted together, but the vpper more then the lower, that if you doe not deuide the Ligaments and the Membranes alſo, you will thinke that they are but one bone, which hath deceiued ſome Anatomiſts.

They haue a double *ſuperficies*, the one *exterior* and gibbous [fig,4] the other *interior* and ſinuated or concauous, [figu,3] and aboue, where they are ioyned to the Cubit, as alſo below where they are articulated with the After-wreſt they are all ſmooth and cruſted ouer with a griſtle, but beſide that griſtle where they touch one another they haue alſo *ſinus* or cauities and heades cruſted with a ſlippery griſtle: and this articulation of theſe bones is to be referred to that third kinde which *Galen* calleth *Neutrall* and doubtfull; for in reſpect of their compoſition it may be called *Dearticulation*, and in reſpect of their pure motion it may bee called *Coarticulation*. Foure of theſe are repoſed in the vpper ranke of the wreſt which is next vnto the Cubit, [tab,22,figur,1,2,3,4,char.1,2,3,4] the other foure in the lower ranke. [chara,5,6,7,8] But becauſe theſe bones want proper names, therefore they are diſtinguiſhed onely by their order and number. their ſurface. Their articulation.

VVe call that the firſt which maketh the inſide of the vpper ranke. It is a long bone curued inward and articulated to the VVand together with the ſecond bone of the latter ranke, and his head entreth into a *ſinus* of the ſecond bone on the inſide. Another head it hath alſo which is greater then the former and lower, and entreth before, into a *ſinus* formed by the fift and ſixt bones. It hath alſo a notable *ſinus*, wherein together with the ſecond bone it admitteth on the inſide the head of the ſeauenth bone. The firſt bone of the wreſt.

The ſecond bone of the wreſt leaneth vnto the former and is leſſe then it: it is repoſed behind in a *ſinus* inſculped in the appendix of the VVand, [tab,21,fig.3,10,] and is ioyned on the foreſide with the firſt bone, below with the ſeauenth, behind with the third hauing a plaine *ſuperficies*.

The third is ioyned with a plaine *ſuperficies* alſo to the Ell and his griſtle: [ta,21,figu,3,4,7,8,] againe to the ſecond and the fourth; and below it hath a large head which entreth into a *ſinus* of the eight bone.

The fourth bone is called *Os rectum* the Right-bone, and is the hardeſt and the leaſt of al the reſt, and almoſt round, for it is neither hollowed nor protuberated as the reſt are. It is ioyned with a depreſſed head to the externall ſide of the third bone, and ſeemeth alſo to be a little inſerted into the proceſſe of the eight bone; otherwiſe it toucheth no bone of that ranke, but in the vpper part thereof the Tendon of the muſcle that bendeth the wreſt is inſerted: below, two muſcles haue their originall which goe into the little Finger.

The

Table 22. Fig. 1. & 2. The first sheweth the inside of the bones of the Hand, the second the outside.
Figure. 3. & 4. shew the inside and outside of the bones of the wrest.
Fig. 5. The posterior part of the bones of the wrest articulated to the Cubit.
Fig. 6. their anterior part ioyned to the Afterwrest.
Fig. 7. Two bones making the first Ioynt of the Fingers.
Fig. 8. The second Ioynt.
Fig. 9. The third Ioynt.

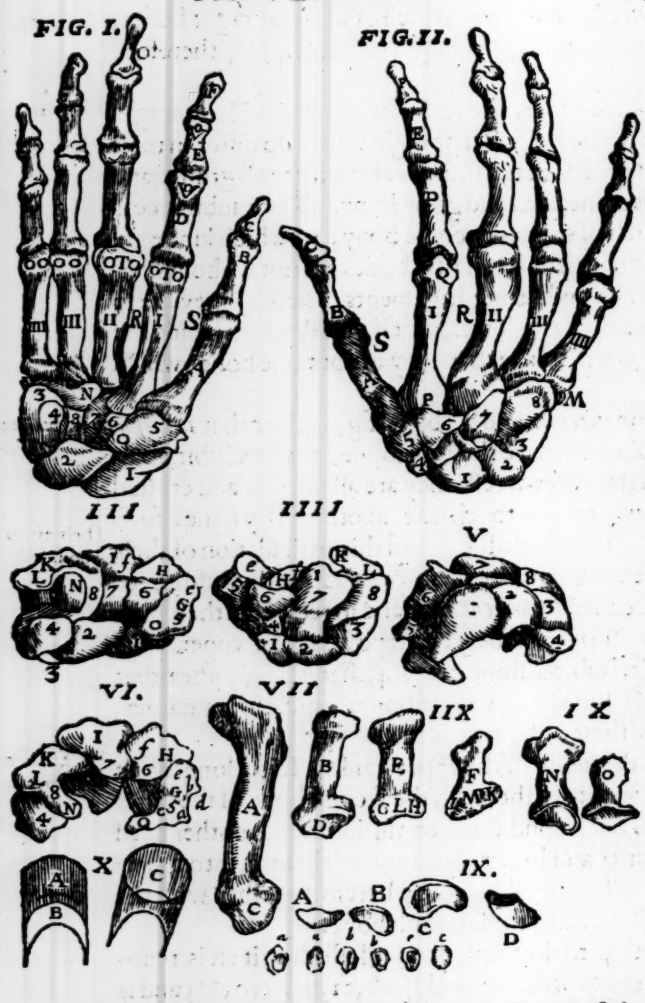
TABVLA XXII.



A 1,2, The first bone of the Afterwrest supporting the thumbe.
I,II,III,IIII, The foure other bones of the Afterwrest ioyned to the fingers.
B C 1,2, the two bones of the thumbe.
D E F 1,2, the three bones of the fore-finger, the same also in the rest of the Fingers.
G 3,6, The gutture of the fist bone of the wrest whereto the first bone of the Afterwrest is articulated.
a b 6, the length of this gutture
c d 6, The inside of the gutture *c*, the outside *d*.
e 3,4,6, A *sinus* at the gutture which the second bone of the Afterwrest doth touch
H 3,4,6, The *sinus* of the sixt bone of the wrest whereto the second bone of the Afterwrest is ioyned.
f 3,4,6, A part of this *sinus* which the third bone of the Afterwrest scarce toucheth.
I 3,4,6, the *sinus* of the seuenth bone of the wrest to which the third bone of the afterwrest is ioyned.
K 3,4,6, The place of the eight bone of the wrest which admitteth the fourth bone of the Afterwrest.
L 3,4,6, a *sinus* of the same bone receiuing the fist bone of the Afterwrest.
M 1,2, a small bone placed sometimes outwardly at the ioynt of the eight bone of the wrest.
N 1,3,6, a processe of the same eight bone swelling out into the ball of the hand.
O 1,3,6, the processe of the fist bone of the wrest from whence groweth a Ligament
P 2, an Appendix of the wrest wherby they are ioyned to the Afterwrest.
Q 2, Another Appendix which with the head entreth into the *sinus* of the fingers.
R 1,2, the distance betwixt the bones of the Afterwrest.
S 1,2, two Seed-bones set at the inside and outside of the first ioynt.
T 1,2, two Seed bones in the first ioynts of the foure fingers.
V V 1, one Seedebone in the second and 3. ioynts of the fingers.
Char. 1,2,3,4,5,6,7,8, these numbers in six figures doe shew the eight bones of the wrest.

Fig. 7,8,9.

A 7, the bone of the Afterwrest which supporteth the fore finger.
B 7, The first bone of Fore finger. C 7, the round head of the bone of the Afterwrest. D 7, a *sinus* of the Fore finger receiuing the foresaid head. E F 8, the first bone of the Fore finger E, the second F. G H 8 two small heads of the first bone of the Fore finger. I K 8, two *sinus* of the second bone of the Fore finger. L 8, a *sinus* betwixt the two small heads of the first bone. M 8, a small head betwixt the two *sinus* of the 2. bone. N 9, the second bone of the Forefinger and his 2 heads. O 9, the third bone of the Forefinger containing 3 *sinus*. *Fig.* 10. A 10, The inside of the nayle hollow. B 10, his soft roote which the skin is wont to couer. C 10, the outside of the nayle gibbous. *Fig.* 11. A 11, the lower side of the Seedbone that is placed before the first ioynt of the great Toe. B 11, the vpper part of the same which is next vnto the ioynt. C 11. the vpper of another Seed-bone. D 11, the lower part. *a a* 11, the Seed-bones at the ioynt of the thumbe. *b b* 11, the seede-bones at the ioynt of the Forefinger. *c c* 11. Seede-bones placed at the little finger.

The fift bone of the wreſt on the outſide toward the thumbe, receiueth into his vpper ſinus the poſterior head of the firſt bone on the inſide, it receyueth into another Sinus the head of the ſixt Bone. It hath alſo a lower Sinus [tab.22.fig.3,6 c] which is long [fig. 6 a b] grauen ſomewhat deepe on the inſide and the outſide, [figu.6 c d] wherein it receyueth the head of the firſt bone of the thumbe, as alſo a part of the fifte bone of the Afterwreſt. [fig.3,4,6 e] It produceth alſo on his inſide a proceſſe [figu.1,3,6 O] to make waie for the Tendons of the Muſcles that bend the fingers, and ſo with the fourth bone maketh that paſſage hollow.

The ſixt Bone receiueth into his ſinus on the backſide the firſt bone, and his outwarde head entreth into the ſinus of the fift, his inner head alſo is ioyned with a plaine *ſuperficies* to the ſeauenth bone. This bone alſo receyueth the firſt bone of the Afterwreſt which ſupporteth the roote of the fore-finger, [figu.3,4,6 n] but the ſecond more obſcurely. [fi. 3,4,6 *f*.]

The ſeauenth, which is the greateſt of the ſecond ranke (as the ſixt is the leaſt) is eaſily luxed becauſe of his laxe connexion. It hath a round head which entreth into the ſinus which is common to the firſt and ſecond bone. It is alſo looſely articulated on the inſide to the ſixt bone, on the outſide with a depreſſed head to the eight bone, whereto it is likewiſe ioyned by the interpoſition of a griſtly Ligament. Finally, it is faſtned to the ſecond bone of the After wreſt.

The eight bone which like a wedge is placed between the third and the ſeuenth bones is ioyned at the left ſide with a depreſſed head to the third bone. On the right ſide with a depreſſed Sinus to the ſeuenth: before, his ſuperficies is broad, [Fig.3,4,6 K] whereby it is ioyned to the third bone of the After-wreſt and receiueth in a certaine Sinus [Fig.3,4, 6 L] the Heade of the fourth bone of the After-wreſt. It alſo produceth in the inſide of the wreſt a proceſſe which inclineth from the outſide inwarde, exſculped or grauen like the letter C. to make the hand hollow to containe the tendons of the muſcles that bend the Fingers. Out of the toppe of this proceſſe groweth the tranſuerſe Ligament of the wreſt, and to it is faſtned a ſeed-bone. [Fig.1 & 2 N] And thus much of the wreſt.

The next part of the Hand is called in Greeke μεταβράχιον, in Latine *Poſtbrachiale*, by ſome *Ima palma*, we will call it the After-wreſt. It is that part of the hande which is betwixt the wreſt and the rootes of the Fingers, and conſiſteth of foure bones, of fiue ſay ſome Anatomiſts, who reckon the firſt bone of the thumb with the Afterwreſt, becauſe we do not meete with it bare as the bones of the reſt of the Fingers are, but it lyes deeper as the other bones of the Afterwreſt. [ta.21.fig.1 & 2] The afterwreſt.

Theſe bones of the After-wreſt being placed betwixt the wreſt and the bones of the Fingers, [char.I.II.III.IV] are ioyned to the wreſt by *Coarticulation*; or rather by *doubtfull articulation* as they are ioyned to the bones of the Fingers by *dearticulation*; for al the bones of the After wreſt where they regard the Fingers do end into a rounde head, that ſo they might enter into the ſhallow or ſuperficiary cauities of the ſubſequent ioynts. Among themſelues they are ioyned onely by contaction of their extremities towardes the bones of the wreſt, where they are faſtned with griſtly Ligaments. [Fig.2 *r*] The bones of the afterwreſt

Theſe bones of the After wreſt are longer then the bones of the fingers, and the firſt of them which ſtandeth before the fore-finger is the longeſt and thickeſt of them, all the reſt are by degrees ſhorter and thinner; beſide they are all ſomewhat broader on the outſide then they are on the inſide.

Toward their extremities they growe thicke and haue Appendices growing to them aboue and below, [figu. 2 *r* ϙ] out of which Appendices yſſue Ligaments whereby theſe bones are ioyned together though that coniunction be ſomewhat diſſolute or looſe: for the vpper are faſtned to the bones of the wreſt, but the Appendices themſelues are tyed together by the interpoſition of a griſtlye Ligament. The lower appendices which are the greater are faſtned to the bones by coalition, for their head is round and long, forward and backward, lengthned out ſomewhat to the ſides, and cruſted ouer with a griſtle, and theſe heads do inſinuate themſelues into the Sinus of the firſt bones of the fingers.

Theſe bones are after a ſort round yet haue they as it were three ſides, two inward ſides ending into a line the better to giue way to the muſcles called *Interoſſei* or the *bone-bound* Muſcles, [fig. 1] and one externall which maketh the hand plaine. [fig.2]

There is alſo betwixt theſe Bones an intermediate diſtance, [figu. 1, 2 R] in which diſtance the *bone-bound* muſcles are placed, that is to ſay two in euery diſtance. And becauſe the The diſtance betwixt them

the palme of the Hand ſhould not ſwell too great by the bellies of theſe muſcles and ſo be made leſſe fit for comprehenſion, as alſo that the place might be ſufficient to containe them, theſe bones on the inſide which is next vnto the palme are curued & their outſide is gibbous: they are alſo cornered and haue ſwelling lines in them made for the inſertion of the muſcles in that place.

Their proceſſes. The firſt bone alſo where it is articulated with the wreſt hath a proceſſe [ta,22.fig.1, aboue char.6,and 7,]whereinto the ſecond muſcle that bendeth the wreſt is inſerted. In like manner the fourth bone ſwelleth on the outſide [figu,1,aboue *]into which ſwelling the third muſcle of the wreſt is inſerted. Note alſo that the palme of the hand is eſpecially made hollow by the firſt bone of the thumb (which ſome make the firſt of the After-wreſt) and by the fourth of the After-wreſt, for the other three doe helpe that cauity but little.

Vſe. Finally, the bones of the Afterwreſt are fiſtulated or hollow to contayne marrow. Their vſe is to eſtabliſh and ſtrengthen the Palme, that it might comprehend or containe whatſoeuer it is applyed vnto with more ſtedfaſtnes. And thus much of the VVreſt and Afterwreſt.

CHAP. XXXI *Of the Bones of the Fingers.*

THE Fingers which make the third part of the Hand are conſtrued or compounded of fifteene bones: for we ſay, ſayth *Bauhine*, that the thumbe alſo hath three bones. And becauſe they ſtand as it were in rank, therefore the Grecians haue called their order φαλάγγας, as it were the Files of a battell diſpoſed in order.

The row of the fingers,

The particular bones doe want proper names, and therefore are expreſſed by the names of the fingers to which they appertaine, as the firſt bone of the thumbe or the fore finger; the ſecond and the third and ſo in the reſt. Their number was with wonderfull wiſedome ordayned as was fitteſt for the facility and variety of motion, for if they had beene more they could not haue beene perfectly and ſtrongly extended: againe, if they had beene fewer the fingers could not haue beene moued into ſo many formes. *Galen* in his firſt and ſecond bookes *de vſu partium*, hath ſo elegantly diſcourſed of the counſell and wiſedome of Nature in this poynt that it will not onely delight any man that ſhall reade it, but alſo tranſport him as he himſelfe ſeemeth to haue beene tranſported into an admiration of the wonderfull wiſedome of the Creator.

Their forme The forme of theſe bones on the outſide (excepting the laſt) is gibbous and crooked, on the inſide it is plaine and ſomewhat hollowed or ſadled, partly becauſe we apprehend with the inſide of the hand, partly becauſe more tendons run into the inſide then into the outſide. Furthermore on their inſide ther are certain lines rũning on both ſides the bones throughout their length, from which lines certaine Ligaments are produced, which like rings doe encompaſſe the Tendons and hold them ſtedfaſtly in their places. Theſe bones although they be hard and faſt or denſe that the hand might vſe them in manifould imployments without danger or annoyance, yet they haue a cauity or hollowneſſe within them, which contayneth marrow.

Magnitude, Their magnitude is diuers, for the firſt bone of each finger is larger in all the dimenſions, that is, thicker, longer and broader then the ſecond, [ta,22,fig,1,2& 2,]in like manner the ſecond is greater thẽ the third; for Nature prouided that the thicker finger ſhold haue the thicker bones, and the longer finger the longer bones.. Notwithſtanding albeit their magnitude is not the ſame, yet they appeare all equall, & all the fingers are broght together into one right line when we would comprehend any round body. Moreouer they are in the beginning broader, and ſo grow narrower by degrees. At the ioynts all the bones are ſomewhat thicke, that the *baſis* being the larger the conſtruction might bee more ſubſtantiall: in their length they are not all of a thickneſſe leaſt their quantity or waight ſhould haue beene offenſiue. The ſwelling protuberations of the bones are called κόνδυλοι *Knots*, but in Engliſh Knuckles.

The bones of the firſt and ſecond ioynt haue Appendices aboue and below made for the originall and inſertion of muſcles: the bones of the third ioynt haue Appendices onely aboue; for the very end or head of the finger being not articulated againe but onely ioyned with fleſh or a nayle, needed no Appendix at all: they are alſo cruſted ouer with griſtles that the ioynt might be at all times glib and eaſie to moue.

The

The first bone of the thumb [tab.22.fig.1 & 2 ^] aboue, hath a long sinus, but before & behinde it buncheth out, that it might ioyne with the furrow or guttur of the fift bone of the wrest. It is manifestly mooued directly outward and inward toward the palm; sideward toward the forefinger, from which also it is remoued by reason of the length of the guttur, and beside it is turned circularly. But if the head of the bone of the wrest bee produced more backward then is the bone of the thumbe easily and directly bent backward, so haue I seene a man able to lay the Naile of his thumbe vpon his wrest. Some also will in like manner turne all their fingers vppon the backe of their hands. Aboue, this first bone of the thumbe hath a head but not perfectly round, which entreth into the sinus of the second bone. The first bone of the thumb.

The second Bone of the Thumbe where it regardeth the third is diuided by the Mediation of a long sinus [fig.8. L] into two long heads, [fig.8 ° ^] protuberating before on either side. The second.

The third bone hath two Sinus [fig.8, ^] distinguished by a long knor, [^] whereinto the heads of the second bone are receyued: againe the knub of the third bone entreth into the Sinus of the second so the second is receiued of the third, and the second receyueth the third, making thereby a *Ginglymes*, wherein the two Bones are so straightned, that onely the third bone can be bended or extended. The third.

After the same manner are the articulations made of the rest of the fingers, for they haue two heads and two bosomes. But the first ioynts of the foure fingers haue but one head and one bosome, because the bones of the After-wrest haue each but one Heade, which looketh especially into the inside of the Hande, and hath more abundance of gristly substance about it. The Sinus in the first bone of the foure fingers is orbicular, and aboue that head the first bone is bent, extended and moued to the sides. The third bone also it selfe swelleth into a gristly top and rough head [fig.9 O] whereinto is inserred the Tendon that bendeth it. Moreouer, all the inside is rough and vnequall, and at the end it is not knotted as the first and second bones are, but lyeth plaine to giue waie vnto the Nayles. The Bones of the Fingers.

CHAP. XXXIII. *Of the Seede-bones.*

THE last thing to bee considered in the Hande are the Seede-bones, called *sesamoides* [tab.22.fig.9] because they are like *Sesamum* seede. These Bones are placed in the ioyntes or knuckles of the fingers and of the toes: for the most part they grow vnto the Tendons and lurke vnder them; and therefore he that would make demonstration of them must seeke for them in the dissection of the Tendons of the Muscles which are seated about these bones. Moreouer, they are so entangled with ligaments, that if you desire to cleanse the bones, you shal take them away with the Ligaments vnlesse your care be the greater. They are crusted ouer with gristles, and touch the slippery side of the other bone. Solid they are, round, a litle depressed, sometimes gristly, sometimes bony, within fungous and full of pores, wherein they containe a iuyce which serueth them instead of marrow. How to finde the seed Bones.

These Seede-bones are commonly in each hand twelue, one standeth before the middest of the third ioynt, two at the second ioynt of the thumbe, [fig.1 & 2. S] two lesser which are gristly in the first knuckles of the foure fingers [Fig.1 ^] which leane vppon tendons, and are bent on either hand at the sides of the ioynt with the double tendon. In the rest of the ioynts of the foure fingers, that is in the second and the third at each ioynt there is one bone which is placed before the middest of one single tendon, and these are much lesser, [Fig.1, V] and as it were gristly, but yet larger in the hands then in the feet: in old men they grow big and almost plaine, in children they are but gristly & scarse conspicuous in the Tendons. Their number is not certaine as is the number of other bones, partly because they are so small that they are lost in dissections, partly saith *Archangelus*, because for want of seede Nature omitteth some things which are lesse necessary in the frame of the body. Their number

There is one little bone amongst these Seede-bones which may be numbred twice [fig 12 ^] because it is found in the hand neere the connection of that bone of the After-wrest which sustaineth the little Finger with the eighs bone of the wrest, for it filleth vp a place there on each side.

The vse of these Seed-bones is foure-fold: the first, that in certaine motions by their hard-

hardneſſe they might be better able to receiue and ſuſtaine the violence of the bone moued; for the Tendon is defended with ſuch a ſmall ſeed-bone to keepe it from ſhouldring vpon it ſelfe; for, in the extention of the fingers they inſinuate themſelues ſomwhat into the ſpace of the ioynt, and returne or holde the Tendon leaſt in the motion it ſhoulde fall from the ioynt as it ſwels.

The ſecond vſe is to hinder the bone, at which it is ſet, from luxing eaſily out of his ioynt, & ſo they are a defence to the ioynts, like as in the great ioynt of the knee the whirl-bone is as it were a ſhield or muniment to keepe the bones from luxation.

Their third vſe is to fill vp the diſtances which remained empty betwixt the bones of the fingers, and ſo againe they adde ſtrength vnto the ioynt.

Fourthly, to make the action of the hand which is apprehenſion more firme and conſtant. And this ſhall be ſufficient to haue ſaide concerning the bones of the whole hand, Onely we will adde.

That on the outſide of the ſingers there are nayles ſet [Tab.22.fig.12] to make their apprehenſions more diſtinct and ſtrong, and theſe nayles are neyther longer nor ſhorter then the ends of the fingers are, and therefore when they grow longer wee pare them off; otherwiſe they would hinder apprehenſion. And thus much of the bones of the hand. Now we proceed vnto the Foote.

CHAP. XXXIII. *Of the bone of the Thigh.*

THE Ancients called al that the foot which is betwixt the top of the Thigh and the top of the great toe. The bones of the Foote are 42, and belong ſome of them to the Thigh, ſome of them to the Legge, and ſome to the Foote commonly ſo called.

The Thigh is called by the Grecians μηρός, by the Latines *Femur* a *ferendo*, becauſe the creature is borne or ſuſtained eſpecially by theſe parts. It is alſo called *Femen* although ſaith *Varro* in his fourth booke, *Femina* are properly the inner parts of the *Coxæ*, and *Femora* the outward. The bone of the thigh is but one as is the bone of the arme. [Tab.23,fig.1,2,3.] In a man and an Ape it is the longeſt bone of the body, in other creatures wherein a great part of it lyeth hid, it is ſhorter then the Legge as it is in Birdes. The poſition of it is obliquely inward to the knee from the Hip-bone. The figure of it is long, round and ſtraight, but not exquiſitely becauſe it deſcendeth obliquely inward at the knee to make the ſtation or ſtanding, the walking and the running more firme and ſtrong, which alſo *Galen* euidently declareth in the 9 chap. of his booke *de vſu partium*, for thoſe men whoſe Thighes are more ſtreight and direct then it behooued, are called *Vari* and become lame in their knees. And it behooueth much that wee ſhoulde marke this poſture of the Thigh bone (being thereto councelled alſo by *Hippocrates*) leaſt if it be broken and be to be reſtored againe, he that mends the breach ſhould turne it the wrong way.

The figure of it.

On the foreſide it is gibbous, and that is profitable not onely for Seſion and ſitting, but for many other labours or operations which are performed when we ſit, as if a man would write vpon his knee, hold a Viall or any other thing betwixt his legs, or lay one leg ouer another. In the ſides it is round and ſmooth on both hands, on the backeſide doked or hollow aboue, it endeth into a head, a necke and two proceſſes, below it determines into a head which hath two productions and boſomes.

The vpper Head.

The vpper head [tab.23,fig.1,2,^ fig.3,ˣ ʸ the vpper] is wholy made of an orbicular Appendix which it hath, and is thicke and the largeſt head in the whole body. In ſo much as *Hippocrates*, in his booke *de fracturis*, cals it by an excellency ἄρθρον, *Articulum* the *Ioynt*. This head is round and long, the better to enter into the *cup* of the hip bone which is not onely deep of it ſelfe but indeed deeper by a large griſtle that compaſſeth the verges thereof.

And the reaſon why this cup was ſo deepe and the head ſo long, was that the articulation ſhould bee exceeding ſtrong becauſe of the enorme and huge waight which the thigh was to ſuſtaine. It is therefore articulated by *Enarticulation* which is a kinde of *Dearticulation*, and beſide to ſtrengthen it the more, and to faſten the two bones together, there ariſeth out of the cup of the hip an exceeding ſtrong and round ligament which is implanted into his *Sinus*, [Tab.23,fig.2,*] ſeated vnder the top of the head which is narrow and deepe. The head alſo is ſmooth and cruſted ouer with a griſtle that ſo the thigh might

might more easily and with greater expedition be bent, extended, mooued to the sides and circumflected or turned about.

Vnder the head is the necke of the thigh called αὐχὴν *Cerui*x. Ta.23,fig.1,2,3,[o] It is long and reaching vpward reclined also obliquely inward, least the thighes motion should haue beene hindered. Out of the necke where the bone groweth broader vnder [p] doe arise two knots which they call processes, or *Trochanters*, or *Rotatores*: and these Trochanters haue Appendices [Tab.23,fig.3,the middle x] which in children new borne (as also the head it selfe) may easily be separated, but in growne bodies they are so vnited with the prominent parts [fig.2, ϙ with ᵛ fig.1,ª with ᵇ] that there remaineth scarce any signe or footstep of an Appendix. The necke.

The vpper of these [fig.2,ϙ ᵛ] is the greater, and of all the processes in the body which are not ioyned to another bone simply the greatest: it bendeth vpward and outward. The lower [fig.1,2,ª] is farre lesser and looketh backward and inward. And both these are called *Rotatores*, eyther because they were made to turne the Thigh, or rather because the muscles which accomplish the motions of the Thigh are inserted into them. The first is called the great Trochanter and γλουτὸς, eyther because it is something like the Buttock, or because the muscles of the buttocke are inserted into it. The other is called the lesser Trochanter. These two processes are ioyned together by a line which buncheth out behind and runneth from without inward and so the bone of the Thigh becommeth round.

The vse of these Trochanters is like a little hill to admit the insertion of some muscles and to others to afford place of originall, for into the inner Trochanter is infixed the tendon of the first and second muscles which bend the Thigh: close vnto this there runneth a rough line [fig.2,ᶜ] obliquely downward and backward which seemeth to be parted into two and to reach vnto both the heads, but is more euidently terminated at the vtter head and into this line is the eight muscle of the Thigh implanted adhering verye closely thereto, for by the helpe of that muscle especially we stand vpright. The vse of the *Trochanters*

At the vtter processe there is a *Sinus*, certaine impressions, and a line to be obserued. The Sinus [fig.2,ᵈ] reguardeth the head of the Thigh, and into it are the ninth and tenth muscles of the thigh inserred. The impressions are foure at the vtter gibbous part which receiue the Tendons of foure muscles. The first in the backward and lower side; [fi.2,ϙ] it is a large impression which receiueth the tendon of the first muscle of the thigh, [fig.1,τ] in the foreside which is also the rougher and receiueth the tendon of the seconde muscle; the third in the vpper and vtter part [fig.1,β below τ and υ] which is gibbous and made to receiue the tendon of the third muscle: the fourth [figu.1,and 2,ᵛ] is in the very top of the processe and narrower then the rest, and admitteth the tendon of the fourth muscle. But from the roote of this processe on the anterior and the exterior side ariseth the seauenth muscle of the head. The line wee spake of is rough and runneth from the first impression downeward and somewhat obliquely through the backside of the thigh, and into it is the first muscle of the thigh implanted. The sinus of the thigh. The line.

Now below the middle Region the Thigh as it descendeth [fig.2.from ᵈ to ᵉ] it becommeth thicker, is dilated and depressed, [fi.2.ᵉ] in which depression a veine, an artery and a nerue do securely run, and at length it determineth into an ample and broad head, which latitude is made by a large Appendix. [ta.23.fig.3.ˣ ᵞ the lower] Out of the backeside of this head are produced two processes as it were two other heades, [fig.1 & 2 ᶻ ᶻ] betwixt which there is a large space left about an inch broade, [figu.2.l] which receiueth a protuberation swelling out of the head of the Leg-bone.

These two heades are on the outside rough, but their superficies is smooth, because of a gristle which compasseth them to make the motion at the knee more expedite or easie. These heads doe bend more backward, and in the sides are scarce depressed at all, because of the articulation of the Thigh with the Legge-bone. [ioyne ta.23.fig.1 and 2.ᶻ ᶻ, with ta.24.fig.7.ᵒ ᵞ] which is made by *Ginglymoi*, for these two heades of the Thigh doe sit in two bosomes or cauities of the Legge-bone, and the protuberation of the Legge bone which swelleth vp betwixt his sinus [ta.24.fig.7.l betwixt ᵒ and ᵞ] is receiued by the posterior sinus of the Thigh-bone. [ta.23.fig.2.l] Moreouer the Thigh is fastned with the Leg below, as it was aboue with the Hip-bone by a strong ligament produced from the protuberation of the Leg-bone. The lower heads of the thigh.

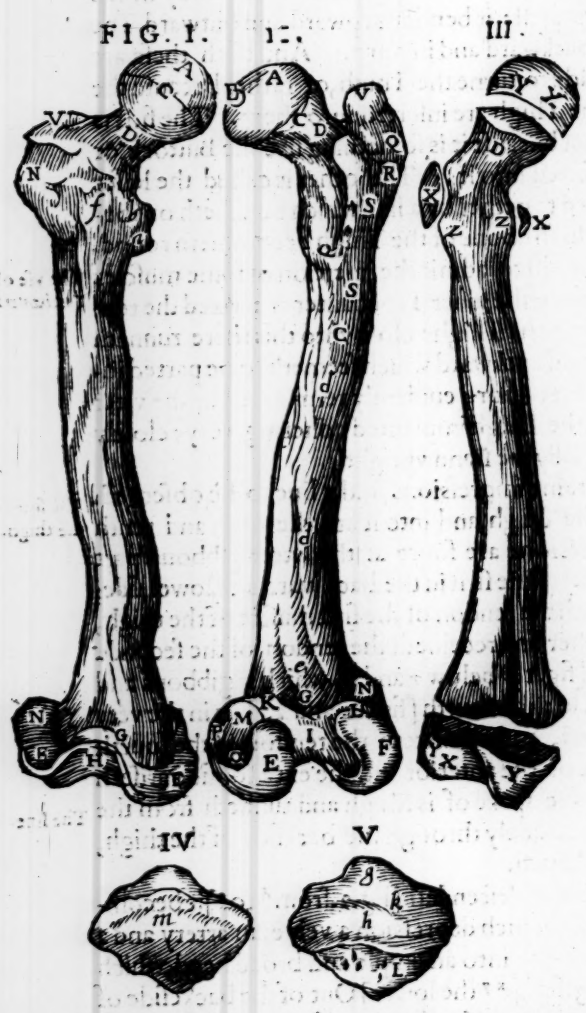
Of these heads, one is internall which is the thicker; another externall which is broader and more depressed, least both of them should bee equally articulated to the Legge

Table 23. Figure 1. and 2 shewe the fore and hinder part of the thigh-bone.

Figure 3 sheweth the thigh, whose Appendices wee haue remooued out of their place, and disioyned with a little distance.

Figure 4 and 5. The fourth sheweth the anterior and rough side of the Pattel-bone; the fift his posterior part crusted ouer.

TABVLA XXIII.



A 1,2. The head of the thigh going into the Cup of the Hip-bone.

B 2, A sinus into the head of the Thigh, into which is inserted a round Ligament.

C 1,2, The coniunction of the Appendix of the thigh with the bone it selfe.

D 1 2,3, the necke of the thigh.

E,F, the two lower heads of the thigh.

G 1,2, the coniunction of the lower appendix,

H 1, I 2, A sinus betwixt the two heades of the Thigh.

K 2, A part of the lower heade of the thigh from whence the first muscle of the foote doth proceede.

L 2, Another part from whence the seconde and third Muscles arise.

M 2, Another part to which the Tendon of the fift Muscle of the thigh is infixed.

N 1,2 A sinus of the outward side of the head for the fourth muscle of the legge.

O 2, A sinus of the inside through which the tendons do passe.

P 2, a protuberation at which the saide tendons are reflected.

Q 2, the vtter processe of the thigh, and betwixt Q and D is the sinus.

R 1,2, the vnion of the processe with the thigh.

SS 2, a rough line from the impression of the externall processe.

T 1, the anterior impression of the internall processes.

s, betwixt T and V another impression higher then the former.

V 1,2, the fourth impression in the toppe of the processe.

X 3. Foure X, shew the foure appendices of the thigh.

Y 3, Three Y shew the three heades of the thigh.

ZZ 3, Two processes of the thigh.

a 1, the anterior processe of the thigh

b 1, the coniunction of the processe with the thigh.

cc 2, a line descending obliquely from the inner processe.

dd 2, a line running thorough the length of the thigh.

e 2, The largeness of the thigh in this part.

f 1 a roughnesse from which the eight muscle yssueth. *g,b* 5, a knub of the Whirle-bone going into the sinus marked with I which is betwixt the heads of the thigh. *i* 5, a sinus fitted for the inner head of the thigh. *k* 5, a sinus agreeing with the externall head of the thigh. *l* 5. The lower asperity or roughnesse. *m* 4, The foreside of the pattell or whirle-bone rough or vnequall.

and so the oblique motion made by the muscle of the Ham called *Popliteus* bee interrupted; for this muscle yssueth from the externall heade where it is exasperated with small cauities, and these heads as is saide doe enter into the sinus of the Legge-bone. From these processes as it were, the three first muscles that moue the foot take their Original; as also the tendon of the fift muscle of the thigh is infixed into the side of the inner head, [M] where the compression is marked. [figu. 2 R] Their sides are full of blinde holes, out which do yssue the Ligaments which hold together the ioynt of the knee.

They haue also foure sinus or cauities, two in the middle of the head, and one in the sides on either hand. The first of these which is the forward [tab. 23. fig. 1.ª] is crusted ouer with a gristle and receyueth the protuberation of the Pan: [figu. 5. g^{h}] the second and the backward [fig. 2 I] is deepe, rough and vnequall, and receyueth the protuberation of the

Legge-

leg-bone: [ta.24,fig.7,I] the third is at the outside of the head, [fig.12,N] through which the tendon of the fourth muscle of the legge reflected in this place is safely transported: the fourth Sinus is at the inner head [fig.2,O] wherein the tendons of the first, seconde, third and fift muscles of the legge are safely conuayed.

On the foreside at the roote of the necke the thighbone is large and rough, [fig.1,f] so framed for the originall of the eight muscle of the legge: on the backside it buncheth out with a rough and vnequall line [fig.2,dd] into which the fift muscle of the thigh is infixed.

Finally, on the outside throughout the length of the bone there is a large *sinus* or cauity made not so much for lightnes as to containe great store of marrow for nourishment and therfore the vpper part of the bone, but especially the lower, is thrilled through with many small perforations whereinto the veynes are admitted which bring blood vnto that place. The vse of the thigh is for progression; now some creatures do moue right vp, some bending downeward, and this variety is made by the different insertion of that round and strong ligament which ysslueth out of the Thigh and is inserted into the cup, for if the insertion be made, saith *Archangelus*, toward the vpper part of the cuppe, then the creature walketh streight vp as a man doth, if it be inserted toward the laterall parte then his gate is prone or inclined to the earth, as an Oxe or an Horse. And thus much of the bone of the Thigh. The vse of the thigh.

CHAP.XXXIIII. *Of the two bones of the Legge.*

WEe call all that the Legge which is betwixt the knee and the in-step, and it hath two bones as the Cubit had, [Tab.24,figu. 1,and 2,] and surely if it had consisted of one thicke and great bone it would not haue beene so fit for motion, which would haue beene hindered by the grauity or weight thereof, as *Galen* excellently sheweth in the 13 chap. of his third booke *de vsu partium*. Of these bones the inner is called κνήμη, *Tibia*, carying the name of the whole, and so we call it the Leg-bone, [fig.3,4, the vtter is called περόνη *Fibula*, [fig.1,and 6,] wee call it the Brace bone or if you will the Shinne bone. The names of the bones of the legge.

The Legbone is called *Tibia*, haply because it is like a Fluite, it is called also *Canna maior*, for so also a Fluite in latine is called. If you will for difference sake we may call *Tibia* the Shanke, and *Fibula* the Shin bone, or if you had rather retaine the vertue of the latine names call *Tibia* the Leg-bone and *Fibula* the Brace bone. The leg-bone is the inner and the thicker, somwhat shorter then the Thigh to which it is ioyned, otherwise it is the longest of all the bones.

The figure of it is long and three square, thicke aboue and below and eeked with an Appendix. [Tab.24,fig.1,and 3, A B DD] It is also made vnequall with long cauities and lines and is articulated aboue with the Thigh, below with the *talus* or Coccal, or bone of the instep by *Ginglymos*. His figure.

The vpper part which they call the vpper head is broader then the lower, for the legge was made to beare the thigh, and this bredth is formed by an Appendix which is set like a cup vppon the head of the bone. [tab.24,fig.1,3, A B] This Appendix is thicke and before inclineth somthing more downward then it doth behind, [fi.1,3, B] it hath two long Sinus, [figu.2,and 7, F G] which are but shallow and crusted ouer with a slippery Gristle wherein to it receiueth the two heads of the Thigh, [ta.23, fig.2,E,F,] and so a *Gynglymos* is made. But because the proper cauity of these Sinus was not deep enough to receiue the length of the heads of the thigh an amends is made and the Sinus encreased in al cretures by a peculiar gristle [fig.8,] like a halfe moone, which is therefore called *Cartilago Lunata*, the *Crescent Gristle*; and this gristle is softened by ligaments. This gristle is mooueable and thicke in the circumference or Verge, [fig,8,N] & yet toward the Center it is alwayes attenuated [fig.8,OO] toward the Center I say, for it doth not reach so farre as to the Center but endeth on eyther hand into sharpe tops, [fi.8,PP] yet so that before these tops doe meete; for the right is ioyned to the left, but behind they are more distant to giue way to a thick ligament that passeth betwixt them. The gristle also is slippery, smooth, and soft, ful of an vnctious or oily humor to further the motion of the ioynt, and it supplyeth the office of a ligament. His vpper part. his gristle.

These two Sinus are separated by a rough and vnequall protuberation [fig.7,H I K] growing out of the middle superficies of the leg and shank-bone, which protuberation is

receiued by the sinus of the thigh [tab.23.fig.21] which is betwixt his two heads. Out of the rough and sinuated top [tab.24.fig.2,3,4,7 I] of this protuberation on the backe side yssueth [tab.24.fig.2 47 K] a strong Ligament which is infixed into the middle of the sinus of the thigh, [tab.23.fig.21] that the ioynt being thus on euery side defended, might the better be contained in his owne place. From the anterior part of the protuberation [tab.24.fig.1,7 n] which is rough and sinewated, are produced certaine Ligamentes which on the foreside of the protuberation do ioyne the gristles together which encrease the cauities of the shanke, [fig.8, lm] although also they grow together by the interposition of that orbicular or round Ligament which compasseth the knee.

His Head. Out of the Appendix at the vtter side of the legge ariseth a little head [tab.24.fig.4 R] which is crusted ouer with a gristle and entreth into the vpper sinus [fig.5. s] of the Appendix of the Brace or shin-bone, so the anterior part which is next to the appendix [tab.24.fig.1,3,7 nn] is rough and full of holes, whereinto the tendons of the Muscles that moue the legge are very strongly inserted.

From hence the Leg-bone is by degrees attenuated, diuersly also distinguished with lines and cauities, and imitateth the forme of a triangular; for it hath one corner like a long and sharp edge which is situate in the forepart; the seconde corner is in the Vtter part, the third in the inside; and betwixt these Angles the bone lies plain but lightly excauated, as well to make it more light, as also for the insertion and original of the Muscles. On the backside it is round.

His Lines. The anteriour part and the middle is produced or lengthened vnto an acute and long angle, [tab.24.fig.1,3,7 2] which angle is as sharpe as the edge of a knife, and therefore it is called *spina tibia*, the spine of the Legge by the best Anatomists.

The second line [tab.24.fig.1,2,3,4 o] which maketh the vtter angle of the backside is also sharpe, and is seated vnder the Brace: this line receiueth the Ligament which fasteneth the shin and the shank-bones together.

The third line [fig.1,2,3,4 q] which maketh the internall angle of the backeside is blunt and almost round. Wherefore these lines do make the three sides of the leg. The first side [fig.1,3 ζ] is sinuated but plain, and together with the side of the Brace [fig.1,5 x] it affoordeth a place vnto the anteriot muscles which descend vnto the foote. The second side [fig.1,3,5 w] is inner and gibbous which by some is called ἀντικνήμιον, by some κνήμη, in a contrary sense, because it hath no flesh at all, although the other sides especially behind be very fleshy. The third side [fig.2,4 θ] the posterior muscles of the Thigh do occupie, and in it aboue we meete with another rough line running obliquely downward [fig.2 π] [fig.4,x] made for the insertion of the muscle of the Ham.

His Sinus. On the outside aboue the lower heade there is also a long sinus which runneth backeward, [t.24.fig.4,10, r] which receyueth the interior part of the head of the brace-bone which is a little rough, [fig.5,6,11,7] and so the Brace and the Leg, or the shin and the shank are ioyned together; but where these bones are conioyned there commeth a strong Ligament betwixt them, which fasteneth them together both in the circumference, and wher they touch one another. So also behind it is depressed [fig.2,4 m] and sheweth as it were three sinus which conuey the three Tendons of the fift muscle of the foote, and the two benders of the toes, for these muscles run out vnto the foote.

The lower part of the leg. The lower part of the Legge or the lower heade is thicke, which for all the appendix that is added and the plentifull gristle wherewith it is crusted ouer and made broader is notwithstanding lesser then the vpper, whose Appendix together with the appendix of the Brace, do make in the surface a large sinus [fig.9, defgh] which receiueth the *Talus* [tab.25,fig.3,4,5,6] or the Coccall-bone: but in the appendix of the leg bone there is as it were a double sinus [figure.9,10 e f] distinguished by a swelling knot which buncheth lightly in the middest betwixt them. [fig.7,10 d]

It hath also a thicke processe yssuing from the inside, [tab.24.fi.1, Φ,2,3,9,10 i] which processe in that part that regardeth the sinus, [fig.9,8] is hollow, smooth and crusted ouer with a gristle whereby the cauity is enlarged, and by that means it receyueth the *Talus* more commodiously, for that being inserted into the Sinus it cannot be mooued out of his place. The other side of the processe which regardeth the other Legge is gibbous and without flesh. [fig.2,3,9,10 i] But in the opposite part the legge could not haue had another processe, because it was necessary that in it there should bee a long sinus, into which a part of the Brace-bone was to enter.

This

Table 24. sheweth the bones of the Legge and the Brace, together with the gristles about the knee.

Fig. 1 & 2. shewe the right Legge whole, both the fore-part and the back-part.

Fig. 3 & 4. shew the foreside and the backside of the Legge or Shank-bone.

Fig. 5 & 6. shew the foreside and the backside of the Brace or Shin-bone.

Fig. 7. sheweth the vpper part of the Shanke-bone to which the thigh is articulated.

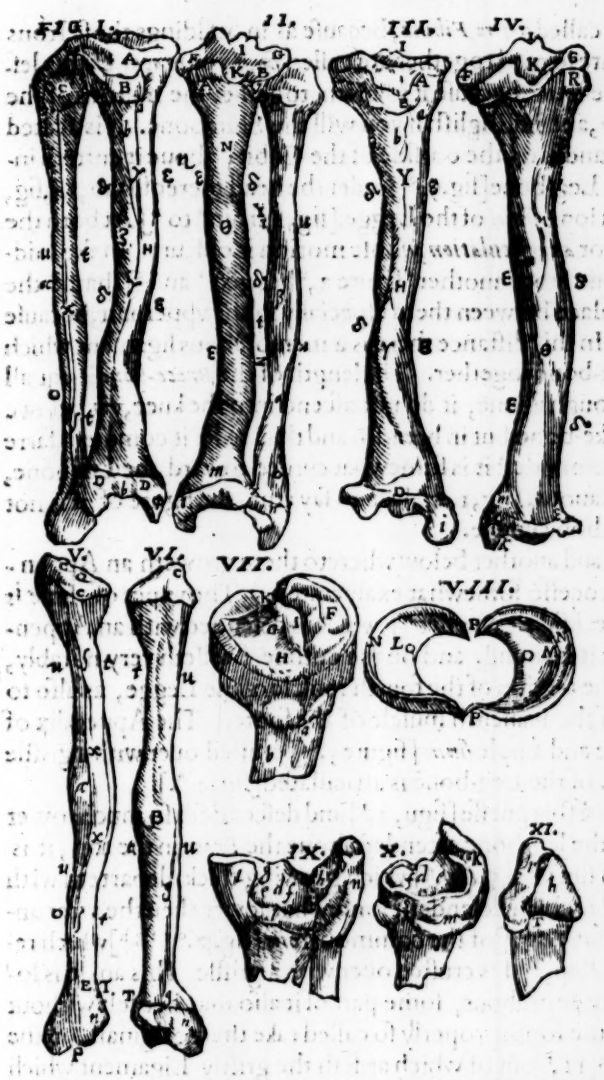
Fig. 8. two gristles increasing the cauity of the ioynt of the Leg-bone at the knee.

Fig. 9. the lower part of the whole Leg where on the foreside it receiueth the Talus or the Instep.

Fig. 10. the backpart of the lower end of the Leg-bone.

Figure 11. sheweth the inside of the lower end of the Brace or Shin-bone where it is articulated with the Talus or Instep.

TABVLA XXIIII.



AB 1, The vpper Appendix of the Legge or shanke-bone.

AB 2,3, The line where the Appendix ioyneth with the bone.

C 1, The vpper appendix of the Brace-bone.

C 5, the coniunction of this appendix with the bone.

DD 1, the lower appendix of the Leg-bone.

D 3, the coniunction of this appendix with the bone.

E 1 the lower appendix of the Brace or shin-bone

FG 2, 4 7, the bosomes of the bones of the Leg receiuing the heads of the thigh bone.

HIK 7, A protuberation which is betwixt these cauities. K L in the second, third and fourth figures doe shew the same.

LM 8, a gristle encreasing the outward cauity of the Leg-bone L, another increasing the inner cauity M.

N 8, the foreside gristles do in this place appeare thickest.

O 8, and here they appeare thinnest.

P 8, here they do determine into sharp points

Q 5, A shallowe *sinus* of the Brace bone in which the head of the leg-bone is articulated.

R 4, the head of the Legbone which is ioyned to the Brace.

S 4, 10, A *sinus* of the Legbone receiuing the lower end of the Brace bone.

T 5, 6, 11, the inside of the Brace where it is ioyned to the bone of the Leg.

V 2, the context of coniunction of the Brace with the Legbone aboue.

X 2, the same coniunction below.

Y 2, the distance betwixt the shanke and shin bones.

Z 1, 2, The oblique turning of the Brace inward which on the outside is somwhat indented.

a b 1, 3, the forepart of the Legbone wherinto the muscles which extend the Leg are inserted.

c 5, 6, the vpper processe of the Appendix of the Bracebone, whereinto is inserted the tendon of the fourth muscle of the Legge.

d e f g h 9, At this place the vpper part of the *talus* or instep is articulated: in the ninth & tenth figures *d e f* shew the vpper region, but *d* noteth the protuberation.

h 9, 11, the outside where it is fitted with the instep.

◆ the inner ankle or a processe of the inner appendix of the Legbone.

i 2, 3, 9, 10, the inner ankle.

k 4, 10, a *sinus* of the inner ankle from whence a gristly ligament is inserted into the instep

l 1 3, 9. an vnequall *sinus* in the lower appendix of the Legge bone, whence groweth a gristly ligament which is sent vnto the necke of the instep.

m 2, 4, 10, certaine *sinus* through which three tendons are led to the foot.

n 2, 5 6, 9, the outer ankle or the processe of the shin bone in the first figure noted with E. *o p* 1, 5, that part of the shin bone which is bare. *q q* 2, 6, in this situated place of the shin bone the tendons of the seauenth and eight muscles of the foot are reflected *r* 2, 6, 11, a *sinus* of the appendix of the shin bone from whence goeth a ligament into the instep. *ſſ* 1, 5, the first line of the shin bone. *tt* 2, 5, 6, the second line of the shinbone. *nn* 1, 2, 5, 6, the 3. line of the shin bone. *xx* 1, 5, the first side of the shin bone bunching a little out. *αα* 1, 5, the 2 side of the shin bone. *ββ* 2, 6, the 3 side of the shin bone. *γγ* 1, 3, the first line of the leg bone. *δδδδ* 1, 2 3, 4, the 2 line of the leg bone. *εε* 1, 2, 3, 4, the 3 line of the leg bone. *ζ* 1, 3, the first side of the legbone. *η* 1, 3 the 2. side of the leg bone. *θ*, 2, 4, the 3, side of the leg bone. *N* 2, *x*, 4, a rough line of the third side of the leg bone made for the muscle called *Popliteus*.

This processe is by degrees dilated and determineth into two browes, wherefore also the shinne-bone or the *fibula* departeth into a processe, that so the bone of the *Talus* might be contayned or kept in by both the processes, that it should not slippe out on this side nor on that side. And if at any time the luxation of the *Talus* doe happen, it is rather to the inner processe then to the vtter, because the proces of the *Brace-bone* is lengthned out somewhat longer then the other.

The Ankles

These processes are called *σφυρὰ malleoli* the Ankles, the processe of the Leg-bone is called the inner ankle, and the processe of the *Brace-bone* is called the vtter ankle.

The inner ankle.

The inner Ankle [figure 1,[r] fig,2,3,9,10,[i]] in the lower end of the backepart hath a rough *sinus* [fig,4,10,[k]] whereout yssueth a gristly ligament whereby the bone of the leg is fastned to the *Talus*, so likewise in the lower and foreside [figu,1,3,9,[l]] of the appendix there is a *sinus* rough, transuerse and long, from whence groweth a ligament which fastneth the necke of the *Talus* [ta.25,fig.3,[n]] to the leg-bone.

His vse.

Finally, this bone as also the *Brace* is notably hollowed within, and that cauity conteyneth they marrow, neither is it without other perforations. The vse of the Leg-bone sayth *Archangelus* is to make the progression more expedite and nimble. And thus much of the Leg or Shank-bone.

Of the Brace or Shin-bone.

The brace bone. His names.

The other bone of the Legge is called *περόνη Fibula*, because as in buildings those Irons whereby the beames and pannes are ioyned together are called *fibulæ* or *braces*, so this lesser bone may also be well called the *Brace*, because it ioyneth together the muscles of the Legge: it is also called *canna minor*, and in English if you will the Shin-bone. It is seated on the outside of the Leg as the wand is on the outside of the Cubit; aboue it entreth into a plaine and crusted *sinus* of the Leg-bone [fig.5,[q]] vnder the head thereof; [tab,24,fig,1,[c] vnder [A]] below it entreth into a long *sinus* of the Legge. [fig,1, from [a] to [p]] At both the ends it is articulated by *Arthrodia* or *adarticulation*, whose motion is obscure. In the middest the two bones doe stand off one from another [figure 2,[y] betwixt [y] and [x]] that so the muscles of the foote might finde place between them especially in the vpperpart, because there the Leg is bent into a *sinus*. In this distance there is a membranous ligament which fastneth the skinne and the shanke-bone together. The length of the *Brace-bone* is equall to the length of the other, for although aboue, it do not ascend into the knee, yet belowe it descendeth lower then the shanke-bone, but in breadth and thickneſse it commeth farre short. Moreouer a little vnder the middest it is somewhat curued toward the Legbone, and the outside is after a sort concauous, [fig,1,2,[z]] yea to say true, the figure of it is not much vnlike the figure of the Leg-bone it selfe.

His heads

It hath two heades, one aboue and another below whereto there groweth an Appendix which endeth into an acute processe somewhat exasperated. The vpper of these is

the vpper.

below the head of the shanke-bone, [figu,1,[c] vnder [A]] which is defended with an Appendix and crusted ouer with a gristle: it is round, and on the outside swelleth very notably, [figu,5,[b c]] the better to receiue the tendon of the fourth muscle of the Legge, as also to giue an originall vnto the head of the seauenth muscle of the foote. The Appendix of this head hath on the inside a large and ample *sinus* [figure 5.[q]] crusted ouer with a gristle whereto the head of the Appendix of the Leg-bone is articulated [fig,4,[z].]

the lower.

The lower head tendeth into a sharpneſse [figu, 1,[z]] and descendeth so much lower then the Leg-bone, as the head of the leg-bone ascended aboue the *Brace* in the top; it is also furnished with one appendix [fig.1 [z] 2,5,6,9,[n]] which growing thick departeth with a processe called the outward ankle, which descendeth somewhat lower then the vtter ankle and maketh the externall side [fig.9.11.[h]] of the common *sinus* [fig.7.[d e f g h]] which receiueth the *Talus* or bone of the instep, and is crusted ouer with a gristle. This ankle is lower then the inner, and on the outside gibbous, some part of it also may bee felt without flesh, and from it some muscles of the foote properly so called take their originall, on the inside it hath a rough *sinus* [fig.2,6,11,[r]] out of which ariseth the gristly Ligament which fastneth the *Brace* or shin-bone to the instep. Aboue the Ankle there is a *sinus* [fig.2,6,[q]] couered with a transuerse Ligament, where vnder the tendons of the sixt and seauenth

the lines,

muscles of the foote are safely conuayed.

Betwixt these two heads the body of the *Brace* or shin-bone is vnequall, because of cauities and lines therein made for the insertion of muscles: so that about the middle it

seemeth

seemeth to be triangular; for before there appeareth an acute and swelling line, [fig.1.2.ff] behind it is depressed and hath on either hand a strutting line, [fig.1,2.5.6.ggg] and these lines make the three sides of the *Brace-bone*. [fig.1,5,7,2,6.h] In like manner at the lower end aboue the appendix [fig.5.6.11.i] there buncheth out an asperity, at which place by the interposition of a ligament it is fastned to the shanke or leg-bone.

The vse of the *Brace-bone* is threefold: the first to ioyne the Leg and the Instep, whereby the foote is bent and extended: secondly to defend the vessels and muscles of the Leg from outward iniuries, for the *Brace-bone* couereth for the most part the course of them all. Thirdly, to sustaine, strengthen and secure the Legge by fastening it to the outward head of the Thigh-bone. Moreouer, as the wand helpeth to moue the Hand, so the *Brace-bone* helpeth to moue the Foot in compasse, saith *Archangelus*. The vse of it.

CHAP. XXXV. *Of the whirle-bone of the Knee.*

BEfore we part from the Leg, you must remember that there is a bone placed before the ioynt of the Knee [tab.23.figu.4.and 5.] which the Grecians call ἐπιγονατὶς & ἐπιγονὶς, because it lieth vpon the knee; others call it μύλη the Milstone, because it is very like it. *Celsus* calleth it *patella* or the *Sawcer*. It is also very commonly called *Rotula*, we will call it the Whirle-bone. The names of the whirle bone.

It is a bone common to the Thigh & the Leg although it be separated from them both, for it is placed before their articulation. In each knee there is one, somewhat round and broad and ending into a sharpnesse where it resteth vpon the Leg. The magnitude of it is moderate, the latitude scarce two fingers broade, the longitude is somewhat thereabouts, the thicknesse is vnequall, for in the extremities it is thinne and growes thicker by degrees, so that in the middest it buncheth out like a compassed buckler, or if yo ɔ will, like an embowed Looking glasse such as they vsed in ancient times. The vpper part therof groweth to the thicke Tendons of the seauenth, eight and ninth muscles of the Thigh, which by the knee doe runne vnto the Leg: by these Tendons it is established, for they serue it in steade of a Ligament to fasten it both to the Thigh and to the Leg: moreouer on the outside it is coueredby them; on the inside it is crusted ouer with a smooth and slippery gristle, at lest the greatest part of it; especially where it regardeth the Thigh, and this gristle maketh the motion more glib, for it will easily moue vnder a mans finger. *Columbus* cannot taste this conceit, but sayeth that it is fastned both to the Thigh and to the Leg by Ligaments of his owne, which sayeth hee doe grow from the Appendices of the Thigh and the Legge, so also sayth *Archangelus*, yet he doth not deny but it is established by the Tendons of the muscles before spoken of. But *Bauhine* leaneth more to the first opinion of *Vesalius*, that it hath no other Ligaments but the Tendons. If these Tendons to which it groweth be cunningly taken away it will appeare both before and in the sides [ta.24.fig.4.] rough and full of blind holes, but behinde it hath a moderate protuberation [fig.5.g h] and shallow bosoms on either side [fig.5.i k] crusted ouer with a gristle of which the vtter is the larger and the broader. How it is fastned.

This protuberation wee spake of, is receiued by the *sinus* which is betwixt the heads of the Thigh, [f.1." betwixt " "] like as the bosome of this whirlebone receiueth the heads of the Thigh; wherefore the Thigh receiueth the whirle & the whirle the Thigh, and so are ioyned by *Ginglymos*, but the whirle and the Leg-bone are ioyned by *adarticulation*; wherefore it is moouable least it should make the motion of that ioynt difficile or hard. Moreouer the inner and lower part [fig.5.l] where it groweth into a processe and regardeth the vpper part of the Legge-bone, is rough and perforated that it might growe the faster to the Tendons of the foresaid muscles. His articulation,

The substance of the whirle is at the first gristly and so remayneth for certain months. Afterward it groweth as hard as a hard Appendix, and at length bony, hard & solid, such as it appeareth in growne bodies, so sayth *Eustachius* in his obseruations, and with him *Bauhine* consenteth; *Columbus* thinketh it groweth not beyonde the height of an hard Appendix.

The vse of it is to couer and to firme the laxe and dissolute composition of the ioynt of the Thigh and the Leg, least in progression and walking the Thigh should luxe outward, as also that when we goe downe a hill it might support the ioynt. Moreouer, by the help of the whirle when the knee is gathered directly backward it is bent into a right angle.

Finally

Finally, it defendeth the Tendons of the foreſaid muſcles, leaſt in the bending of the knee when the Thigh bone preſſeth forward it ſhould beare to hard vppon them; and in a worde as the Seede-bones of which wee ſpake before, the hardneſſe of it receiueth the violence of the Thigh-bone, and breaketh it that it ſhoulde not compreſſe thoſe Tendons.

CHAP. XXXVI. *Of the Bones of the foote properly ſo called, and particularly of the Wreſt of the Foote.*

WE are now come vnto the third and laſt part of the Foote, which is properly called the Foote, and *Pes extremus* or *Pes paruus*. It hath 38. bones and three parts. The firſt part is called *Tarſus*, which we call the wreſt of the Foot, and hath ſeauen bones.

The ſecond is called *metatarſus* or *pedium*, the Afterwreſt of the Foote & hath fiue bones.

The third part is of the Toes, which haue foureteene bones, to which wee may adde twelue Seed-bones. Of theſe in order.

Of the ſeauen bones of the *Tarſus* or wreſt of the Foot: foure haue names, the other three are not ſo much beholding yet vnto Anatomiſts.

The firſt bone of the Tarſus. The firſt [tab. 25. fig. 1. and 2. T and the whole third, fourth fift, and ſixt figures] which the Greciancs cal ἀστράγαλος and ἄστριβος, the Latins *Os baliſtæ* and *Talus*. The Dye or paſtern bone lyeth vnder the Appendices of the ſhinne and ſhanke-bones as a firme and ſtable foundation, and yet it ſeemeth to lye onely vnder the ſhanke, and this bone is not onelye found in men but in all other creatures whoſe feete are deuided into Toes. In the vpper part thereof there is a ſmooth and round knub [fig. 3.4.6.^{ABCD}] cruſted ouer with a griſtle, which repreſenteth the forme of the nut of a Croſſe bow or the fourth part of a wheele. The ſurface alſo of the knot is as it were foure ſquare, limitted about the edges with foure ſides, and therefore by ſome is called *quatrio*: the firſt and ſecond of theſe [fig. 3. 5.6. from ^{A} to ^{B} and from ^{C} to ^{D}] goe through his length: the third is on the foreſide [from ^{A} to ^{C}] the fourth on the backſide. [from ^{C} to ^{D}] In the middle it hath a ſhallow cauity [fig. 3.^{EE}] with riſing ſides [figu. 3.^{FF}] like the ſides of the furrow of a pulley wherein the rope runneth, by which *ſinus* it is coupled by *Ginglymos* with the appendix of the ſhankbone. [tab. 24. fig. 9. 10.^{def}] The ſides of it are plaine and ſloping, cruſted ouer with a thinne griſtle to receiue the Ankles: the inſide [fig. 5.^{O}] is cruſted but a little way, and receiueth the inner Ankle of the Legge: the outſide is broader [fig. 6.^{N}] and more hollowed, deſcending lower the better to admit the outward ankle of the Brace-bone which alſo deſcendeth lower. [tab. 24. fig. 9. 11.^{b}] And thus the *Talus* is ioyned with the Leg and the Brace, which articulation ſerueth for the right motion of the foote, which that it might more eaſily perfourme and without attrition of the bones, it is on both hands cruſted ouer with a griſtle.

Furthermore, on the inſide it hath a rough *ſinus* [figu. 5. I] where into a griſtly Ligament is receiued which groweth from the inner ankle, and whereby the *Talus* is faſtned to the ſhanke. Againe, on the outſide fig. 6.^{S}] there is another *ſinus* which receiueth a Ligament produced from the outward ankle. Moreouer, on the backſide at the root of the protuberation where it is ioyned to the Leg and the heele [fig. 5. after ^{BD}] there is a roughnes, partly to receiue the ligaments which grow from the Leg, partly to reach other ligaments vnto the heele. There is alſo in the backepart [figure 5.6.^{LM}] a *ſinus* prepared for the tranſition of the tendons of muſcles which attaine to the ſole of the foote.

Yet further, this firſt bone is not onely ioyned with the ſhin and the ſhanke, but alſo with the *Boate-bone*, and therefore the forepart of the *Talus* is lengthned into a long neck, [figu. 3,4,5,6,^{N}] and the necke endeth into a round head [O] couered ouer with a ſlippery griſtle which is receiued by the large and round *ſinus* or boſom [fig. 11.^{S}] of the *bote-bone*, and by the meanes hereof the foote is moderately and with an obſcure motion mooued inward and outward, and ſomething alſo in compaſſe.

At the Heele alſo this *Die* or *paſterne-bone* is faſtned with a double ioynt, and therfore the lower part thereof hath on the backſide a large and deepe *ſinus* [fig. 4.^{Q}] couered ouer with a griſtle, into which the large and broad head [figu. 7.8.9.^{T}] of the heelebone is inſerted: before it hath a long and ſmooth protuberation [fig. 4.^{S}] which is receiued by a long boſome [figu. 7.8.9.^{S}] on the backſide of the heele. Betwixt theſe two ſpaces or in the

the middeſt of theſe ioynts there is a deepe and rough cauity [figu. 4, ᵛᵛ] whereto the ſinus of the heele [fig. 7, 8, 9, ᵃ] is oppoſite and anſwerable: the vſe of which cauity is to contain a mucous ſubſtance and fat withall, whereby theſe bones are moyſtned that they ſhould not grow dry by perpetuall motion. Moreouer in the ſame cauity doe grow theſe griſtly ligaments which in this place doe very ſtrongly binde the *Die bone* to the heele, and therefore when the bones are cleanſed and afterward faſtened together, there remayneth in this place a great diſtance. Sometime alſo on the backeſide it is extended aboue the heele where it bends inward as it were into a double ſmall proceſſe. It hath no appendix for it hath need of equall ſtrength on euery ſide: neither receiueth it the inſertion of muſcles, neither doth it offer originall vnto them.

The ſubſtance of this bone in the original, as alſo of all the other bones of the wreſt of the foote, excepting the heele is a griſtle, but in growne bodies it is on the inſide fungous, yet where the proceſſes break forth, ſolid and denſe, ſauing that it is perforated manifold.

The ſecond bone of the Wreſt [fig. 1 and 2, ᴬ and the whole ſeauen, eight and nine figures] is called in Greeke πτέρνα *Calx*, *calcaneum*, *pedis calcar*, in Engliſh the Heele. This is the greateſt and the thickeſt bone of the whole foot properly ſo called, and was ſo made for more ſtrength and firmitude. For the extention and flexion of the foote are made by the articulation of the *Talus* or Dye-bone to the bones of the Leg and the *brace*. Againe, the motion of the foote to the ſides, is wrought by the coniunction of the *Talus* to the *boate-bone*: the reſt of the connexions of the bones which are many and ſmall do little aſsiſt the former. The ſecond bone of the wreſt. The heele.

As therefore the *Talus* or *paſterne* bone is the principall agent in the motions of the foote, ſo is the heele the principall firmer and eſtabliſher thereof. And vnleſſe the heele had beene greater then the *Talus*, not only the *paſterne* it ſelfe, but the ſhanke alſo would ſlip backward, for it lyeth directly vnder the ſhank and almoſt alone ſupporteth it, and by it the Thigh, and by the Thigh the whole body. It was therefore very neceſſary that it ſhould be a notable large bone, or elſe Nature had beene very improuidēt to lay ſo great a weight vpon it. It behoued alſo that his articulation ſhould be very firme, not wauering or vnſtedfaſt, and therefore Nature ioyned his proceſſes with many hard, griſtly, broade and round ligaments, not onely to the *paſterne* bone but alſo to other bones neare adioyning to make his ſtrength more aſſured. VVherefore it doth not onely lye vnder the *talus* and ſuſtaine it, but is alſo articulated thereto and to the cube. To the *Talus* the vpper part of his large head [fig. 6. 8. 9. ᵖ] entring into the *ſinus* of the *Talus*, [fig. 4. ᵠ] and againe the heele admitteth into a narrow and almoſt plaine *ſinus* of his own [fig. 7. 8. 9. ʳ] the protuberation of the *Talus*: [fig. 9 S] to the Cube bone, it is ioyned on the foreſide [fig. 11. R] by his depreſſed head. [fig 7. ˢ] His vſe.

The lower part of the Heele [fig. 2. ˣʸᶻ] is ſomewhat broad that the foote might ſtand more ſafely; rough alſo and vnequall becauſe of the muſcles. It hath a rough [fig. 2 ʸ fig. 8 ʸ fig. 9. ᶻ] and tranſuerſe proceſſe running from behind downeward, from whoſe foreſide ariſeth the muſcle which benderh the ſecond bones of the foure Toes, and the fleſhy portion, from which are produced the muſcles which leade the foure Toes to the great Toe: wherefore within the proceſſe there is a cauity leaſt when the foot is faſtened vppon the ground, the heads of theſe muſcles ſhould be compreſſed.

The head of the heele or the vpper part thereof in children hath an Appendix, and is like a round body, hauing a light impreſsion rayſed with a little ruggednes, [fig. 7. 8. 9. ᵃᵇ] into which impreſsion the Ligaments of the ſhanke bone and of the *paſterne* are inſerted. On the backſide this vpper part is depreſſed and rough on either hand, [f. 2. 8. 9. ᶜ] in which depreſsion and aſperity the greateſt and ſtrongeſt tendon of the whole body, that is, of the firſt, ſecond and fourth muſcles of the foote is inſerted. On the foreſide it hath rough and deepe boſomes, [figure 7. v v] which with the boſomes of the *paſterne* are filled with griſtles.

The ſides of the heele are broad and depreſſed. The inſide [fig. 2. 8. ᵈᵈ] is ſmmoth and notably ſinewated; in the middeſt are three inſcriptions [figure 2. 8. ᵉ] to make way for the tendons of the fift muſcle of the foote, and the two benders of the laſt ioynts, which paſſe that way vnto the ſole of the foote: that way alſo paſſe the veines, arteries and nerues, which are alſo defended by the proceſſe of the heele which maketh the inſide of the heele very deepe.

The

Table 25. Sheweth the bones of the Foote properly ſo called.

Fig. 1. & 2. ſhewe the bones of the right foote faſtened together their vpper face and their neather face.

Fig. 12. & 13. ſhew the fore and backepart of the wreſt made of foure bones.

TABVLA. XXV.

A B C D 3,5,6, The protuberation of the *Talus* ioyned to the appendix of the leg-bone, and of this protuberation foure ſides.

E E 3, A *ſinus* inſculped in the protuberatiō of the *Talus*.

F F 3, two bunching parts of the protuberation of the *Talus*.

G 3, the innhr ſide of the protuberation of the *Talus* curſted ouer with a griſtle, ioyned to the inner ankle.

H 6, The outward *ſinus* of the protuberation of the *Talus* couered ouer with a griſtle, and receiuing the inner ankle.

I 9, A rough *ſinus* of the *Talus* receiuing a griſtly ligament from the inner ankle.

K 6, a *ſinus* of the *Talus* receiuing a griſtly ligament from the outward ankle.

L M 5,6, two *ſinus* in the hinder part of the *Talus*.

N 3,4,5,6, the neck of the *Talus* or paſtern bone.

O 3,4,5,6, the head of the *Talus* going vnder the *ſinus* of the boate bone.

P 7,8,9, The head of the bone of the heele cruſted ouer with a griſtle and going vnder the *ſinus* of the *Talus* or the paſterne bone.

Q 4, a large *ſinus* of the *Talus* receiuing the head of the heele.

R 7,8,9, a *ſinus* of the heele whereto the lower part of the head of the *Talus* is ioyned.

S 4, the lower part of the head of the *Talus* going into the *ſinus* of the heele.

T T 4, a ſharp *ſinus* of the heele receiuing a griſtly ligament from the paſterne bone.

X Y Z 2, the place of the heele.

Y Z 2, Y 8, Z 9, a proces of the heele made for the production of muſcles.

a b 7,8,9, from *a* to *b* the diſtance of the vpper part of the heele.

c 8,9, the hinder part of the heele.

d 2,8, the inner ſide of the heele.

e 8, the place where the tendons that run to the bottom of the foote are reflected.

f 7,8, the vtter ſide of the heele.

g 1,7,9, here the tendons of the 7 and 8 muſcles of the foote are ſtreched out.

h 7, the fore part of the heele which is ioyned to the paſterne bone.

i 7, that part of the heele which is ioyned to the Cube-bone.

k 11, The *ſinus* of the Boat-bone receiuing the head of the *Talus*. *l m n* 10, three ſurfaces of the Boate bone lightly prominent, which are articulated to the bones of the wreſt. *o p* 11, the vpper part of the Boatbone regarding the top of the foot. *q r* 10, & *q* 11, his lower part. *q* 10,11, A *ſinus* through which the ſixt muſcle of the foote is led. *ſ t u* 13, the plaine ſurfaces of the three inner bones of the wreſt whereby they are articulated to the Boat-bone. *x* 13, a ſhallow *ſinus* of the Cube-bone whereby it is articulated to the heele. *α β* 12, the place of the Cube bone to which that bone of the Afterwreſt is ioyned which ſupporteth the laſt Toe ſaue one. *γ* 12,13, the place of the Cube bone where the third bone of the wreſt is articulated. *δ* 12 13, that part of the Cube bone which reſpecteth the outſide of the foote. *ε* 12,13, the ſurface of the Cube-bone in the vpper part of the foote. *ζ* 2,13, that part of the Cube bone which reguardeth the earth. *η* 2, A *ſinus* of the Cube-bone at which the tendon of the ſeauenth muſcle of the foot is reflected. *B* 13, a proceſſe of the third bone of the wreſt whereinto the fift muſcle of the foot is inſerted. *ι* 12, the place of the inner bone of the wreſt to which that bone of the Afterwreſt which ſuſtayneth the great Toe is coupled. *κ* 12, the place of the ſecond bone of the wreſt whereto the bone of the Afterwreſt that ſupporteth the fore Toe is articulated. *λ* 12, the place of the third bone of the wreſt whereto that bone of the Afterwreſt which ſupporteth the middle Toe is articulated. *μ* 12,

μ,1,2, A ſmall bone whereby that bone of the Afterwreſt which ſuſtaineth the little toe is ioyned vnto the Cube bone. νν 1,2. the diſtances betwixt the Bones of the Afterwreſt. ξξ,1,2, the heades of the bones of the Afterwreſt which enter into the boſomes of the toes. π,2, A proceſſe of the bone of the afterwreſt whereinto the tendon of the ſeauenth muſcle of the foote is implanted. ρ 2, A proceſſe of the Bone of the Afterwreſt, which ſuſtaineth the little toe, which proceſſe receyueth the tendon of the eight muſcle of the Foote. ς,τ,υ,1,2, the three Bones of the foretoe. ϕ,ω,2, two ſeede bones placed vnder that bone of the afterwreſt which ſuſtaineth the great toe. *2 vnder *X*. A Seede bone ſet to the ſecond ioynt of the great Toe. Γ,1,2, The *Talus* or paſterne. Δ,1,2, The Heele. Θ,1,2, the Boat bone. Λ,Ξ,1,2, The bones of the toes Φ,Χ,1,2. Two Bones of the great toe. I,II,III,IV,V,1, The fiue Bones of the Afterwreſt. 1,2,3,4. In fig. 1,2. 12,13, The Foure Bones of the *Tarſus* or the Wreſt. Char. 1. in fig. 12 & 13, the greater wedgbone or the fiſt Bone of the wreſt. Char. 2. fig. 12,13, the leſſer wedge bone or the ſixt bone of the wreſt. Char. 3. fig. 12,13, the middle wedgebone, or the ſeuenth bone of the wreſt. Char. 4 fig. 12,13, The Cube-bone.

The outſide [fig. 2,9 Z] is depreſſed, rough and vnequall, out of whoſe lower part yſſueth the muſcle which leadeth the little Toe from the reſt, but in the foreſide there is a little ſinus [fig. 1,7,9 S] cruſted ouer with a Griſtle, which we meet withall vnder a ſmal proceſſe, and through this ſinus the tendons of the ſeuenth and eight muſcles of the ſole do paſſe and are reflected vnto the backſide of the vtter ankle. That part of the heele that is next the little Toe is on the foreſide ſmooth by reaſon of a griſtle wherewith it is cruſted ouer, and the vpper part ſhooteth out a large head raiſed ſomewhat high, by which head the heele is articulated into a ſinus of the Cube-bone almoſt plaine, [fig. 1,2 Θ] belowe it hath an oblique Sinus bending inwarde, which receyueth a part of the Cube-bone.

The third bone of the wreſt [figu. 10, 11] is called by the Grecians σκαφοειδὲς *Nauiforme*, *Os Nauiculare Cymba* the Boat-bone, becauſe it is long, deepe, behinde hollowe, before and in the vpper part gibbous, [fig. 1, °p] in the lower part hollow. [fig. 10, 11, qr] This *Bote-bone* is ſeated in the inſide of the foote, and by the mediation thereof, the greateſt part of the wreſt is ioyned to the *Talus*. For on the backſide it hath a Sinus [figure. 11, k] deep and tranſuerſely long, [fi. 1 olmn] in which the head of the *talus* [fig. 3,4,5,O] is inſerted, and this articulation muſt be referred to an obſcure *Enarthroſis* or *Inarticulation*, becauſe the motion thereof is obſcure. The other part hath a long head bunching out, and diſtinguiſhed with a threefold ſuperficies or ſurface [fig. 10, l m n] to which the three laſt bones are articulated, [fig. 1,2,12,13. char. 1,2,3] but becauſe they are very ſmooth, it is to be doubted whether they receiue or are receyued. The 3. bone of the Wreſt.

The outſide of this Boate-bone is large, round and ſinuated [fig. 10, qr and 11q] eſpecially where it is ioyned to the fiſt bone. Preſently after, it is anguſtated by degrees, and endeth into an internall narrow proceſſe [Fig. 10, q] reſembling the prow of a ſhip. The inſide is prominent, ſo that it maketh a notable protuberation, which protuberation maketh the lower Sinus [Figu. 10, 11 q] ouer which it hangeth much greater vvhere the tendon of the ſixt muſcle of the foote is reflected. Finally this Boat-bone is rough aboue and below, that from thence the Ligaments might yſſue which tye this bone to the *Talus*, and the bones of the wreſt of the foote.

Theſe three bones whereto there is nothing aunſwerable in the hand, and are as it were the baſis of the leg, the Ancients haue not numbred among the bones of the wreſt of the foote. There follow other foure, which ſay they, do alone make the *tarſus* or wreſt, and are like vnto the wreſt of the hand; for being ioyned together by Ligamentes, they make as it were an Arch, whoſe vpper ſuperficies is conuexe, & the lower concauous or hollow: for the Cube-bone is ioyned to the heele, and the three following to the Boate-bone, and with them are together lifted vp from the earth, for ſuch a conſtruction as this is ſtronger both for the faſtening of the foote and ſuſtaining of the hodye, for an arched building is more ſtrong and laſting. Theſe bones alſo were neceſſarily prominent, that vnder ſuch prominences a cauity ſhould be left, wherein as wel the tendons of thoſe muſcles ſhould be ſecured which run vnder the ſole, as alſo the muſcles themſelues which ariſe from the lower part of the wreſt, and are directed to the toes of the foote: for if the ſole had bene plaine, the Muſcles with their tendons would haue bene compreſſed, and ſo neither could a man haue trauelled without paine, and beſides the muſcles had beene kept from performing their office in flexion and extention.

Moreouer, where theſe bones are ioyned one to the ſides of another, they are not couered ouer with griſtles, ſauing onely where they beare vppon the Boate-bone. Otherwhere they are coupled with griſtly Ligaments. They are alſo without appendices, and

their ſubſtance is like the ſubſtance of the paſterne and Boat-bones. They differ alſo in quantity and figure, [conferre Fig.1 with 2. and 12 with 13] for the two firſt are far greater then thoſe two in the middeſt, and are ioyned to the foure bones of the *Pedium* or After-wreſt, but we will intreate of them particularly.

The 4. bone. The fourth bone of the wreſt [Fig.12,13.char.4] is called in Greeke κυβοειδὴς *Os Cubiforme* from the forme of a Dye, becauſe it hath as it were ſix ſides. It is alſo called πολύμορφον, *Os Miltiforme*, becauſe it hath diuers formes, the Arabians call it *Grandinſonm*. This bone on the outſide of the foote is placed before the heele. It is greater then the reſt, & the firſt ſide of it [Fig.13 ˣ] is ioyned behinde to the heele [Fig. 7, ⁱ] with an vnequall ſurface and reſteth vpon the ground, and it is doubtfull whither it receyue or be receyued. *Archangelus* affirmeth both: the ſecond ſide, [figu.12 αβ] before is ioyned with a continuall ſuperficies to the fourth and fift bones of the After-wreſt, and ſupporteth them like a baſis: the third ſide is inward [fig.12,13 γ] and articulated to the ſeauenth bone of the wreſt; the fourth ſide is outward [fig.12,13, ᵈ] and obſcurely plaine, neither doth it ioyn to any bone, no more then the two following ſides do, for the fift ſide is aboue plain and rough [fig.12,13 ε] and the ſixt is below. [fig.2 ζ, fig.3 ζ] Finally, the latter end or extremity of it hath a proceſſe diuided by a middle ſinus, [fig.2, η] which is long and oblique, whereat the tendon of the ſeuenth muſcle of the foote is reuolued.

The 5. bone. The fift bone of the wreſt [Fig.12, char.1, fig.13 ᶜ] as alſo the two following, are called in Greeke χαλκοειδῆ *Cuneiformes*, becauſe they are like wedges. This fift, occupyeth the inſide of the foote, and is ſeated ouer againſt the great toe. On the foreſide it is ſinuated [Fig.13, γ] to receiue a portion of the proceſſe of the Boatbone; behind, it receiueth the firſt bone of the *pedium* or Afterwreſt, and it is vncertain whether it be ſinewated or prominent, which vncertainty is common to the backeward bones, as they are coupled either one with another, or with the bones of the After-wreſt, ſo that they ſeeme to be conioyned by *Ginglymos*, becauſe they haue obſcure Sinus or boſomes, notwithſtanding this part ſeemeth to haue two ſmall knots or protuberations, becauſe the bone of the Afterwreſt carrieth the ſhew of a double cauity: the vpper part is but ſmall and a litle conuex, whereby it is ioyned to a ſhallow or ſuperficiary Sinus of the ſixte bone: the lower ſide is thicker, that it might reſt faſter vpon the ground.

The 6 bone. The ſixt bone of the wreſt [fig.12,13.char.2,7] is called *Cuneiforme minus*, the leſſer wedge, and if you regard the vpper part which looketh toward the foote it is broade, ſomewhat arched, and as it were foure-cornered. If you reſpect the lower part which looketh toward the foote it is very narrow and edged, and ſo reſembleth a wedge, as alſo doth the ſeauenth which is next vnto it, for they both ſeeme to be like wedges interpoſed amongſt the reſt to ioyne them the faſter together. This ſixt bone behind is ioyned to the Boate-bone: [Fig.13 ᵉ] before it lightly buncheth out and is faſtened to the ſecond bone of the After-wreſt; [Fig.12 ϰ] on the inſide it is ioyned with the outſide of the fifte bone of the wreſt, and on the outſide with the outſide of the ſeuenth.

The 7 bone. The ſeuenth bone of the wreſt [Fig.12 & 13.char:31] is called *Cuneiforme medium*, the middle wedge, and is ſeated betwixt the fourth and the ſixt. It is ſome-what like a Quadrangle but longer, for on the backſide it hath a ſmall ſinus [Figu.13, ᵃ] which receyueth the protuberation of the Boat-bone: on the foreſide it admitteth the thirde bone of the Afterwreſt, [Fig.12 λ] and the ſides of it touch the ſides of the ſixt and the fourth Bones. And thus it is placed amongſt the bones like a wedge: below it ſwelleth out with a protuberation, [Fig:13, θ] whereinto the fift muſcle of the foote is inſerted.

[The twelfth Figure ſheweth the anteriour face of the foure bones of the wreſt, of the foote faſtened together, the thirteenth Figure ſheweth their backſide]

CHAP. XXXVII. *Of the Bones of the After-wreſt, and the Toes of the Feete.*

The afterwriſt of the foote. THE ſecond patt of the Foot is called μέσον by the Grecians, by *Celſus Planta*, the tread of the Foote, by others *peſten*, and by others *Matatarſum*, becauſe it is anſwerable to the *Metacarpium* in the hand, we will call it *the Afterwreſt of the Foote*. [Tab.25.fig.1, Char.I,II,III,IV,V] It is compounded of fiue bones which are articulated to the Bones of the *Tarſus* or wreſt, and do ſuſtaine the bones of the Toes. To the *Tarſus* or wreſt they are ioyned by ſomewhat plaine and ſmooth ſuperficies. [Fig:12,2, ϰ, λ, α, β]

The

The firſt which is placed before the great toe, is *adarticulated* to the inner bone of the wreſt; that which is placed before the next to the great toe, is ioyned to the ſecond bone of the wreſt; that which is placed before the middle toe to the third, [fig. 2 betwixt ρ, ω] the other two are adarticulated to the Cube-bone. [Fig. 2 neere ρ and ν] And as the bones of the VVreſt of the foote are not placed on the foreſide in a right line, ſo of the bones of the After-wreſt one enclineth more backward then another. Notwithſtanding, they ſtand in one order or ranke as do the bones of the Toes, which maketh much to ſtability and firmitude.

They are long bones and round, and end on both ſides into heads. For where they are articulated with the bones of the wreſt they are thicke and ſinewated and ioyned together by their ſides, where they recede or depart by degrees one from another, they become ſlender and leaue a diſtance betweene them for the Muſcles called *Interoſſei*, which wee called the *Bone-bound* Muſcles. But their lower heads which are inſerted into the deepe boſomes of the firſt ioynts of the Toes [fig. 1, 2 ξ in ο] are orbicular, and on the backſide encreaſed with an Appendix. The heads of theſe bones are more diuided towards the vpper part and leſſe toward the lower, quite contrary to that it is in the handes, and the reaſon was becauſe in detxention it behooued that the Toes of the feete ſhould be more eleuated then the fingers of the hand, which kinde of articulation we call *Enarthroſis* or *Inarticulation*.

The firſt of theſe that is ſet before the great toe, is the thickeſt of them all & the ſhorteſt, hauing a roũnder head, that ſo the great toe might bee better mooued to the ſides then any of the reſt. In the lower part vnder the heade, where it is articulated vvith the *Tarſus* or wreſt it buncheth out into a proceſſe [fig. 2 π] wherevnto is inſerted the tendon of the ſeuenth muſcle of the foote, and at the ſame place there are two Seedebones greater then the reſt, and cruſted ouer with a griſtle. The firſt.

The ſecond bone of the Afterwreſt which ſuſtaineth the foretoe is the longeſt, vnleſſe it be the fift which ſuſtaineth the little toe; for the length of this laſt is encreaſed by a notable proceſſe, [figure. 2 ρ] whereby it was articulated to the wreſt, becauſe it was to bee lengthned into the outſide of the foote to make a place of implantation for the tendon of the eight muſcle of the foote. Theſe bones of the Afterwreſt aboue and belowe, haue Appendices cruſted ouer with griſtles: their ſubſtance alſo and their cauity which conteyneth their marrow is anſwerable to the ſubſtance and cauity of the bones of the Afterwreſt of the Hand. Moreouer they are thrilled with ſmall holes, by which little veines and arteries, as in other bones, do paſſe in to nouriſh and cheriſh them. The Bones of the Toes.

After the bones of the Afterwreſt doe follow the bones of the toes which make the third part of the foote and are in number fourteene [fig. 1 ^ Ξ. fig. 2 Λ, Ξ] for euerie one of them conſiſteth of three bones, as it is in the fingers of the hand excepting the great toe; [fig. 1, 2, ϛ τ υ] and indeed their ſubſtance, ſtructure and ſituation is litle different from the hãd, ſauing that the firſt ioynts haue a deeper ſinus becauſe the deeper heads of the bones of the *Pedium* or Afterwreſt are inſerted into them. And although the heads of the bones of the foot are large, yet is not their ſinus ſo large as in the hands, that ſo in extention the toes might be more lifted vp, and yeeld ſomething to the ground vpon which we ſtande. The great toe is formed of two bones [fig. 1 ο χ] that the foreſide of the cauity of the Afterwreſt might more firmely reſt vpon the earth. All theſe Bones aboue and below haue Appendices, and are cruſted ouer with ſtrong griſtles to make the ioynt more glib which is articulated by *Ginglymos*, alwayes excepting the laſt bones of the toes, which are not articulated to any other bone, but haue nayles cleauing vnto them. Note alſo, that the knuckles of the toes are ſhorter then thoſe of the hands, gibbous aboue and hollowe belowe, the better to admit the Tendons of the muſcles which bend the ſecond and thirde ioynts. Againe, the firſt bones are greater then the ſecond, and the ſecond greater then the third, and the middle bone in foure toes ſeemeth to be ſquare. In like manner, the bones of the great toe are thicker then the bones of the thumbe: the reſt of the bones of the toes are leſſer then the bones of the fingers. Finally, the bones of the toes are alſo full of marrow.

CHAP. XXXVIII. *Of the Seed-bones and the Nayles.*

THE Seed-bones [t. 25. f. 2 ϕ ω] are of the ſame number and poſition with the Seedebones in the hands, that is to ſay twelue, and they are ſo much leſſe and leſſe conſpicuous in the toes then they are in the fingers, as the fingers are greater then the toes: not-

withſtanding as the great toe hath greater bones thē the thumb, ſo alſo are his ſeedbones larger. Wherefore at the firſt ioynt of the great toe nere the head of the bone of the Afterwreſt which is articulated to that ioynt, there are two notable ſeede-bones which lye vnder the nerious part of the muſcle which bendeth the firſt bone of the great toe: and of theſe the inner is bigger almoſt by halfe then the other, yea as big as half a great peaſe when the huſk is off, and not much vnlike it. This bone the Arabians call *Albadara*, and they ſay (how fooliſhly let the Diuines ſpeake) that of this bone as it were of ſeed a man receyueth the new body wherewith he riſeth at the reſurrection; that which lieth vnder the ſecond ioynt of the great toe and is much leſſe then the former, leaneth vppon the tendon of the muſcle which bendeth the ſecond bone of the great toe.

Cōcerning the reſt of the ſeedbones, they are diſpoſed as is ſaid in the hiſtory of the hand.

2 Seed bones in the Hand. To this place wee thought good to refer two ſmall bones found in the Ham neere the thigh-bone, and growing to the heads of the two firſt muſcles which mooue the Foote. Theſe bones, ſaith *Veſalius*, are found in Harts, in Dogs, and Hares, and ſuch like dry creatures, yea in old men alſo. Their ſurface is ſlippery and regardeth the vpper part of the lower heads of the thigh, to which bones this is peculiar, that they do not leane vppon the tendons of the muſcles as other ſeed-bones do, but vpon their originals, like as doth the bony part which in old men is faſtned to the Cube-bone, which bony part we meet withall in the tendon of the ſeauenth muſcle of the foote there reflected.

Furthermore, as we ſaid before, that to the outſide of the ioynt, whereat the bones of the Afterwreſt which ſuſtaineth the little finger is faſtned to the wreſt, there is a ſmall bone annexed, ſo alſo in the foot at the outſide of the articulation of that bone of the Afterwreſt of the foote which ſupporteth the little toe [ta.25.f.1,2,μ] where the fifte bone of the Afterwreſt is articulated to the Cube-bone, there is alſo found a ſmall bone at the inſertion of the tendon of the eight muſcle of the foot.

Their vſe. Theſe ſeed-bones, although they ſeem to haue the ſame vſe that they haue in the hands; yet moreouer in the foot they are the cauſe why whē we ſtand or walk, whether the place be rough or ſmooth, the foot applies it ſelfe more equally vnto the earth: as alſo to keepe the toes when we ſtand or walke, from being luxed by ſtones or any other eminent thing we ſhold light vpon. Finally, the extremities or ends of the toes as it is in the Fingers, are couered and defended with nayles faſtned to the skin on the outſide, of which we will add a few words. The Nayles are called by the Grecians ὄνυχες, their root ῥίζονυχία, the bottome or white moone ἀνατολή, and the filme that groweth to the root ἀργαμώνη. There are diuers opinions concerning the matter of the Nailes: ſome thinke, it is a glutinous moyſture parched and dryed by the heate, and driuen vnto the extreame parts, and therefore ſaith *Hippocrates* are the nailes exceeding faſt and thight, beeeauſe their matter is baked together. Secondly *Empedocles* conceiued, that the nails were made of nerues by congealation, and therefore *Fœſius* in his notes vpon *Hippocrates* cals the nailes *Neruorum clauſulas ſummas*, the terminations of the nerues giuen by Nature to make vp and eſtabliſh the extremities of the body, and therefore if they faile or fall away it is a ſigne of great weakneſſe. Thirdly *Ariſtotle* in the ſixt chap. of his 2 book *de generatione animal.* ſaith, that the nailes, the hayres, hornes, beakes of birdes, hooues and ſuch like are engendred of aduentitious aliment. Fourthly *Columbus* remembers, that ſome thinke the nailes are amaſſed of a part of a bone of a nerue of skin, yea ſome ſay alſo of fleſh, but he doth not eaſily ſubſcribe to their conceite.

The Nailes.

Diuers opinions of their generation.

Columbus ſaith, they take their originall partly from the skin, partly from the tendons of the muſcles which extend the Fingers and the toes. *Bauhine* ſaith, that ſome conceyue them to ariſe from the craſſe excrements of the third concoction, and therfore that they continually grow by an imperfect acretion, made by the appoſition onely or addition of Aliment, whence, ſay they, it is that they grow onely in length, not in bredth or depth, and therefore are to be excluded out of the number of liuing parts; notwithſtanding *Galen* in his booke *de Admin. Anatom.* witneſſeth, that there is conueyed to the roots of the nailes, a vein, an artery and a nerue, by which they receiue aliment, life and ſenſe, as other parts do. And truly, not onely two Nerues are conueyed vnto the roots of the nailes, but alſo do creepe vnder the nailes together with the veines vnto the very top of the Finger: yet we do not ſay that the nailes haue ſenſe, becauſe they are not diſtributed throughout the ſubſtaunce of the nailes no more then are the veines which vnburthen themſelues of the Aliment at the roote of the naile. We conclude therefore that the nailes are encreaſed

sed like the teeth by an appoſition of aliment to their roote, which was the beſt way, becauſe they were euery day worne and therefore had more neede to bee reſtored in theyr length then in their bredth and thickneſſe.

Their ſubſtance is of a middle Nature betwixt bones and griſtles moderately hard, the better to beare the violence of outward iniures, flexible or buxome that they ſhould not breake but giue way to violence, pellucide or tranſparant and therefore they are either red or liuid according to their fleſh vnder them: thin they are and conuex, that they might lye more ſnogly vpon the fingers, and this alſo maketh much for their ſecurity; for if they ſtood off from the fleſh they would eaſily be torn from their roots. Again, to make them more ſtedfaſt, they are faſtned at their root with a Ligament, & becauſe they muſt needs grow to the fleſh and the skin, therefore the skinne on the outſide compaſſeth the root round, but the fleſh groweth to them more inward. Vnder the nailes as far as to the very extremities or ends of the fingers the tendons of muſcles doe paſſe and are dilated vnder them, which thing, ſaith *Columbus*, I firſt obſerued. And this is the reaſon why the part vnder them is of ſo exquiſite ſenſe, and the pain ſo great if any ſharpe ſplinter or ſuch like do get vnder the naile. Their ſubſtance.

The vſe of the nailes is to defend the end of the fingers which are very ſofte, that they be not offended by outward occurrents: their hardneſſe therfore giueth a firmitude vnto the ſoftneſſe of the fleſh. Againe, the hands had nayles for better apprehenſion, for wee could not haue taken hold of many ſmall things vnleſſe there had bene faſtned ſome hard body to ſtrengthen & eſtabliſh the fleſhy extremities of the Fingers, which muſt bee alſo ſharpe or edged to encloſe a fine and ſlender bodye, that otherwiſe would haue ſlipped from betwixt them. The Toes had nayles to couer and defend their extremities, & beſide in ſtation to beare the Toes againſt the ground with more reſiſtance. As for ſcratching or clawing, or any ſuch other vſe of the nailes, we thinke it to be of the *by* and not of the *Maine*. The Vſe.

Thus at length haue we, through the diuine aſsiſtance, brought vnto end a long and painfull labour, worthy indeede to haue bene vndertaken by a man of more ſufficiencie and of greater experience in this Art then I would haue my ſelfe eſteemed to be; my Age and Meanes not affoording me time or opportunities to do that which I haue earneſtlie euer affected. But for recompence of theſe Defects (gentle Reader) I haue preſſed the footſteps of the beſt and moſt approoued Authors; wherein as my firſt and moſt ſimple intent was the bettering of my owne knowledge in ſo neceſſary a part of my profeſsion, ſo being perſwaded that thy profit might fall in with the ſame, I haue ſet before thee a Mirrour, wherein thou mayſt ſee the true repreſentation of thine owne Originall, Structure, Growth and Accompliſhment; & learn thereby to giue the glory and profit of thy Creation, to him that acording to his mighty vvorking did firſt poure thee forth as a few drops of Milke and after curdled and ſammed thee vppe into ſo exquiſit a forme as thou art become the moſt wonderfull of all his workes of wonder. To him therefore ſo admired and propitious a Creator, aſcribe with me all honor and praiſe, and conſecrate the glorious Temple of thy body, and the Altar of thy Soule vnto that Diety, vvho created them firſt of nothing, redeemed them when they were worſe then naught, and hath promiſed eternall manſions for them, to partake with Himſelfe of euerlaſting Felicitie. The Concluſion.

Πάντοτε δόξα Θεῷ.

FINIS.

The Printer to the Reader.

WHen I intended firſt this excellent labour (Courteous Reader) my abſolute purpoſe aymed at the ingenious worke of M. *Ambroſe Parœ*, (Chirurgeon to the moſt Chriſtian King of France, *Henrie* the third) a man of admirable perfection in his Art and profeſſion; whereto I was the rather incited, becauſe his firſt fiue Bookes beginneth with this preſent Argument of Anatomy, a matter much affected by mee. But finding his ſcope farre ſhort of ſo deliberate a determination, & that more mature diſcourſe flowed from thoſe two famous Anatomiſts, *Iaſpar Baubinus* and *Andreas Laurentius*, with diuers other Authors writing on the ſame argument, I made choiſe for this time to be gouerned by their worthy enſtructions; although to my no meane care and coſt it hath riſen to ſo great a volume, which (in the firſt intention) was imagined to comprize the whole frame or building. Yet let me not be miſinterpreted heerein, as one fearefull to aduenture on a worke of farre greater moment, the Authors being ſo renowned, and the expectation only to the publique benefit of my countrey. For thus much I aſſure thee, the Figures, Pieces, and Shapes belonging to the remaining Bookes of *Paræs* Chirurgery, are already prepared, & the worke it ſelfe fully tranſlated for the preſſe, which by thy gentle acceptance of this my firſt aduenture in this kinde, will flye vnto thee with the ſwifter ſpeed.

Farewell.
